SEAMANSHIP.

THE present article will be found to embrace a threefold division of the subject of seamanship. The reader will find, in the first portion, those general principles which are applicable alike to all cases, and suited to all times of the past and present state of naval affairs. The second portion will be closely connected with this, and will, in fact, consist of a description of some manœuvres, of which the object is to illustrate and further explain the theory previously laid down. Whilst the third portion will bring up the knowledge of the subject in its improved condition, and deal with all those questions which the invention of chain cables, steam, as applied to marine engines, the new system of signals, and other discoveries have introduced into nautical affairs during the last fifty years; avoiding minute details, when they are given under the separate heads in other parts of this work. We commence, therefore, with the great facts and principles of seamanship, in its most general bearing and aspect.

Definition.

By this word we express that noble art, or, more properly, the qualifications which enable a man to exercise the noble art of rigging and working a ship. A SEAMAN, in the language of the profession, is not merely a mariner or labourer on board a ship, but a man who understands the structure of this wonderful machine, and every subordinate part of its mechanism, so as to enable him to employ it to the best advantage for pushing her forward in a particular direction, and for avoiding the numberless dangers to which she is exposed by the violence of the winds and waves. He also knows what courses can be held by the ship, according to the wind that blows, and what cannot, and which of these is most conducive to her progress in her intended voyage; and he must be able to perform every part of the necessary operation with his own hands.

Importance and difficulty of the art;

We are justified in calling it a *noble art*, not only by its importance, which it is quite needless to amplify or embellish, but by its immense extent and difficulty, and the prodigious number and variety of principles on which it is founded, all of which must be possessed in such a manner that they shall offer themselves without reflection in an instant, otherwise the so-called seaman, whatever be his pretensions, cannot be trusted in charge of a watch.

Seamanship.

The art is practised, to a certain extent, by persons without what we call *education*, and in the humbler walks of life, and therefore it suffers in the estimation of the careless spectator. It is thought little of because little attention is paid to it. But if multiplicity, variety, and intricacy of principles, and a systematic knowledge of these principles, entitle any art to the appellation of *scientific* and *liberal*, seamanship claims these epithets in an eminent degree. We are amused with the pedantry of the seaman, which appears in his whole language. Indeed, it is the only pedantry that amuses. A scholar, a soldier, a lawyer, nay, even the elegant courtier, would disgust us, were he to make the thousandth part of the allusions to his profession that is well received from the seaman; and we do the seaman no more than justice. His profession *must* engross his whole mind, otherwise he can never learn it. A sailor, although uneducated, may possess a prodigious deal of knowledge; but cannot tell what he knows, or rather what he feels, for his science is really at his finger-ends. We can say with confidence, that if a person of education, versed in mechanics, and acquainted with the structure of a ship, were to observe with attention the movements which are made on board a first or second rate ship of war during a shifting storm, under the direction of an intelligent officer, he would be rapt in admiration.

What a pity it is that an art so important, so difficult, and so intimately connected with the invariable laws of mechanical nature, should be so held by many of its possessors, that it cannot improve, but must die with each individual. Having no advantages of previous education, they cannot scientifically arrange their thoughts. They can far less express or communicate to others the intuitive knowledge which they possess; and their art, acquired by habit alone, is little different from an instinct. We are not entitled to expect much improvement here; yet a ship may be considered as a machine. We know the forces which act on it, and we

know the results of its construction; all these are as fixed as the laws of motion. What hinders this to be reduced to a set of practical maxims, as well founded and as logically deduced as the working of a steam-engine or a cotton-mill? The stoker or the spinner acts only with his hands, and may "whistle as he works, for want of thought;" but the mechanist, the engineer, thinks for him, improves his machine, and directs him to a better practice. May not the seaman look for the same assistance; and may not the ingenious speculist in his closet unravel the intricate thread of mechanism which connects all the manual operations with the unchangeable laws of nature, and both furnish the seaman with a better machine, and direct him to a more dexterous use of it.

which has been zealously cultivated by the French philosophers.

We cannot help thinking that much may be done; nay, we may say that much has been done. We think highly of the progressive labours of Renaud, Pitot, Bouguer, Du Hamel, Groignard, Bernoulli, Euler, Romme, and others; and are both surprised and sorry that Britain has contributed so little in these attempts. Gordon is the only one of our countrymen who has given a professedly scientific treatise on a small branch of the subject. The government of France has always been strongly impressed with the notion of great improvements being attainable by systematic study of this art; and we are indebted to the endeavours of that ingenious nation for any thing of practical importance that has been obtained. M. Bouguer was professor of hydrology at one of the marine academies of France, and was enjoined, as part of his duty, to compose dissertations both on the construction and the working of ships. His *Traité du Navire* and his *Manœuvre des Vaisseaux*, are undoubtedly very valuable performances. So are those of Euler and Bernoulli, considered as mathematical dissertations; and they are wonderful works of genius, considered as the productions of persons who hardly ever saw a ship, and were totally unacquainted with the profession of a seaman. In this respect Bouguer had great superiority, having always lived at a sea-port, and having made many very long voyages. His treatises, therefore, are infinitely better accommodated to the demands of the seaman, and more directly instructive; but still the author is more a mathematician than an artist, and his performance is intelligible only to mathematicians. It is true, the academical education of the young gentleman of the French navy is such, that a great number of them may acquire the preparatory knowledge that is necessary; and we are well informed that, in this respect, the officers of the British navy are greatly inferior to them. At the same time, we may observe, that the French themselves appear so little sensible of the advantage of these publications, that no person among them has attempted to make a familiar abridgment of them, written in a way fitted to attract attention; and they still remain neglected in their original abstruse and uninteresting form; in consequence of which, these very ingenious and learned dissertations are by no means so useful as we should expect. They are large books, and appear to contain much; and as their plan is logical, it seems to occupy the whole subject, and, therefore, to have done almost all that can be done. But, alas! they have only opened the subject, and the study is yet in its infancy. The whole science of the art must proceed on the knowledge of the impulsions of the wind and water. These are the forces which act on the machine; and its motions, which are the ultimatum of our research, whether as an end to be obtained or as a thing to be prevented, must depend on these forces. Now it is with respect to this fundamental point that we are as yet almost totally in the dark. And in the performances of M. Bouguer, as also in those of the other authors we have named, the theory of these forces, by which their quantity and the direction of their action are ascertained, is altogether erroneous; and its results deviate so enormously from what is observed in the motions of a ship, that the persons who should direct the operations on shipboard, in conformity to the maxims deducible from M. Bouguer's propositions, would be baffled in most of his attempts, and be in danger of losing the ship. The whole proceeds on the supposed truth of that theory which states the impulse of a fluid to be in the proportion of the square of the sine of the angle of incidence; and that its action on any small portion, such as a square foot of the sails or hull, is the same as if that portion were detached from the rest, and were exposed, single and alone, to the wind or water in the same angle. But it can be shown, both from theory and experience, that both of these principles are erroneous, and this to a very great degree, in cases which occur most frequently in practice, that is, in the small angles of inclination. When the wind falls nearly perpendicular on the sails, theory is not very erroneous; but in these cases, the circumstances of the ship's situation are generally such that the practice is easy, occurring almost without thought; and in this case too, even considerable deviations from the very best practice are of no great moment. The interesting cases, where the intended movement requires or depends upon very oblique actions of the wind on the sails, and its practicability or impracticability depends on a very small variation of this obliquity; a mistake of the force, either as to intensity or direction, produces a mighty effect on the resulting motion. This is the case in sailing to windward, the most important of all the general problems of seamanship. The trim of the sails, and the course of the ship, so as to gain most on the wind, are very nice things; that is, they are confined within very narrow limits, and a small mistake produces a very considerable effect. The same thing obtains in many of the nice problems of tacking, box-hauling, wearing after lying-to in a gale of wind, &c.

Argument against the utility of their performances;

which are confessedly erroneous in their fundamental principles;

The error in the second assertion of the theory is still greater, and the action on one part of the sail or hull is so greatly modified by its action on another adjoining part, that a stay-sail is often seen hanging like a loose rag, although there is nothing between it and the wind; and this merely because a great sail in its neighbourhood sends off a lateral stream of wind, which completely hinders the wind from getting at it. Till the theory of the action of fluids be established, therefore, we cannot tell what are the forces which are acting on every point of the sail and hull; therefore we cannot tell either the mean intensity or direction of the whole force which acts on any particular sail, nor the intensity and mean direction of the resistance to the hull; circumstances absolutely necessary for enabling us to say what will be their energy in producing a rotation round any particular axis. In like manner, we cannot, by such a computation, find the spontaneous axis of conversion, or the velocity of such conversion. In short, we cannot pronounce with tolerable confidence *à priori* what will be the motions in any case, or what dispositions of the sails will produce the movement we wish to perform. The experienced seaman learns by habit the general effects of every disposition of the sails; and though his knowledge is far from being accurate, it seldom leads him into any very blundering operation. Perhaps he seldom makes the best adjustment possible, but seldomer still does he deviate very far from it; and in the most general and important problems, such as working to windward, the result of much experience and many corrections has settled a trim of the sails, which is certainly not far from the truth, but it must be acknowledged, deviates widely and uniformly from the theories of the mathematician's closet.

After this account of the theoretical performances in the art of seamanship, and entertaining, as we do, small hopes of seeing a perfect theory of the impulse of fluids, it will not be expected that we enter very minutely on the subject in this place; nor is it our intention. But let it be observed that the theory is defect-

Seamanship.

ive in one point only; and although this is a most important point, and the errors in it destroy the conclusions of the chief propositions, the reasonings remain in full force, and the *modus operandi* is precisely such as is stated in the theory. The *principles* of the art are therefore to be found in these treatises; but false inferences have been drawn, by computing from erroneous quantities. The rules and the practice of the computation, however, are still beyond controversy. Nay, since the process of investigation is legitimate, we may make use of it in order to discover the very circumstance in which we are at present mistaken; for by converting the proposition, instead of finding the motions by means of the supposed forces, combined with the known mechanism, we may discover the forces by means of this mechanism and the observed motions.

though use may be made of them.

Design of this article.

We shall, therefore, in this place, give a very general view of the movements of a ship under sail, showing how they are produced and modified by the action of the wind on her sails, the water on her rudder and on her bows. We shall not attempt a precise determination of any of these movements; but we shall say enough to enable the curious landsman to understand how this mighty machine is managed amidst the fury of the winds and waves; and, what is more to our wish, we hope to enable the thinking seaman, to generalise that knowledge which he possesses; to class his ideas, and give them a sort of rational system; and even to improve his practice, by making him sensible of the immediate operation of everything he does, aud in what manner it contributes to produce the movement which he has in view.

A ship considered as in free space, impelled and resisted by opposite forces.

A ship may be considered at present as a mass of inert matter in free space, at liberty to move in every direction, according to the forces which impel or resist her; and when she is in actual motion, in the direction of her course, we may still consider her as at rest in absolute space, but exposed to the impulse of a current of water moving equally fast in the opposite direction; for in both cases the pressure of the water on her bows is the same; and we know that it is possible, and frequently happens in currents, that the impulse of the wind on her sails, and that of the water on her bows, balance each other so precisely, that she not only does not stir from the place, but also remains steadily in the same position, with her head directed to the same point of the compass. This state of things is easily conceived by any person accustomed to consider mechanical subjects, and every seaman of experience has observed it. It is of importance to consider it in this point of view, because it gives us the most familiar notion of the manner in which these forces of the wind and water are set in opposition, and made to balance or not to balance each other by the intervention of the ship, in the same manner as the goods and the weights balance each other in the scales by the intervention of a beam or steelyard.

Impulse of the wind on the sails opposite to that of the water on the bows.

When a ship proceeds steadily in her course, without changing her rate of sailing, or varying the direction of her head, we must in the first place conceive the accumulated impulses of the wind on all her sails as precisely equal and directly opposite to the impulse of the water on her bows. In the next place, because the ship does not change the direction of her keel, she resembles the balanced steelyard, in which the energies of the two weights, which tend to produce rotations in opposite directions, and thus to change the position of the beam, mutually balance each other round the fulcrum; so the energies of the actions of the wind on the different sails balance the energies of the water on the different parts of the hull.

Skill of the seaman displayed in shaping his course.

The seaman has two principal tasks to perform. The first is to keep the ship steadily in that course which will bring her farthest on in the line of her intended voyage. This is frequently very different from that line, and the choice of the best course is sometimes a matter of considerable difficulty. It is sometimes possible to shape the course precisely along the line of the voyage; and yet the intelligent seaman knows that he will arrive sooner, or with greater safety, at his port, by taking a different course; because he will gain more by increasing his speed than he loses by increasing the distance. Some principle must direct him in the selection of this course. This we must attempt to lay before the reader.

Having chosen such a course as he thinks most advantageous, he must set such a quantity of sail as the strength of the wind will allow him to carry with safety and effect, and must trim the sails properly, or so adjust their positions to the direction of the wind, that they may have the greatest possible tendency to impel the ship in the line of her course, and to keep her steadily in that direction.

His other task is to produce any deviations which he sees proper from the present course of the ship; and to produce these in the most certain, the safest, and the most expeditious manner. It is chiefly in this movement that the mechanical nature of a ship comes into view, and it is here that the superior address and resources of an expert seaman is to be perceived.

Under the article SAILING, some notice has been taken of the first task of the seaman, and it was there shown how a ship, after having taken up her anchor and fitted her sails, accelerates her motion, by degrees which continually diminish, till the increasing resistance of the water becomes precisely equal to the diminished impulse of the wind, and then the motion continues uniformly the same, so long as the wind continues to blow with the same force, and in the same direction.

It is perfectly consonant to experience, that the impulse of fluids is in the duplicate ratio of the relative velocity. Let it be supposed that when water moves one foot per second, its perpendicular pressure or impulse on a square foot is m pounds. Then, if it be moving with the velocity V estimated in feet per second, its perpendicular impulse on a surface S, containing any number of square feet, must be $m\,SV^2$.

In like manner, the impulse of air on the same surface may be represented by $n\,SV^2$; and the proportion of the impulse of these two fluids will be that of m to n. We may express this by the ratio of q to 1, making $\frac{m}{n}=q$.

Impulse of the water computed in ounces on the square foot.

M. Bouguer's computations and tables are on the supposition that the impulse of sea-water moving 1 foot per second is twenty-three ounces on a square foot, and that the impulse of the wind is the same when it blows at the rate of 24 feet per second. These measures are all French, and by no means agree with the experiments of Buat and others, whose conclusions confirm the results of investigation, namely, that nothing like precise measures can be expected, and that the impulsions and resistances at the same surface, with the same obliquity of incidence, and the same velocity of motion, are different according to the form and situation of the adjoining parts. Thus the total resistance of a thin board is greater than that of a long prism, having this board for its front or bow, &c.

We are greatly at a loss what to give as absolute measures of these impulsions.

1. With respect to water. The experiments of the French academy on a prism 2 feet broad and deep, and 4 feet long, indicate a resistance of 0.973 pounds avoirdupois to a square foot, moving with the velocity of 1 foot per second at the surface of still water.

Mr Buat's experiments on a square foot wholly immersed in a stream, were as follow:—

A square foot as a thin plate....................1·81 pounds.
„ „ as the front of a box 1 foot long.1·42 „
„ „ as the front of a box 3 feet long.1·29 „
The resistance of sea-water is about $\frac{1}{37}$ greater.

2. With respect to air the varieties are as great. The resistance of a square foot to air moving with the velocity of 1 foot per second, appears from Mr Robin's experiments on 16 square inches to be—

On a square foot	0·001596 pounds.
Chevalier Borda's on 16 inches	0·001757 „
„ „ on 81 inches	0·002042 „
Mr Rouse's on large surfaces	0·002291 „

Precise measures are not to be expected, nor are they necessary in this inquiry. Here we are chiefly interested in their proportions, as they may be varied by their mode of action in the different circumstances of obliquity and velocity.

Direct impulse on the sail perpendicular to the yard.

We begin by recurring to the fundamental proposition concerning the impulse of fluids,—viz., that the absolute pressure is always in a direction perpendicular to the impelled surface, whatever may be the direction of the stream of fluid. We must therefore illustrate the doctrine, by always supposing a flat surface of sail stretched on a yard, which can be braced about in any direction, and giving this sail such a position and such an extent of surface that the impulse on it may be the same, both as to direction and intensity, with that on the real sails. Thus the consideration is greatly simplified. The direction of the impulse is therefore perpendicular to the yard. Its intensity depends on the velocity with which the wind meets the sail, and the obliquity of its stroke. We shall adopt the constructions founded on the common doctrine, that the impulse is as the square of the sine of the inclination, because they are simple; whereas, if we were to introduce the values of the oblique impulses, such as they have been observed in the excellent experiments of the Academy of Paris, the constructions would be complicated in the extreme, and we could hardly draw any consequences which would be intelligible to any but expert mathematicians. The conclusions will be erroneous, not in kind but in quantity only; and we shall point out the necessary corrections, so that the final results will be found not very different from real observation.

A ship compared to an oblong box.

If a ship were a round cylindrical body like a flat tub, floating on its bottom, and fitted with a mast and sail in the centre, she would always sail in a direction perpendicular to the yard. This is evident. But she is an oblong body, and may be compared to a chest, whose length greatly exceeds its breadth. She is so shaped that a moderate force will push her through the water with the head or stern foremost; but it requires a very great force to push her sideways with the same velocity. A fine sailing ship of war will require about twelve times as much force to push her sideways as to push her head foremost. In this respect, therefore, she will very much resemble a chest whose length is twelve times its breadth; and whatever be the proportion of these resistances in different ships, we may always substitute a box, which shall have the same resistances headways and sideways.

Let EFGH (fig. 1) be the horizontal section of such a box, and AB its middle line, and C its centre. In whatever direction this box may chance to move, the direction of the whole resistance on its two sides will pass through C. For as the whole stream has one inclination to the side

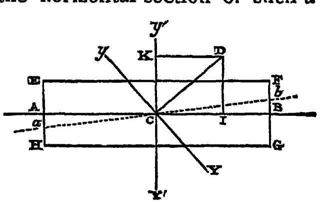

Fig. 1.

EF, the equivalent of the equal impulses on every part will be in a line perpendicular to the middle of EF. For the same reason it will be in a line perpendicular to the middle of FG. These perpendiculars must cross in C. Suppose a mast erected at C, and YC*y* to be a yard hoisted on it carrying a sail. Let the yard be first conceived as braced right athwart at right angles to the keel, as represented by Y'*y*'. Then, whatever be the direction of the wind abaft this sail, it will impel the vessel in the direction CB. But if the sail has the oblique position Y*y*, the impulse will be in the direction CD perpendicular to CY, and will both push the vessel ahead and sideways; for the impulse CD is equivalent to the two impulses CK and CI (the sides of a rectangle of which CD is the diagonal). The force CI pushes the vessel ahead, and CK pushes her sideways. She must therefore take some intermediate direction *ab*, such that the resistance of the water to the plane FG is to its resistance to the plane EF as CI to CK.

Makes lee way when not sailing directly before the wind.

The angle *b*CB between the real course and the direction of the head is called the leeway; and in the course of this dissertation we shall express it by the symbol x. It evidently depends on the shape of the vessel and on the position of the yard. An accurate knowledge of the quantity of leeway, corresponding to different circumstances of obliquity of impulse, extent of surface, &c., is of the utmost importance in the practice of navigation; and even an approximation is valuable. The subject is so very difficult that this must content us for the present.

Let V be the velocity of the ship in the direction C*b*, and let the surfaces FG and FE be called A' and B'. Then the resistance to the lateral motion is $mV^2 \times B' \times \text{sine}^2$, *b*CB, and that to the direct motion is $mV^2 \times A' \times \text{sine}^2$, *b*CK, or $mV^2 \times A' \times \cos^2 b\text{CB}$. Therefore these resistances are in the proportion of $B' \times \text{sine}^2, x$ to $A' \times \cos^2, x$ (representing the angle of leeway *b*CB by the symbol x).

Therefore we have CI : CK, or $\text{CI} : \text{ID} = A' \cdot \cos.^2 x : B' \cdot \text{sine}^2 x, = A' : B' \cdot \frac{\text{sine}^2 x}{\cos.^2 x} = A' : B' \cdot \text{tangent}^2 x.$

How to find the quantity of leeway

Let the angle YCB, to which the yard is braced up, be called the trim of the sails, and expressed by the symbol b. This is the complement of the angle DCI. Now $\text{CI} : \text{ID} = \text{rad.} : \text{tan. DCI}, = 1 : \text{tan. DCI}, = 1 : \text{cotan. } b$. Therefore we have finally $1 : \text{cotan. } b = A' : B' \cdot \tan.^2 x$, and $A' \cdot \text{cotan. } b = B' \cdot \text{tangent}^2 x$, and $\tan.^2 x = \frac{A'}{B'} \text{cot. } b$. This equation evidently ascertains the mutual relation between the trim of the sails and the leeway, in every case where we can tell the proportion between the resistances to the direct and broadside motions of the ship, and where this proportion does not change by the obliquity of the course. Thus, suppose the yard braced up to an angle of 30° with the keel. Then cotan. 30° = 1·732 very nearly. Suppose also that the resistance sideways is twelve times greater than the resistance headways. This gives A = 1 and B' = 12. Therefore $1{\cdot}732 = 12 \times \text{tangent}^2 x$, and $\text{tangent}^2 x = \frac{1{\cdot}732}{12}, = 0{\cdot}14434$, and tan. $x = 0{\cdot}3799$, and $x = 20°, 48'$ very nearly two points of leeway.

This computation, or rather the equation which gives room for it, supposes the resistances proportional to the squares of the sines of incidence. The experiments of the Academy of Paris (see article HYDRODYNAMICS) show that this supposition is not far from the truth when the angle of incidence is great. In the present case the angle of incidence on the front FG is about 70°, and the experiments just now mentioned show that the real resistances exceed the theoretical ones only $\frac{1}{180}$. But the angle of incidence on EF is only 20° 48'. Experiment shows that in this inclination the resistance is almost quadruple of the theoretical resistances. Therefore the lateral resistance is assumed much too small in the present instance. Therefore a much smaller leeway will suffice for producing a lateral resistance which will balance the lateral impulse CK, arising from the obliquity of the sail, viz., 30°. The matter of fact is, that a pretty good sailing ship, with her sails braced to this angle at a medium, will not make above five or six de-

grees leeway in smooth water and fine weather; and yet in this situation the hull and rigging present a very great surface to the wind, in the most improper positions, so as to have a very great effect in increasing her leeway. And if we compute the resistances for this leeway of six degrees by the actual experiments of the French Academy on the angle, we shall find the result not far from the truth,—that is, the direct and lateral resistances will be nearly in the proportion of CI to ID.

It results from this view of the matter, that the leeway is in general much smaller than what the usual theory assigns.

which depends on trim of the sails.

We also see that, according to whatever law the resistances change by a change of inclination, the leeway remains the same while the trim of the sails is the same. The leeway depends only on the direction of the impulse of the wind; and this depends solely on the position of the sails with respect to the keel, whatever may be the direction of the wind. This is a very important observation, and will be frequently referred to in the progress of the present investigation. Note, however, that we are here considering only the action on the sails, and on the same sails. We are not considering the action of the wind on the hull and rigging. This may be very considerable; and it is always in a lee direction, and augments the leeway; and its influence must be so much the more sensible, as it bears a greater proportion to the impulse on the sails. A ship under close-reefed topsails and courses, must make more leeway than when under all her canvas, trimmed to the same angle. But to introduce this additional cause of deviation here would render the investigation too complicated to be of any use.

Illustration of this doctrine by experiments on models and on ships.

This doctrine will be considerably illustrated by attending to the manner in which a lighter is tracked along a canal, or swings to its anchor in a stream. The track-rope is made fast to some staple or bolt E on the deck (fig. 2), and is passed between two of the timber-heads of the bow D, and laid hold of at F on shore.

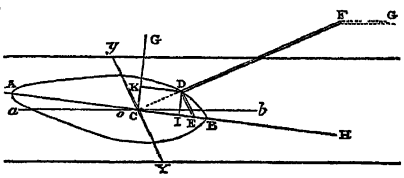

Fig. 2.

The men or cattle walk along the path FG, the rope keeps extended in the direction DF, and the lighter arranges itself in an oblique position AB, and is thus dragged along in the direction *ab*, parallel to the side of the canal; or, if the canal has a current in the opposite direction *ba*, the lighter may be kept steady in its place by the rope DF made fast to a post at F. In this case, it is always observed, that the lighter swings in a position AB, which is oblique to the stream *ab*. Now, the force which retains it in this position, and which precisely balances the action of the stream, is certainly exerted in the direction DF; and the lighter would be held in the same manner if the rope were made fast at C amidship, without any dependence on the timberheads at D; and it would be held in the same position, if, instead of the single rope CF, it were riding by two ropes CG and CH, of which CH is in a direction right ahead, but oblique to the stream, and the other CG is perpendicular to CH or AB. And, drawing DI and DK perpendicular to AB and CG, the strain on the rope CH is to that on the rope CG as CI to CK. The action of the rope in these cases is precisely analogous to that of the sail yY; and the obliquity of the keel to the direction of the motion, or to the direction of the stream, is analogous to the leeway. All this must be evident to any person accustomed to mechanical disquisitions.

A most important use may be made of this illustration. If an accurate model be made of a ship, and if it be placed in a stream of water, and ridden in this manner by a rope made fast at any point D of the bow, it will arrange itself in some determined position AB. There will be a certain obliquity to the stream, measured by the angle B*ob*; and there will be a corresponding obliquity of the rope, measured by the angle FCB. Let yCY be perpendicular to CF. Then CY will be the position of the yard, or trim of the sails corresponding to the leeway bCB. Then, if we shift the rope to a point of the bow distant from D by a small quantity, we shall obtain a new position of the ship, both with respect to the stream and rope; and in this way may be obtained the relation between the position of the sails and the leeway, independent of all theory, and susceptible of great accuracy; and this may be done with a variety of models suited to the most usual forms of ships.

In further thinking on this subject, we are persuaded that these experiments, instead of being made on models, may with equal ease be made on a ship of any size. Let the ship ride in a stream at a mooring D (fig. 3), by means of a short hawser BCD from her bow, having a spring AC on it carried out from her quarter. She will swing to her moorings, till she ranges herself in a certain position AB with respect to the direction *ba* of the stream; and the direction of the hawser DC will point to some point E of the line of the keel.

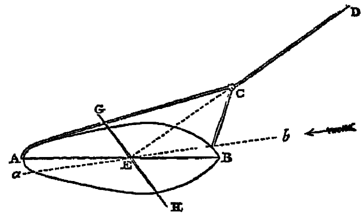

Fig. 3.

Now, it is plain to any person acquainted with mechanical disquisitions, that the deviation BEb is precisely the leeway that the ship will make when the average position of the sails is that of the line GEH perpendicular to ED; at least this will give the leeway which is produced by the sails alone. By heaving on the spring, the knot C may be brought into any other position we please; and for every new position of the knot the ship will take a new position with respect to the stream and to the hawser. And we persist in saying, that more information will be got by this train of experiments than from any mathematical theory: for all the theories of the impulses of fluids must proceed on physical postulates with respect to the motions of the filaments, which are exceedingly conjectural.

The comparison of a ship to an oblong body is only useful to give clear notions on the subject.

And it must now be farther observed, that the substitution which we have made of an oblong parallelopiped for a ship, although well suited to give us clear notions of the subject, is of small use in practice; for it is next to impossible (even granting the theory of oblique impulsions) to make this substitution. A ship is of a form which is not reducible to equations; and therefore the action of the water on her bow or broadside can only be had by a most laborious and intricate calculation for almost every square foot of its surface.[1] And this must be different for every ship. But, which is more unlucky, when we have got a parallelopiped which will have the same proportion of direct and lateral resistance for a particular angle of leeway, it will not answer for another leeway of the same ship; for when the leeway changes, the figure actually exposed to the action of the water changes also. When the leeway is increased, more of the lee-quarter is acted on by the water, and a part of the weather-bow is now removed from its action. Another parallelopiped must therefore be discovered, whose resistances shall suit this new position of the keel with respect to the real course of the ship.

[1] Bezout's *Cours de Mathem.*, vol. v., p. 72, &c.

Seamanship.

We proceed, in the next place, to ascertain the relation between the velocity of the ship and that of the wind, modified as they may be by the trim of the sails and the obliquity of the impulse.

The relation between the velocity of the ship and wind ascertained.

Let AB (figs. 4, 5, and 6) represent the horizontal section of a ship. In place of all the drawing sails—that is, the sails which are really filled—we can always substitute one sail of equal extent, trimmed to the same angle with the keel. This being supposed attached to the yard DCD, let this yard be first of all at right angles to the keel, as represented in fig. 4. Let the wind blow in the direction WC, and let CE (in the direction WC continued) represent the velocity V of the wind. Let CF be the velocity v of the ship. It must also be in the direction of the ship's motion, because when the sail is at right angles to the keel, the absolute impulse on the sail is in the direction of the keel, and there is no lateral impulse, and consequently no leeway. Draw EF, and complete the parallelogram CFEe, producing eC through the centre of the yard to w. Then wC will be the relative or apparent direction of the wind, and Ce or FE will be its apparent or relative velocity. For if the line Ce be carried along CF, keeping always parallel to its first position, and if a particle of air move uniformly along CE (a fixed line in absolute space) in the same time, this particle will always be found in that point of CE, where it is intersected at that instant by the moving line Ce; so that if Ce were a tube, the particle of air, which really moves in the line CE, would always be found in the tube Ce. While CE is the real direction of the wind, Ce will be the position of the vane at the mast-head, which will therefore mark the apparent direction of the wind, or its motion relative to the moving ship.

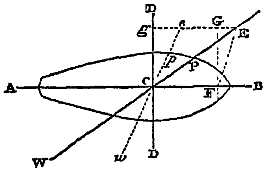

Fig. 4.

We may conceive this in another way. Suppose a cannon-shot fired in the direction CE at the passing ship, and that it passes through the mast at C with the velocity of the wind. It will not pass through the off-side of the ship at P, in the line CE; for while the shot moves from C to P, the point P has gone forward, and the point p is now in the place where P was when the shot passed through the mast. The shot will therefore pass through the ship's side in the point p, and a person on board seeing it pass through C and p, will say that its motion was in the line Cp.

When a ship is in motion, the apparent direction of the wind is always different from the real direction.

Thus it happens, that when a ship is in motion the apparent direction of the wind is always ahead of its real direction. The line wC is always found within the angle WCB. It is easy to see from the construction, that the difference between the real and apparent directions of the wind is so much the more remarkable as the velocity of the ship is greater. For the angle WCw or ECe depends on the magnitude of Ee or CF, in proportion to CE. Persons not much accustomed to attend to these matters are apt to think all attention to this difference to be nothing but affectation of nicety. All seamen are aware that the velocity of a ship has a sensible proportion to that of the wind. "Swift as the wind," is a proverbial expression: but it is one which sometimes indeed falls short of the truth, as it is known, that at times the ship's velocity may exceed that of the wind. The difference between the real direction of the wind and that which in fact impels the ship, namely, its apparent direction, is of great importance when steam propulsion is combined with sails; and will be again noticed when we come to that part of our subject. We may form a pretty exact notion of the velocity of the wind by observing the shadows of the summer clouds flying along the face of a country, and it may be very well measured by this method. The motion of such clouds cannot be very different from that of the air below; and when the pressure of the wind on a flat surface, while blowing with a velocity measured in this way, is compared with its pressure when its velocity is measured by more unexceptionable methods, they are found to agree with all desirable accuracy. Now, observations of this kind frequently repeated, show that what we call a pleasant brisk gale blows at the rate of about ten miles an hour, or about fifteen feet in a second, and exerts a pressure of half a pound on a square foot. Mr Smeaton has frequently observed the sails of a windmill, driven by such a wind, moving faster nay, much faster, towards their extremities, so that the sail, instead of being pressed to the frames on the arms, was taken aback, and fluttering on them. Nay, we know that a good ship, with all her sails set, and the wind on the beam, will, in such a situation, sail above ten knots an hour in smooth water. There is an observation made by every experienced seaman, which shows this difference between the real and apparent directions of the wind very distinctly. When a ship that is sailing briskly with the wind on the beam tacks about, and then sails equally well on the other tack, the wind always appears to have shifted and come more ahead. This is familiar to all seamen. The seaman judges of the direction of the wind by the position of the ship's vanes. Suppose the ship sailing due west on the starboard tack, with the wind apparently N.N.W., the vane pointing S.S.E. If the ship put about, and stands due east on the port tack, the vane will be found no longer to point S.S.E., but perhaps S.S.W., the wind appearing N.N.E., and the ship must be nearly close-hauled in order to make an east course. The wind appears to have shifted four points. If the ship tacks again, the wind returns to its old quarter. We have often observed a greater difference than this. The celebrated astronomer Dr Bradley, taking the amusement of sailing in a pinnace on the river Thames, observed this, and was surprised at it, imagining that the change of the wind was owing to the approaching to or retiring from the shore. The boatmen told him that it always happened at sea, and explained it to him in the best manner they were able. The explanation struck him, and set him a-musing on an astronomical phenomenon which he had been puzzled by for some years, and which he called the aberration of the fixed stars. Every star changes its place a small matter for half a year, and returns to it at the completion of the year. He compared the stream of light from the star to the wind, and the telescope of the astronomer to the ship's vane, while the earth was like the ship, moving in opposite directions when in the opposite point of its orbit. The telescope must always be pointed ahead of the real direction of the star, in the same manner as the vane is always in a direction ahead of the wind; and thus he ascertained the progressive motion of light, and discovered the proportion of its velocity to the velocity of the earth in its orbit, by observing the deviation which was necessarily given to the telescope. Observing that the light shifted its direction about 40″, he concluded its velocity to be about 11,000 times greater than that of the earth; just as the intelligent seaman would conclude from this apparent shifting of the wind, that the velocity of the wind is about triple that of the ship. This is indeed the best method for discovering the velocity of the wind. Let the direction of the vane at the mast-head be very accurately noticed on both tacks, and let the velocity of the ship be also accurately measured. The angle between the directions of the ship's head on these different tacks being halved, will give the real direction of the wind, which must be compared with the position of the vane in order to determine the angle contained between the real and apparent directions of the wind or the angle ECe; or half of the observed shifting of the wind

Observation of Dr Bradley on this subject.

will show the inclination of its true and apparent directions. This being found, the proportion of EC to FC (fig. 6) is easily measured.

We have been very particular on this point, because since the mutual actions of bodies depend on their relative motions only, we should make prodigious mistakes if we estimated the action of the wind by its real direction and velocity, when they differ so much from the relative or apparent.

Velocity of a ship when its sails are at right angles to the keel.

We now resume the investigation of the velocity of the ship (fig. 4), having its sails at right angles to the keel, and the wind blowing in the direction and with the velocity CE, while the ship proceeds in the direction of the keel with the velocity CF. Produce E*e*, which is parallel to BC, till it meet the yard in *g*, and draw FG perpendicular to E*g*. Let *a* represent the angle WCD, contained between the sail and the real direction of the wind, and let *b* be the angle of trim DCB. CE, the velocity of the wind, was expressed by V, and CF, the velocity of the ship, by *v*.

The absolute impulse on the sail is (by the usual theory) proportional to the square of the relative velocity, and to the square of the sine of the angle of incidence; that is, to $FE^2 \times \sin^2 w\mathrm{CD}$. Now the angle $\mathrm{GFE} = w\mathrm{CD}$, and EG is equal to $\mathrm{FE} \times \sin \mathrm{GFE}$; and EG is equal to $\mathrm{E}g - \mathrm{G}g$. But $\mathrm{E}g = \mathrm{EC} \times \sin \mathrm{EC}g, = \mathrm{V} \times \sin a$; and $g\mathrm{G} = \mathrm{CF}, = v$. Therefore $\mathrm{EG} = \mathrm{V} \times \sin a - v$, and the impulse is proportional to $(\mathrm{V} \times \sin a - v)^2$. If S represent the surface of the sail, the impulse, in pounds, will be $n\mathrm{S}\,(\mathrm{V} \times \sin a - v)^2$.

Let A be the surface which, when it meets the water perpendicularly with the velocity *v*, will sustain the same pressure or resistance which the bows of the ship actually meet with. This impulse, in pounds, will be $m\mathrm{A}v^2$. Therefore, because we are considering the ship's motion as in a state of uniformity, the two pressures balance each other; and therefore $m\mathrm{A}v^2 = n\mathrm{S}(\mathrm{V} \times \sin a - v)^2$ and $\frac{m}{n}\mathrm{A}v^2 = \mathrm{S}(\mathrm{V} \times \sin a - v)^2$; therefore $\sqrt{\frac{m}{n}}\sqrt{\mathrm{A}} \times v = \sqrt{\mathrm{S}} \times \mathrm{V} \times \sin a - v\sqrt{\mathrm{S}}$, and $v =$

$$\frac{\sqrt{\mathrm{S}} \times \mathrm{V} \times \sin a}{\sqrt{\frac{m}{n}\mathrm{A}} + \sqrt{\mathrm{S}}} = \frac{\mathrm{V} \times \sin a}{\sqrt{\frac{m\mathrm{A}}{n\mathrm{S}}} + 1} = \frac{\mathrm{V} \times \sin a}{\sqrt{q\frac{\mathrm{A}}{\mathrm{S}}} + 1}.$$

We see, in the first place, that the velocity of the ship is, *cæteris paribus*, proportional to the velocity of the wind, and to the sine of its incidents on the sail jointly; for while the surface of the sail S and the equivalent surface for the bow remains the same, *v* increases or diminishes at the same rate with $\mathrm{V} \cdot \sin.\ a$. When the wind is right astern, the sine of *a* is unity, and then the ship's velocity is $\frac{\mathrm{V}}{\sqrt{\frac{m\mathrm{A}}{n\mathrm{S}}} + 1}$.

Note, that the denominator of this fraction is a common number; for *m* and *n* are numbers and A and S being quantities of one kind, $\frac{\mathrm{A}}{\mathrm{S}}$ is also a number.

It must also be carefully attended to, that S expresses a quantity of sail actually receiving wind with the inclination *a*. It will not always be true, therefore, that the velocity will increase as the wind is more abaft, because some sails will then becalm others. This observation is not, however, of great importance; for it is very unusual to put a ship in the situation considered hitherto; that is, with the yards square, unless she be right before the wind.

If we should discover the relation between the velocity and the quantity of sail in this simple case of the wind right aft, observe that the equation $v = \frac{\mathrm{V}}{\sqrt{\frac{m\mathrm{A}}{n\mathrm{S}}} + 1}$ gives us $\sqrt{\frac{m\mathrm{A}}{n\mathrm{S}}}\,v + v = \mathrm{V}$, and $\sqrt{\frac{m\mathrm{A}}{n\mathrm{S}}}\,v = \mathrm{V} - v$, and $\frac{m\mathrm{A}}{n\mathrm{S}}v^2 = \overline{\mathrm{V} - v}^2$, and $\frac{n\mathrm{S}}{m\mathrm{A}} = \frac{v^2}{(\mathrm{V} - v)^2}$; and because *n* and *m* and A are constant quantities, S is proportional to $\frac{v^2}{(\mathrm{V} - v)^2}$, or the surface of sail is proportional to the square of the ship's velocity directly, and to the square of the relative velocity inversely. Thus, if a ship be sailing with one-eighth of the velocity of the wind, and we would have her sail with one-fourth of it, we must quadruple the sail. This is more easily seen in another way. The velocity of the ship is proportional to the velocity of the wind; and therefore the relative velocity is also proportional to that of the wind, and the impulse of the wind is as the square of the relative velocity. Therefore, in order to increase the relative velocity by an increase of sail only, we must make this increase of sail in the duplicate proportion of the increase of velocity.

Let us, in the next place, consider the motion of a ship whose sails stand oblique to the keel.

Its velocity when the sails stand oblique to the keel.

The construction for this purpose differs a little from the former, because, when the sails are trimmed to any oblique position DCB (figs. 5 and 6), there must be a deviation from the direction of the keel, or a leeway BC*b*. Call this *x*. Let CF be the velocity of the ship. Draw, as before, E*g* perpendicular to the yard, and FG perpendicular to E*g*; also, draw FH perpendicular to the yard; then, as before, EG, which is in the subduplicate ratio of the impulse on the sail, is equal to E*g*—G*g*. Now E*g* is, as before, $= \mathrm{V} \times \sin a$, and G*g* is equal to FH, which is $= \mathrm{CF} \times \sin\ \mathrm{FCH}$, or $= v \times \sin\ (b + x)$. Therefore we have the impulse $= n\mathrm{S}(\mathrm{V} \cdot \sin a - v \cdot \sin\ (b + x))^2$.

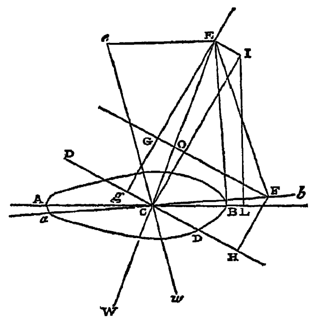

Fig. 5.

This expression of the impulse is perfectly similar to that in the former case, its only difference consisting in the subductive part, which is here $v \times \sin \overline{b + x}$ instead of *v*. But it expresses the same thing as before, viz., the diminution of the impulse. The impulse being reckoned solely in the direction perpendicular to the sail, it is diminished solely by the sail withdrawing itself *in that direction* from the wind; and as *g*E may be considered as the real impulsive motion of the wind, GE must be considered as the relative and effective impulsive motion. The impulse would have been the same had the ship been at rest, and had the wind met it perpendicularly with the velocity GE.

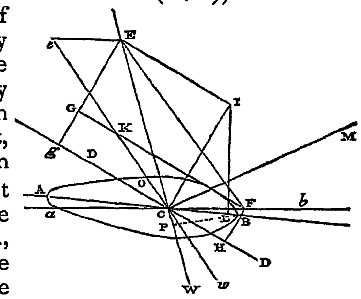

Fig. 6.

Connection between the impulse and motion of the ship.

We must now show the connection between this impulse and the motion of the ship. The sail, and consequently the ship, is pressed by the wind in the direction CI perpendicular to the sail or yard with the force which we have just now determined. This (in the state of uniform motion) must be equal and opposite to the action of the water. Draw IL at right angles to the keel. The impulse in the direction CI (which we may measure by CI) is equivalent to the impulses CL and LI. By the first the ship is impelled right forward, and by the second she is driven side-

ways. Therefore we must have a leeway, and a lateral as well as a direct resistance. We suppose the form of the ship to be known, and therefore the proportion is known, or discoverable, between the direct and lateral resistances corresponding to every angle x of leeway. Let A be the surface whose perpendicular resistance is equal to the direct resistance of the ship corresponding to the leeway x, that is, whose resistance is equal to the resistance really felt by the ship's bows in the direction of the keel when she is sailing with this leeway; and let B in like manner be the surface whose perpendicular resistance is equal to the actual resistance to the ship's motion in the direction LI, perpendicular to the keel. (This is not equivalent to A′ and B′ adapted to the rectangular box, but to $A' \cdot \cos.^2 x$ and $B' \cdot \sin.^2 x$). We have therefore A : B = CL : LI, and $LI = \frac{CL \cdot B}{A}$. Also, because $CI = \sqrt{CL^2 + LI^2}$, we have $A : \sqrt{A^2+B^2} = CL : CI$, and $CI = \frac{CL \cdot \sqrt{A^2+B^2}}{A}$. The resistance in the direction LC is properly measured by $m A v^2$, as has been already observed. Therefore the resistance in the direction IC must be expressed by $m\sqrt{A^2+B^2}|v^2$; or (making C the surface which is equal to $\sqrt{A^2+B^2}$, and which will therefore have the same perpendicular resistance to the water having the velocity v) it may be expressed by mCv^2.

Therefore, because there is an equilibrium between the impulse and resistance, we have $mCv^2 = nS(V \cdot \sin a - v \cdot \sin \overline{b+x})^2$, and $\frac{m}{n} Cv^2$, or $qCv^2 = S(V \cdot \sin a - v \cdot \sin \overline{b+x})^2$ and $\sqrt{q}\sqrt{C}v = \sqrt{S}(V \cdot \sin a - v \cdot \sin \overline{b+x})$.

Therefore $v = \frac{\sqrt{S} \cdot V \cdot \sin a}{\sqrt{q}\sqrt{C} + \sqrt{S} \cdot \sin \overline{b+x}}, = \frac{V \cdot \sin a}{\sqrt{q}\frac{\sqrt{C}}{\sqrt{S}} + \sin \overline{b+x}} = V \frac{\text{Sin } a}{\sqrt{q}\frac{\sqrt{C}}{\sqrt{S}} + \sin \overline{b+x}}$.

Observe that the quantity which is the co-efficient of V in this equation is a common number; for sin. a is a number, being a decimal fraction of the radius 1, $\sin \overline{b+x}$ is also a number, for the same reason. And since m and n were numbers of pounds, $\frac{m}{n}$ or q is a common number. And because C and S are surfaces, or quantities of one kind, $\frac{C}{S}$ is also a common number.

This is the simplest expression that we can think of for the velocity acquired by the ship, though it must be acknowledged to be too complex to be of very prompt use. Its complication arises from the necessity of introducing the leeway x. This affects the whole of the denominator; for the surface C depends on it, because C is $= \sqrt{A^2+B^2}$, and A and B are analogous to $A' \cos {}^2x$ and $B' \sin {}^2x$.

Important consequences deduced from the foregoing theorem.

But we can deduce some important consequences from this theorem.

While the surface S of the sail actually filled by the wind remains the same, and the angle DCB, which in future we shall call the trim of the sails, also remains the same, both the leeway x and the substituted surface C remains the same. The denominator is therefore constant; and the velocity of the ship is proportional to $\sqrt{S} \cdot V \cdot \sin a$; that is, directly as the velocity of the wind, directly as the absolute inclination of the wind to the yard, and directly as the square root of the surface of the sails.

We also learn from the construction of the figure, that FG parallel to the yard cuts CE in a given ratio. For CF is in a constant ratio to Eg, as has been just now demonstrated. And the angle DCF is constant. Therefore CF · sin b, or FH or Gg, is proportional to Eg, and OC to EC, or EC is cut in one proportion, whatever may be the angle ECD, so long as the angle DCF is constant.

We also see that it is very possible for the velocity of the ship on an oblique course to exceed that of the wind. This will be the case when the number $\frac{\sin a}{\sqrt{q\frac{C}{S}} + \sin \overline{b+x}}$ exceeds unity, or when sin a is greater than $\sqrt{q\frac{C}{S}} + \sin \overline{b+x}$. Now this may easily be by sufficiently enlarging S and diminishing $b+x$. It is indeed frequently seen in fine sailers with all their sails set and not hauled too near the wind.

We remarked above that the angle of leeway x affects the whole denominator of the fraction which expresses the velocity. Let it be observed that the angle ICL is the complement of LCD, or of b. Therefore, CL : LI, or A : B = 1 : tan ICL = 1 : cot b, and B = A · cotan b. Now A is equivalent to $A' \cdot \cos^2 x$, and thus b becomes a function of x. C is evidently so, being $\sqrt{A^2+B^2}$. Therefore before the value of this fraction can be obtained, we must be able to compute, by our knowledge of the form of the ship, the value of A for every angle x of leeway. This can be done only by resolving her bows into a great number of elementary planes, and computing the impulses on each and adding them into one sum. The computation is of immense labour, as may be seen by one example given by Bouguer. When the leeway is but small, not exceeding ten degrees, the substitution of the rectangular prism of one determined form is abundantly exact for all leeways contained within this limit; and we shall soon see reason for being contented with this approximation. We may now make use of the formula expressing the velocity for solving the chief problems in this part of the seaman's task.

Problem I. To determine the best position of the sails for standing on a given course, when the direction and velocity of the wind and its angle with the course are given.

And first let it be required to determine the best position of the sail for standing on a given course ab, when CE the direction and velocity of the wind, and its angle with the course WCF, are given. This problem has exercised the talents of the mathematicians ever since the days of Newton. The best plan of solving this problem will be to place the yard CD in such a position that the tangent of the angle FCD may be one half of the tangent of the angle DCW. This will indeed be the best position of the sail for beginning the motion; but as soon as the ship begins to move in the direction CF, the effective impulse of the wind is diminished, and also its inclination to the sail. The angle DCw diminishes continually as the ship accelerates; for CF is now accompanied by its equal eE, and by an angle ECe, or WCw. CF increases, and the impulse on the sail diminishes, till an equilibrium obtains between the resistance of the water and the impulse of the wind. The impulse is now measured by $CE^2 \times \sin^2 eCD$ instead of $CE^2 \times \sin^2 ECD$, that is, by EG^2 instead of Eg^2.

This introduction of the relative motion of the wind renders the actual solution of the problem extremely difficult. It is very easily expressed geometrically: Divide the angle wCF in such a manner that the tangent of DCF may be half of the tangent of DCw, and the problem may be constructed geometrically as follows:—

Let WCF (fig. 7) be the angle between the sail and course. Round the centre C describe the circle WDFY; produce WC to Q, so that $CQ = \frac{1}{3}WC$, and draw QY parallel to CF cutting the circle in Y; bisect the arch WY in D, and draw DC. DC is the proper position of the yard.

Draw the cord WY, cutting CD in V and CF in T; draw the tangent PD, cutting CF in S and CY in R.

It is evident that WY, PR, are both perpendicular to CD, and are bisected in V and D; therefore (by reason of

Seamanship.

the parallels QY, CF) 4 : 3 = QW : CW, = YW : TW, = RP : SP. Therefore PD : PS = 2 : 3, and PD : DS = 2 : 1. Q.E.D. But this division cannot be made to the best advantage till the ship has attained its greatest velocity, and the angle w CF has been produced.

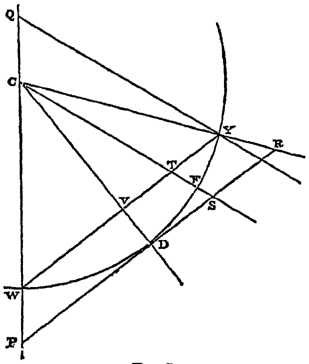

Fig. 7.

We must consider all the three angles, a, b, and x, as variable in the equation which expresses the value of v, and we must make the fluxion of this equation $=0$; then, by means of the equation $B = A \cdot$ cotan b, we must obtain the value of b and of $\dot{b}$ in terms of x and $\dot{x}$. With respect to a, observe, that if we make the angle WCF$=p$, we have $p = a + b + x$; and p being a constant quantity, we have $\dot{a} + \dot{b} + \dot{x} = 0$. Substituting for a, b, $\dot{a}$, and $\dot{b}$, their values in terms of x and $\dot{x}$, in the fluxionary equation $= 0$, we readily obtain x, and then a and b, which solves the problem.

Let it be required, in the next place, to determine the course and the trim of the sails most proper for plying to windward.

Prob. II. To determine the course and trim of the sails most proper for plying to windward.

In fig. 6, draw FP perpendicular to WC. CF is the motion of the ship; but it is only by the motion PC that she gains to windward. Now CP is = CF + cosin WCF, or $v \cdot$ cosin $(a + b + x)$. This must be rendered a maximum, as follows.

By means of the equation which expresses the value of v and the equation $B = A \cdot$ cotan b, we exterminate the quantities v and b; we then take the fluxion of the quantity into which the expression $v \cdot \cos(a + b + x)$ is changed by this operation. Making this fluxion $= 0$, we get the equation which must solve the problem. This equation will contain the two variable quantities a and x with their fluxions; then make the co-efficient of $\dot{x}$ equal to 0, also the co-efficient of $\dot{a}$ equal to 0. This will give two equations, which will determine a and x, and from this we get $b = p - a - x$.

Prob. III. To determine the best course and trim of the sails for getting away from a given line of coast.

Should it be required, in the third place, to find the best course and trim of the sails for getting away from a given line of coast CM (fig. 6), the process perfectly resembles this last, which is in fact getting away from a line of coast which makes a right angle with the wind. Therefore, in place of the angle WCF, we must substitute the angle WCM$\pm$WCF. Call this angle e. We must make $v \cos (e \pm a \pm b \pm x)$ a maximum. The analytical process is the same as the former, only e is here a constant quantity.

Observations on the preceding problems.

These are the three principal problems which can be solved by means of the knowledge that we have obtained of the motion of the ship when impelled by an oblique sail, and therefore making leeway; and they may be considered as an abstract of this part of M. Bouguer's work. We have only pointed out the process for this solution, and have even omitted some things taken notice of by M. Bezout in his very elegant compendium. Our reasons will appear as we go on. The learned reader will readily see the extreme difficulty of the subject, and the immense calculations which are necessary even in the simplest cases, and will grant that it is out of the power of any but an expert analyst to derive any use from them; but the mathematician can calculate tables for the use of the practical seaman. Thus he can calculate the best position of the sails for advancing in a course of 90° from the wind, and the velocity in that course; then for 85°, 80°, 75°, &c. M. Bouguer has given a table of this kind; but to avoid the immense difficulty of the process, he has adapted it to the apparent direction of the wind. We have inserted a few of his numbers, suited to such cases as can be of service, namely, when all the sails draw, or none stand in the way of others. Column 1st is the apparent angle of the wind and course; column 2d is the corresponding angle of the sails and keel; and column 3d is the apparent angle of the sails and wind.

M. Bouguer's table for finding the best position of the sails for advancing in any course.

1 w CF	2 DCB	3 wCD
103°53′	42°30′	61°23′
99 13	40 —	59 13
94 25	37 30	56 55
89 28	35 —	54 28
84 23	32 30	51 53
79 06	30 —	49 06
73 39	27 30	46 09
68 —	25 —	43 —

Inutility of these calculations.

In all these numbers we have the tangent of w CD double of the tangent of DCF. The above table will, we think, be found useful. Column 2 carries the calculation up to 25°, the angle of the yards with the keel; and although some modern ships may go beyond this, and brace their yards up to 23°, we consider 25° a fair average of what can be effected. Certainly the apparent direction of the wind is unknown to the seaman till the ship is sailing with uniform velocity. It is, however, of service to him to know, for instance, that when the angle of the vanes and yards is 56°, the yards should be braced up to 37° 30′. In that case the course would be 94° 25′, from the apparent direction of the wind, that is, with the wind apparently 4° 25′ abaft the beam; a good sailing ship in this position, with the water very smooth and the wind light, may acquire a velocity even exceeding that of the true wind. But the mathematician may require that the yards should be braced up to a smaller angle than is possible.

Let us see whether this restriction in power of bracing up, arising from necessity, leaves anything in our choice, and makes one course preferable to another. We see that there are a prodigious number of courses, and these the most usual and the most important, which we must hold with one trim of the sails; no doubt, sometimes sailing with the wind, even no further forward than the beam, must be performed with this unfavourable trim of the sails, as it must be in all cases if plying to windward. We are certain that the smaller we make the angle of incidence, real or apparent, the smaller will be the velocity of the ship; but it may happen that we shall gain more to windward, or get sooner away from a lee-coast, or any object of danger, by sailing slowly on one course than by sailing quickly on another.

We have seen that while the trim of the sails remains the same, the leeway and the angle of the yard and course remains the same, and that the velocity of the ship is as the sine of the angle of real incidence, that is, as the sine of the angle of the sail and the real direction of the wind.

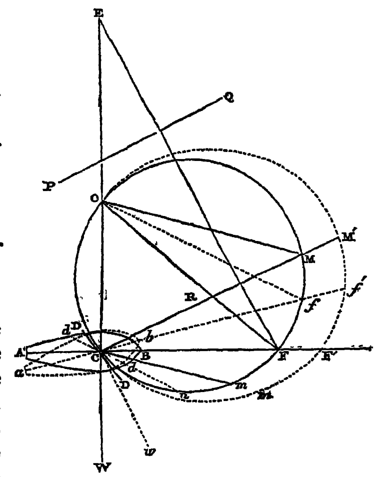

Fig. 8.

Let the ship AB (fig. 8) hold the course CF, with the wind blowing in the direction WC, and having her yards DCD braced up to the smallest angle BCD which the rigging can admit. Let CF be to CE as the velocity of the

Seamanship.

ship to the velocity of the wind; join FE and draw Cw parallel to EF; it is evident that FE is the relative motion of the wind, and wCD is the relative incidence on the sail.

Draw FO parallel to the yard DC, and describe a circle through the points COF; then we say that if the ship, with the same wind and the same trim of the same drawing sails, be made to sail on any other course Cf, her velocity along CF is to the velocity along Cf as CF is to Cf; or, in other words, the ship will employ the same time in going from C to any point of the circumference CFO.

Join fO. Then, because the angles CFO, CfO are on the same cord CO, they are equal, and fO is parallel to dCd, the new position of the yard corresponding to the new position of the keel ab, making the angle dCb=DCB. Also, by the nature of the circle, the line CF is to Cf as the sine of the angle CFO to the sine of the angle COf, that is (on account of the parallels CD, OF and Cd, Of), as the sine of WCD to the sine of WCd. But when the trim of the sails remains the same, the velocity of the ship is as the sine of the angle of the sail with the direction of the wind; therefore CF is to Cf as the velocity on CF to that on Cf, and the proposition is demonstrated.

To determine the best course for avoiding a rock.

Let it now be required to determine the best course for avoiding a rock R lying in the direction CR, or for withdrawing as fast as possible from a line of coast PQ. Draw CM through R, or parallel to PQ, and let m be the middle of the arch CmM. It is plain that m is the most remote from CM of any point of the arch CmM, and therefore the ship will recede farther from the coast PQ in any given time, by holding the course Cm than by any other course.

This course is easily determined; for the arch CmM $=360°$—(arch CO + arch OM), and the arch CO is the measure of twice the angle CFO, or twice the angle DCB, or twice $\overline{b+x}$, and the arch OM measures twice the angle ECM.

Thus, suppose the sharpest possible trim of the sails to be 35°, and the observed angle ECM to be 70°; then CO + OM is 70° + 140° or 210°. This being taken from 360°, leaves 150°, of which the half Mm is 75°, and the angle MCm is 37° 30′. This added to ECM makes ECm 170° 30′, leaving WCm=72° 30′, and the ship must hold a course making an angle of 72° 30′ with the real direction of the wind, and WCD will be 37° 30′.

This supposes no leeway. But if we know that under all the sail which the ship can carry with safety and advantage she makes 5 degrees of leeway, the angle DCm of the sail and course, or $b+x$, is 40°. Then CO + OM = 220°, which being taken from 360°, leaves 140°, of which the half is 70°, = Mm, and the angle MCm = 35°, and ECm = 105, and WCm = 75°, and the ship must lie with her head 70° from the wind, making 5 degrees of leeway, and the angle WCD is 35°.

The general rule for the position of the ship is, *that the line on shipboard which bisects the angle* b + x *may also bisect the angle* WCM, or make the angle between the course and the line, from which we wish to withdraw, equal to the angle between the sail and the real direction of the wind.

Corollaries.

It is plain that this problem includes that of plying to windward. We have only to suppose ECM to be 90°; then, taking our example in the same ship, with the same trim and the same leeway, we have $b+x=40°$. This taken from 90° leaves 50°, and WCn = 90—25 = 65, and the ship's head must lie 60° from the wind, and the yard must be 25° from it.

It must be observed here, that it is not always eligible to select the course which will remove the ship fastest from the given line CM; it may be more prudent to remove from it more securely though more slowly. In such cases the procedure is very simple, viz., to shape the course as near the wind as is possible.

The reader will also easily see that the propriety of these practices is confined to those courses only where the practicable trim of the sails is not sufficiently sharp. Whenever the course lies so far from the wind that it is possible to make the tangent of the apparent angle of the wind and sail double the tangent of the sail and course, it should be done.

The adjustment of the sails supposed in the theory impracticable.

These are the chief practical consequences which can be deduced from the theory. But we should consider how far this adjustment of the sails and course can be performed. And here occur difficulties so great as to make it almost impracticable. We have always supposed the position of the surface of the sail to be distinctly observable and measurable; but this can be hardly affirmed even with respect to a sail stretched on a yard. Here we supposed the surface of the sail to have the same inclination to the keel that the yard has. This is by no means the case; the sail assumes a concave form, of which it is almost impossible to assign the direction of the mean impulse. We believe that this is always considerably to leeward of a perpendicular to the yard, lying between CI and CE (fig. 6). This is of some advantage, being equivalent to a sharper trim. We cannot affirm this, however, with any confidence, because it renders the impulse on the weather-leech of the sail so exceedingly feeble as hardly to have any effect. In sailing close to the wind, the ship is kept so near that the weather-leech of the sail is almost ready to receive the wind edgewise, and to flutter or shiver. The most effective or drawing sails with a side-wind, especially when plying to windward, are the trysails. We believe that it is impossible to say, with anything approaching to precision, what is the position of the general surface of a staysail, or to calculate the intensity and direction of the general impulse; and we affirm with confidence that no man can pronounce on these points with any exactness. If we can guess within a third or a fourth part of the truth, it is all we can pretend to; and after all, it is but a guess. Add to this, the sails coming in the way of each other, and either becalming them or sending the wind upon them in a direction widely different from that of its free motion. All these points we think beyond our power of calculation, and therefore that it is in vain to give the seaman mathematical rules, or even tables of adjustment ready calculated; since he can neither produce that medium position of his sails that is required, nor tell what is the position which he employs.

This is one of the principal reasons why so little advantage has been derived from the very ingenious and promising disquisitions of Bouguer and other mathematicians.

We subjoin an abstract of the experiments made by the Royal Academy of Sciences at Paris. Column 1st gives the angle of incidence; column 2d gives the impulsions really observed; column 3d the impulses, had they followed the duplicate ratio of the sines; and column 4th the impulses, if they were in the simple ratio of the sines.

Angle of incid.	Impulsion observed.	Impulse as sine.^{2}	Impulse as sine.

Seamanship.

The theory erroneous, and the deductions useless.

Here we see an enormous difference in the great obliquities. When the angle of incidence is only six degrees, the observed impulse is forty times greater than the theoretical impulse; at 12° it is ten times greater; at 18° it is more than four times greater; and at 24° it is almost three times greater.

No wonder then that the deductions from this theory are so useless and so unlike what we familiarly observe. We took notice of this when we were considering the leeway of a rectangular box, and thus saw a reason for admitting an incomparably smaller leeway than what would result from the laborious computations necessary by the theory. This error in theory has as great an influence on the impulsions of air when acting obliquely on a sail; and the experiments of Mr Robins and of the Chevalier Borda, on the oblique impulsions of air, are perfectly conformable (as far as they go) to those of the academicians on water. The oblique impulsions of the wind are therefore much more efficacious for pressing the ship in the direction of her course than the theory allows us to suppose; and the progress of a ship plying to windward is much greater, both because the oblique impulses of the wind are more effective, and because the leeway is much smaller, than we suppose. Were not this the case, it would be impossible for a square-rigged ship to get to windward. The impulse on her sails, when close hauled, would be so trifling, that she would not have a third part of the velocity which we see her acquire: and this trifling velocity would be wasted in leeway; for we have seen that the diminution of the oblique impulses of the water is accompanied by an increase of leeway. But we see that in the great obliquities the impulsions continue to be very considerable, and that even an incidence of 6° gives an impulse as great as the theory allows to an incidence of 40°. We may, therefore, on all occasions keep the yards more square; and the loss which we sustain by the diminution of the very oblique impulse will be more than compensated by its more favourable direction with respect to the ship's keel. Let us take an example of this. Suppose the wind about two points before the beam, making an angle of 68° with the keel. The theory assigns 43° for the inclination of the wind to the sail, and 15° for the trim of the sail. The perpendicular impulse being supposed 1000, the theoretical impulse for 45° is 465. This reduced in the proportion of radius to the sine of 25°, gives the impulse in the direction of the course only 197.

But if we ease off the lee-braces till the yard makes an angle of 50° with the keel, and allows the wind an incidence of no more than 18°, we have the experimented impulse 414, which, when reduced in the proportion of radius to the sine of 50°, gives an effective impulse 317. In like manner, the trim 56°, with the incidence 12°, gives an effective impulse 337; and the trim of 62°, with the incidence only 6°, gives 353.

Hence it would at first sight appear that the angle DCB of 62° and WCD of 6° would be better for holding a course within six points of the wind than any more oblique position of the sails; but it will only give a greater initial impulse. As the ship accelerates, the wind apparently comes ahead, and we must continue to brace up as a ship freshens her way. It is not unusual for her to acquire half or two-thirds of the velocity of the wind; in which case the wind comes apparently ahead more than two points, when the yards must be braced up to 35°, and thus allows an impulse no greater than about 7°. Now, this is very frequently observed in good ships, which, in a brisk gale and smooth water, will go five or six knots close-hauled, the ship's head six points from the wind, and the sails no more than just full, but ready to shiver by the smallest luff. All this would be impossible by the usual theory; and in this respect these experiments of the French Academy give a fine illustration of the seaman's practice. They account for what we should otherwise be much puzzled to explain; and the great progress which is made by a ship close-hauled being perfectly agreeable to what we should expect from the law of oblique impulsions, deducible from these so often-mentioned experiments, while it is totally incompatible with the common theory, should make us abandon the theory without hesitation, and strenuously set about the establishment of another, founded entirely on experiments.

Experiments proper for establishing another.

For this purpose the experiments should be made on the oblique impulsions of air, on as great a scale as possible, and in as great a variety of circumstances, so as to furnish a series of impulsions for all angles of obliquity. We have but four or five experiments on this subject, viz., two by Mr Robins, and two or three by the Chevalier Borda. Having thus gotten a series of impulsions, it is very practicable to raise on this foundation a practical institute, and to give a table of the velocities of a ship suited to every angle of inclination and of trim; for nothing is more certain than the resolution of the impulse perpendicular to the sail into a force in the direction of the keel, and a lateral force.

We are also disposed to think that experiments might be made on a model very nicely rigged with sails, and trimmed in every different degree, which would point out the mean direction of the impulse on the sails, and the comparative force of these impulses on different directions of the wind. The method would be very similar to that for examining the impulse of the water on the hull. If this can also be ascertained experimentally, the intelligent reader will easily see that the whole motion of a ship under sail may be determined for every case. Tables may then be constructed by calculation, or by graphical operations, which will give the velocities of a ship in every different course, and corresponding to every trim of sail. And let it be here observed, that the trim of the sail is not to be estimated in degrees of inclination of the yards; because, as we have already remarked, we cannot observe nor adjust the fore and aft sails in this way. But, in making the experiments for ascertaining the impulse, the exact position of the tacks and sheets of the sails are to be noted; and this combination of adjustments is to pass by the name of a certain trim. Thus that trim of all the sails may be called 40, whose direction is experimentally found equivalent to a flat surface trimmed to the obliquity 40°.

Having done this, we may construct a figure for each trim similar to fig. 8, where, instead of a circle, we shall have a curve COM'F', whose cords CF', cf', &c., are proportional to the velocities in these courses; and by means of this curve we can find the point m', which is most remote from any line CM from which we wish to withdraw; and thus we may solve all the principal problems of the art.

We hope that it will not be accounted presumption in us to expect more improvement from a theory founded on judicious experiments only, than from a theory of the impulse of fluids, which is found so inconsistent with observation, and of whose fallacy all its authors, from Newton to D'Alembert, entertained strong suspicions.

With those observations we conclude our discussion of the first part of the seaman's task, and now proceed to consider the means that are employed to prevent or to produce any deviations from the uniform rectilineal course which has been selected.

Means employed to prevent or produce deviations from a course.

Here the ship is to be considered as a body in free space, convertible round her centre of inertia. For whatever may be the point round which she turns, this motion may always be considered as compounded of a rotation round an axis passing through her centre of gravity or inertia. She is impelled by the wind and by the water acting on many surfaces differently inclined to each other, and the impulse on each is perpendicular to the surface. In order, therefore, that she may continue steadily in one course, it is not only necessary that the impelling forces, estimated in their

mean direction, be equal and opposite to the resisting forces estimated in their mean direction; but also that these two directions may pass through one point, otherwise she will be affected as a log of wood is when pushed in opposite directions by two forces, which are equal indeed, but are applied to different parts of the log. A ship must be considered as a lever, acted on in different parts by forces in different directions, and the whole balancing each other round that point or axis where the equivalent of all the resisting forces passes. This may be considered as a point supported by this resisting force and as a sort of fulcrum; therefore, in order that the ship may maintain her position, the energies or *momenta* of all the impelling forces round this point must balance each other.

Impulses on a ship sailing right before the wind different from those on her when sailing obliquely.

When a ship sails right afore the wind, with her yards square, it is evident that the impulses on each side of the keel are equal, as also their mechanical *momenta* round any axis passing perpendicularly through the keel. So are the actions of the water on her bows. But when she sails on an oblique course, with her yards braced on either side, she sustains a pressure in the direction CI (fig. 5) perpendicular to the sail. This, by giving her a lateral pressure LI, as well as a pressure CL ahead, causes her to make leeway, and to move in a line C*b* inclined to CB. By this means the balance of action on the two bows is destroyed, the general impulse on the lee-bow is increased, and that on the weather-bow is diminished. The combined impulse is therefore no longer in the direction BC, but (in the state of uniform motion) in the direction IC.

Suppose that in an instant the whole sails are annihilated and the impelling pressure CI, which precisely balanced the resisting pressure on her bows, removed. The ship tends, by her inertia, to proceed in the direction C*b*. This tendency produces a continuation of the resistance in the opposite direction IC, which is not directly opposed to the tendency of the ship in the direction C*b*; therefore the ship's head would immediately come up to the wind. The experienced seaman will recollect something like this when the sails are suddenly lowered when coming to anchor. It does not happen solely from the obliquity of the action on the bows. It would happen to the parallelopiped of fig. 2, which was sustaining a lateral impulsion $B\cdot\sin^2 x$, and a direct impulsion $A\cdot\cos^2 x$. These are continued for a moment after the annihilation of the sail; but being no longer opposed by a force in the direction CD, but by a force in the direction C*b*, the force $B\cdot\sin^2 x$ must prevail, and the body is not only retarded in its motion, but its head turns towards the wind. But this effect of the leeway is greatly increased by the curved form of the ship's bows. This occasions the centre of effort of all the impulsions of the water on the leeside of the ship to be very far forward, and this so much the more remarkably as she is sharper afore. It is in general not much abaft the foremast. Now the centre of the ship's tendency to continue her motion is the same with her centre of gravity, and this is generally but a little before the mainmast. She is therefore in the same condition nearly as if she were pushed at the mainmast in a direction parallel to C*b*, and at the foremast by a force parallel to IC. The evident consequence of this is a tendency to come up to the wind. This is independent of all situation of the sails, provided only that they have been trimmed obliquely.

In the generality of ships sailing in smooth water, there is a tendency in their heads to approach the wind, which must be counteracted by keeping the helm a little a-weather. This tendency is greatest in ships that are sharp forward. This circumstance is easily understood. Whatever is the direction of the ship's motion, the absolute impulse on that part of the bow immediately contiguous to B is perpendicular to that very part of the surface. The more acute, therefore, that the angle of the bow is, the more will the impulse on that part be perpendicular to the keel, and the greater will be its energy to turn the head to windward.

Propriety of the disposition of the sails of a ship.

Thus we are enabled to understand or to see the propriety of the disposition of the sails of a ship. We see her crowded with sails forward, and even many sails extended far before her bow, such as the fore-topmast staysail, the jib, and flying jib. The sails abaft are comparatively smaller. The sails on the mizenmast are much smaller than those on the foremast. All the staysails hoisted on the mainmast may be considered as headsails, because their centres of effort are considerably before the centre of gravity of the ship; and notwithstanding this disposition, it generally requires a small action of the rudder to counteract the windward tendency of the lee-bow. This is considered as a good quality when moderate, because it enables the seaman to throw the sails aback, and stop the ship's way in a moment, if she be in danger from anything ahead; and the ship which does not carry a little of a weather helm is always a dull sailer.

Action of the water and the sails.

In order to judge somewhat more accurately of the action of the water and sails, suppose the ship AB (fig. 9) to have its sails on the mizenmast D, the mainmast E, and the foremast F, braced up or trimmed alike, and the three lines D *i*, E *e*, F *f*, perpendicular to the sails, are in the proportion of the impulses on the sails. The ship is driven ahead and to leeward, and moves in the path *a*C*b*. This path is so inclined to the line of the keel, that the medium direction of the resistance of the water is parallel to the direction of the impulse. A line CI may be drawn parallel to the lines D *i*, E *e*, F *f*, and equal to their sum; and it may be drawn from such a point C, that the actions on all the parts of the hull between C and B may balance the *momenta* of all the actions on the hull between C and A. This point may justly be called the *centre of effort*, or the *centre of resistance*. We cannot determine this point for want of a proper theory of the resistance of fluids. Nay, although experiments like those of the Parisian Academy should give us the most perfect knowledge of the intensity of the oblique impulses on a square foot, we should hardly be benefited by them; for the action of the water on a square foot of the hull at *p*, for instance, is so modified by the intervention of the stream of water which has struck the hull about B, and glided along the bow B *o p*, that the pressure on *p* is totally different from what it would have been were it a square foot or surface detached from the rest, and presented in the same position to the water moving in the direction *b*C. For it is found, that the resistances given to planes joined so as to form a wedge, or to curved surfaces, are widely different from the accumulated resistances calculated for their separate parts, agreeably to the experiments of the academy on single surfaces. We therefore do not attempt to ascertain the point C by theory; but it may be accurately determined by the experiments which we have so strongly recommended, and we offer this as an additional inducement for prosecuting them.

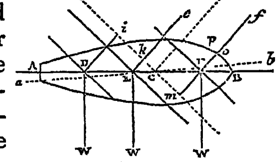

Fig. 9.

Centre of effort.

To be determined by experiments.

Draw through C a line perpendicular to CI, that is, parallel to the sails; and let the lines of impulse of the three sails cut in the points *i*, *k*, and *m*. This line *i m* may be considered as a lever, moveable round C, and acted on at the points *i*, *k*, and *m*, by three forces. The rotatory momentum of the sails on the mizenmast is $D\,i \times i\,C$; that of the sails on the mainmast is $E\,e \times k\,C$; and the momentum of the sails on the foremast is $F\,f \times m\,C$. The two first tend to press forward the arm C *i*, and then to turn the ship's head towards the wind. The action of the sails on the foremast tends to pull the arm C *m* forward, and produce a

contrary rotation. If the ship under these three sails keeps steadily in her course, without the aid of the rudder, we must have $Di \times iC + Ee \times kC = Ff \times mC$. This is very possible, and is often seen in a ship under her mizen-topsail, main-topsail, and fore-topsail, all parallel to one another, and their surfaces duly proportioned by reefing. If more sails are set, we must always have a similar equilibrium. A certain number of them will have their efforts directed from the larboard arm of the lever *i m* lying to leeward of CI, and a certain number will have their efforts directed from the starboard arm lying to windward of CI. The sum of the products of each of the first set, by their distances from C, must be equal to the sum of the similar products of the other set. As this equilibrium is all that is necessary for preserving the ship's position, and the cessation of it is immediately followed by a conversion; and as these states of the ship may be had by means of the three square sails only, when their surfaces are properly proportioned, it is plain that every movement may be executed and explained by their means. This will greatly simplify our future discussions. We shall therefore suppose in future that there are only the three topsails set, and that their surfaces are so adjusted by reefing, that their actions exactly balance each other round that point C of the middle line AB, where the actions of the water on the different parts of the ship's bottom in like manner balance each other. This point C may be differently situated in the ship according to the leeway she makes, depending on the trim of the sails; and, therefore, although a certain proportion of the three surfaces may balance each other in one state of leeway, they may happen not to do so in another state. But the equilibrium is evidently attainable in every case, and we therefore shall always suppose it.

Equilibrium preserved by the position of the sails.

Consequence of destroying it.

It must now be observed, that when this equilibrium is destroyed, as, for example, by turning the edge of the mizen-topsail to the wind, which the seamen call *shivering* the mizen-topsail, and which may be considered as equivalent to the removing the mizen-topsail entirely, it does not follow that the ship will turn round the point C, this point remaining fixed. The ship must be considered as a free body, still acted on by a number of forces, which no longer balance each other; and she must therefore *begin* to turn round a spontaneous axis of conversion, which must be determined in the way set forth in the article ROTATION. It is of importance to point out in general where this axis is situated. Therefore let G (fig. 10) be the centre of gravity of the ship. Draw the line q G v parallel to the yards, cutting D d in q, Ee in r, CI in t, and Ff in v. While the three sails are set, the line $q\,v$ may be considered as a lever acted on by four forces, viz., Dd, impelling the lever forward perpendicularly in the point q; Ee, impelling it forward in the point r; Ff, impelling it forward in the point v; and CI, impelling it backward in the point t. These forces balance each other both in respect of progressive motion and of rotatory energy; for CI was taken equal to the sum of Dd, Ee, and Ff; so that no acceleration or retardation of the ship's progress in her course is supposed.

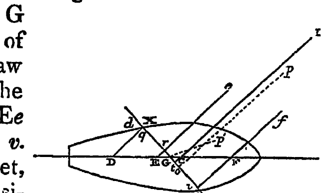

Fig. 10.

But by taking away the mizen-topsail, both the equilibriums are destroyed. A part Dd of the accelerating force is taken away; and yet the ship, by her inertia or inherent force, tends, for a moment, to proceed in the direction Cp with her former velocity: and by this tendency exerts for a moment the same pressure CI on the water, and sustains the same resistance IC. She must therefore be retarded in her motion by the excess of the resistance IC over the remaining impelling forces Ee and Ff; that is, by a force equal and opposite to Dd. She will therefore be retarded in the same manner as if the mizen-topsail were still set, and a force equal and opposite to its action were applied to G, the centre of gravity, and she would soon acquire a smaller velocity, which would again bring all things into equilibrium; and she would stand on in the same course, without changing either her leeway or the position of her head.

But the equilibrium of the lever is also destroyed. It is now acted on by three forces only, viz., Ee and Ff, impelling it forward in the points r and v, and IC impelling it backward in the point t. Make $rv : ro = \text{E}e + \text{F}f : \text{F}f$, and make $o\,p$ parallel to CI and equal to Ee + Ff. Then we know, from the common principles of mechanics, that the force $o\,p$ acting at o will have the same momentum or energy to turn the lever round *any* point whatever as the two forces Ee and Ff applied at r and v; and now the lever is acted on by two forces, viz., IC, urging it backwards in the point t, and $o\,p$ urging it forwards in the point o. It must therefore turn round like a floating log, which gets two blows in opposite directions. If we now make $\text{IC}-op : op = to : tx$, or $\text{IC}-op : \text{IC} = to : ox$, and apply to the point x a force equal to IC—$o\,p$ in the direction IC; we know by the common principles of mechanics, that this force IC—$o\,p$ will produce the same rotation round any point as the two forces IC and $o\,p$ applied in their proper directions at t and o. Let us examine the situation of the point x.

The force IC—$o\,p$ is evidently = D d, and $o\,p$ is = Ee + Ff. Therefore $ot : tx = \text{D}d : op$. But because, when all the sails were filled, there was an equilibrium round C, and therefore round t, and because the force $o\,p$ acting at o is equivalent to E e and F f acting at r and v, we must still have the equilibrium; and therefore we have the momentum $\text{D}d \times qt = op \times ot$. Therefore $ot : tq = \text{D}d : op$, and $tq = tx$. Therefore the point x is the same with the point q.

By shivering the mizen-topsail.

Therefore, when we shiver the mizen-topsail, the rotation of the ship is the same as if the ship were at rest, and if a force equal and opposite to the action of the mizen-topsail were applied at q or at D, or any point on the line D q.

This might have been shown in another and shorter way. Suppose all sails filled, the ship is in equilibrio. This will be disturbed by applying to D a force opposite to D d; and if the force be also equal to D d, it is evident that these two forces destroy each other, and that this application of the force d D is equivalent to the taking away of the mizen-topsail. But we chose to give the whole mechanical investigation; because it gave us an opportunity of pointing out to the reader, in a case of very easy comprehension, the precise manner in which the ship is acted on by the different sails and by the water, and what share each of them has in the motion ultimately produced. We shall not repeat this manner of procedure in other cases, because a little reflection on the part of the reader will now enable him to trace the *modus operandi* through all its steps.

We now see that, in respect both of progressive motion and of conversion, the ship is affected by shivering the sail D, in the same manner as if a force equal and opposite to D d were applied at D, or at any point in the line D d.

Let p represent a particle of matter, r its radius vector, or its distance p G from an axis passing through the centre of gravity G, and let M represent the whole quantity of matter of the ship. Then its momentum of inertia is $= \int p\,r^2$. The ship, impelled in the point D by a force in the direction dD, will begin to turn round a spontaneous vertical axis, passing through a point S of the line q G, which is drawn through the centre of gravity G, perpendicular to the direction dD of the external force, and the distance GS of this axis from the centre of gravity is $= \dfrac{\int p\,r^2}{\text{M}\cdot\text{G}q}$, and it is taken on the opposite side of G from q, that is, S and q are on opposite sides of G.

Let us express the external force by the symbol F. It is equivalent to a certain number of pounds, being the pressure of the wind moving with the velocity V and inclination a on the surface of the sail D; and may therefore be computed either by the theoretical or experimental law of oblique impulses. Having obtained this, we can ascertain the angular velocity of the rotation and the absolute velocity of any given point of the ship by means of the theorems established in the article ROTATION.

Action of the rudder.

But before we proceed to this investigation, we shall consider the action of the rudder, which operates precisely in the same manner. Let the ship AB (fig. 11) have her rudder in the position AD, the helm being hard a-starboard, while the ship sailing on the starboard tack, and making leeway, keeps on the course ab. The lee surface of the rudder meets the water obliquely. The very foot of the rudder meets it in the direction DE parallel to $a\,b$. The parts farther up meet it with various obliquities, and with various velocities, as it glides round the bottom of the ship and falls into the wake. It is absolutely impossible to calculate the accumulated impulse. We shall not be far mistaken in the deflection of each contiguous filament, as it quits the bottom and glides along the rudder; but we neither know the velocity of these filaments, nor the deflection and velocity of the filaments gliding without them. We therefore imagine that all computations on the subject are in vain. But it is enough for our purpose that we know the direction of the absolute pressure which they exert on its surface. It is in the direction D d, perpendicular to that surface. We also may be confident that this pressure is very considerable, in proportion to the action of the water on the ship's bows, or of the wind on the sails; and we may suppose it to be nearly in the proportion of the square of the velocity of the ship in her course; but we cannot affirm it to be accurately in that proportion, for reasons that will readily occur to one who considers the way in which the water falls in behind the ship.

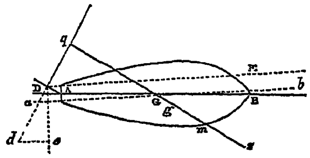

Fig. 11.

Greatest in a fine sailer.

It is observed, however, that a fine sailer always steers well, and that all movements by means of the rudder are performed with great rapidity when the velocity of the ship is great. We shall see by and by, that the speed with which the ship performs the angular movements is in the proportion of her progressive velocity: for we shall see that the squares of the times of performing the revolution are as the impulses inversely, which are as the squares of the velocities. There is perhaps no force which acts on a ship that can be more accurately determined by experiment than this. Let the ship ride in a stream or tideway whose velocity is accurately measured; and let her ride from two moorings, so that her bow may be a fixed point. Let a small tow line be laid out from her stern or quarter at right angles to the keel, and connected with some apparatus fitted up on shore or on board another ship, by which the strain on it may be accurately measured; a person conversant with mechanics will see many ways in which this can be done. Perhaps the following may be as good as any: let the end of the tow-line be fixed to some point as high out of the water as the point of the ship from which it is given out, and let this be very high. Let a block with a hook be on the rope, and a considerable weight hung on this hook. Things being thus prepared, put down the helm to a certain angle, so as to cause the ship to sheer off from the point to which the far end of the tow-line is attached. This will stretch the rope, and raise the weight out of the water. Now heave upon the rope, to bring the ship back again to her former position, with her keel in the direction of the stream. When this position is attained, note carefully the form of the rope, that is, the angle which its two parts make with the horizon. Call this angle a. Every person acquainted with these subjects knows that the horizontal strain is equal to half the weight multiplied by the cotangent of a, or that 2 is to the cotangent of a as the weight to the horizontal strain. Now it is this strain which balances, and therefore measures the action of the rudder, or D e in fig. 11. Therefore, to have the absolute impulse D d, we must increase D e in the proportion of radius to the secant of the angle b, which the rudder makes with the keel. In a great ship sailing six miles in an hour, the impulse on the rudder inclined 30° to the keel is not less than 3000 pounds. The surface of the rudder of such a ship contains nearly 80 square feet. It is not, however, very necessary to know this absolute impulse Dd, because it is its parts D e alone which measure the energy of the rudder in producing a conversion. Such experiments, made with various positions of the rudder, will give its energies corresponding to these positions, and will settle that long disputed point, which is the best position for turning a ship. On the hypothesis that the impulsions of fluids are in the duplicate ratio of the sines of incidence, there can be no doubt that it should make an angle of 54° 44′ with the keel, being about the angle with the keel that the rudder can be put over in modern ships; the angle of maximum effect assigned by theory.

How to determine it.

Why a ship misses stays, &c.

A ship misses stays in rough weather for want of a sufficient progressive velocity, and because her bows are beat off by the waves; and there is seldom any difficulty in wearing the ship, if she has any progressive motion. It is, however, always desirable to give the rudder as much influence as possible. Its surface should be enlarged (especially below) as much as can be done consistently with its strength, and with the power of the steersman to manage it; and it should be put in the most favourable situation for the water to get at it with great velocity; and it should be placed as far from the axis of the ship's motion as possible. In order to ascertain the motion produced by the action of the rudder, draw from the centre of gravity a line G q perpendicular to Dd (Dd being drawn through the centre of effort of the rudder). Then, as in the consideration of the action of the sails, we may conceive the line qG as a lever connected with the ship, and impelled by a force Dd acting perpendicularly at q. The consequence of this will be, an incipient conversion of the ship about a vertical axis passing through some point S in the line qG, lying on the other side of G from q; and we have, as in the former case,

$$GS = \frac{\int p \cdot r^2}{M \cdot Gq}.$$

The action of the rudder similar to that of the sails, and very great.

Thus the action and effects of the sails and of the rudder are perfectly similar, and are to be considered in the same manner. We see that the action of the rudder, though of a small surface in comparison of the sails, must be very great: for the impulse of water is many hundred times greater than that of the wind; and the arm qG of the lever, by which it acts, is incomparably greater than that by which any of the impulsions on the sails produces its effect; accordingly, the ship yields much more rapidly to its action than she does to the lateral impulse of a sail.

Observe here, that if G were a fixed or supported axis, it would be the same thing whether the absolute force Dd of the rudder acts in the direction Dd, or its transverse parts De act in the direction De, both would produce the same rotation; but it is not so in a free body. The force Dd both tends to retard the ship's motion and to produce a rotation: it retards it as much as if the same force Dd had been immediately applied to the centre. And thus the real motion of the ship is compounded of a motion of the centre in a direction parallel to Dd, and of a motion round the centre. These two constitute the motion round S.

As the effects of the action of the rudder are both more

Seamanship.

Employed as an example of the motions of conversion.

remarkable and somewhat more simple than those of the sails, we shall employ them as an example of the mechanism of the motions of conversion in general; and as we must content ourselves, in a work like this, with what is very general, we shall simplify the investigation by attending only to the motion of conversion. We can get an accurate notion of the whole motion, if wanted for any purpose, by combining the progressive or retrograde motion parallel to Dd with the motion of rotation which we are about to determine.

In this case, then, we observe, in the first place, that the angular velocity is $\frac{Dh \cdot qG}{\int pr^2}$; and, as was shown in ROTATION, this velocity of rotation increases in the proportion of the time of the forces' uniform action, and the rotation would be uniformly accelerated if the forces did really act uniformly. This, however, cannot be the case, because, by the ship's change of position and change of progressive velocity, the direction and intensity of the impelling force is continually changing. But if two ships are performing similar evolutions, it is obvious that the changes of force are similar in similar parts of the evolution. Therefore the consideration of the momentary evolution is sufficient for enabling us to compare the motions of ships actuated by similar forces, which is all we have in view at present. The velocity v, generated in any time t by the continuance of an invariable momentary acceleration (which is all that we mean by saying that it is produced by the action of a constant accelerating force), is as the acceleration and the time jointly. Now, what we call the *angular velocity* is nothing but this momentary acceleration. Therefore the velocity v, generated in the time t, is $=\frac{F \cdot qG}{\int pr^2}t$.

Angular velocity.

The expression of the angular velocity is also the expression of the velocity v of a point situated at the distance 1 from the axis G.

Let z be the space or arch of revolution described in the time t by this point, whose distance from G is $=1$. Then $\dot{z} = v\dot{t} = \frac{F \cdot qG}{\int pr^2}t\,\dot{t}$, and taking the fluent $z=\frac{F \cdot qG}{\int pr^2}t^2$. This arch measures the whole angle of rotation accomplished in the time t. These are, therefore, as the squares of the times from the beginning of the rotation.

Those evolutions are equal which are measured by equal arches. Thus two motions of 45 degrees each are equal. Therefore because z is the same in both, the quantity $\frac{F \cdot qG}{\int pr^2}t^2$ is a constant quantity, and t^2 is reciprocally proportional to $\frac{F \cdot qG}{\int pr^2}$, or is proportional to $\frac{\int pr^2}{F \cdot qG}$, and t is proportional to $\frac{\sqrt{\int pr^2}}{\sqrt{F \cdot qG}}$. That is to say, the times of the similar evolutions of two ships are as the square root of the momentum of inertia directly, and as the square root of the momentum of the rudder or sail inversely. This will enable us to make the comparison easily. Let us suppose the ships perfectly similar in form and rigging, and to differ only in length L and l; $\int P \cdot R^2$ is to $\int pr^2$ as L^5 to l^5. For the similar particles P and p contain quantities of matter which are as the cubes of their lineal dimensions; that is, as L^3 to l^3. And because the particles are similarly situated, R^2 is to r^2 as L^2 to l^2. Therefore $P \cdot R^2 : p \cdot r^2 = L^5 : l^5$. Now F is to f as L^2 to l^2. For the surfaces of the similar rudders or sails are as the squares of their lineal dimensions; that is, as L^2 to l^2. And lastly, Gq is to gq as L to l, and therefore $F \cdot Gq : f \cdot gq = L^3 : l^3$. Therefore we have $T^2 : t^2 = \frac{\int P \cdot R^2}{F \cdot Gq} : \frac{\int p \cdot r^2}{f \cdot gq} = \frac{L^5}{L^3} : \frac{l^5}{l^3} = L^2 : l^2$, and $T : t = L : l$.

Times of similar evolutions with similar ships.

Therefore the times of performing similar evolutions with similar ships are proportional to the lengths of the ships when both are sailing equally fast; and since the evolutions are similar, and the forces vary similarly in their different parts, what is here demonstrated of the smallest incipient evolutions is true of the whole. They therefore not only describe equal angles of revolution, but also similar curves.

A small ship, therefore, works in less time and in less room than a great ship, and this in the proportion of its length. This is a great advantage in all cases, particularly in wearing, in order to sail on the other tack close-hauled. In this case she will always be to windward and ahead of the large ship, when both are got on the other tack. It would appear at first sight that the large ship will have the advantage in tacking. Indeed the large ship is farther to windward when again trimmed on the other tack than the small ship when she is just trimmed on the other tack. But this happened before the large ship had completed her evolution, and the small ship, in the meantime, has been going forward on the other tack, and going to windward. She will therefore be before the large ship's beam, and perhaps as far to windward.

We have seen that the velocity of rotation is proportional, *cæteris paribus*, to F × Gq. F means the absolute impulse on the rudder or sail, and is always perpendicular to its surface. This absolute impulse on a sail depends on the obliquity of the wind to its surface. The usual theory says, that it is as the square of the sine of incidence; but we find this not true. We must content ourselves with expressing it by some as yet unknown function φ of the angle of incidence a, and call it φa; and if S be the surface of the sail, and V the velocity of the wind, the absolute impulse is $nV^2S \times \varphi a$. This acts (in the case of the mizen-topsail, fig. 10) by the lever qG, which is equal to DG × cos DGq, and DGq is equal to the angle of the yard and keel; which angle we formerly called b. Therefore its energy in producing a rotation is $nV^2S \times \varphi a \times DG \times \cos b$. Leaving out the constant quantities n, V^2, S, and DG, its energy is proportional to $\varphi a \times \cos b$. In order, therefore, that any sail may have the greatest power to produce a rotation round G, it must be so trimmed that $\varphi a \times \cos b$ may be a maximum. Thus, if we would trim the sails on the foremast, so as to pay the ship off from the wind right ahead with the greatest effect, and if we take the experiments of the French academicians as proper measures of the oblique impulses of the wind on the sail, we will brace up the yard to angle of 48° with the keel. The impulse corresponding to 48° is 615, and the cosine of 48° is 669. These give a product of 411·435. If we brace the sail to 54·44, the angle assigned by the theory, the effective impulse is 405·274. If we make the angle 45°, the impulse is 408·774. It appears then that 48° is preferable to either of the others. But the difference is inconsiderable, as in all cases of maximum a small deviation from the best position is not very detrimental. But the difference between the theory and this experimental measure will be very great when the impulses of the wind are of necessity very oblique. Thus, in tacking ship, as soon as the headsails are taken aback, they serve to aid the evolution, as is evident. But if we were now to adopt the maxim inculcated by the theory, we should immediately round in the foreweather braces, so as to increase the impulse on the sail, because it is then very small; and although we by this means make the yard more square, and therefore diminish the rotatory momentum of this impulse, yet the impulse is more increased (by the theory) than its vertical lever is diminished. Let us examine this a little

A nice point of seamanship.

more particularly, because it is reckoned one of the nicest points of seamanship to aid the ship's coming round by means of the headsails; and experienced seamen differ in their practice in this manœuvre. Suppose the fore-yard braced up to 40°, the sail shivers, and from letting go the head bow-lines the sail immediately takes aback, and in a moment we may suppose an incidence of 6 degrees. The impulse corresponding to this is 400 (by experiment), and the cosine of 40° is 766. This gives 306·400 for the effective impulse. To proceed according to the theory, we should brace the yard to 70°, which would give the wind (now 34° on the weather-bow) an incidence of nearly 36°, and the sail an inclination of 20° to the intended motion, which is perpendicular to the keel. For the tangent of 20° is about $\frac{1}{2}$ of the tangent of 36°. Let us now see what effective impulse the experimental law of oblique impulsions will give for this adjustment of the sails. The experimental impulse for 36° is 480; the cosine of 70° is 342; the product is 164·160, not much exceeding the half of the former. Nay, the impulse for 36°, calculated by the theory, would have been only 346, and the effective impulse only 118·332. And it must be farther observed, that this theoretical adjustment would tend greatly to check the evolution, and in most cases would entirely mar it, by checking the ship's motion ahead, and consequently the action of the rudder, which is the most powerful agent in the evolution; for here would be a great impulse directed almost astern.

We were justifiable, therefore, in saying, in the beginning of this article, that a seaman would frequently find himself baffled if he were to work a ship according to the rules deduced from M. Bouguer's work; and we see by this instance of what importance it is to have the oblique impulsions of fluids ascertained experimentally. The practice of the most experienced seamen is directly the opposite to this theoretical maxim, and its success greatly confirms the usefulness of these experiments of the academicians so often praised by us.

We return again to the general consideration of the rotatory motion. We found the velocity $v=\frac{F\cdot qG}{\int pr^2}$. It is therefore proportional, *cæteris paribus*, to qG. We have seen in what manner qG depends on the position and situation of the sail or rudder when the point G is fixed. But it also depends on the position of G. With respect to the action of the rudder, it is evident that it is so much the more powerful, as it is more remote from G. The distance from G may be increased either by moving the rudder farther aft or G farther forward. And as it is of the utmost importance that a ship answer her helm with the greatest promptitude, those circumstances have been attended to which distinguished fine steering ships from such as had not this quality; and it is in a great measure to be ascribed to this, that, in the gradual improvement of naval architecture, the centre of gravity has been placed far forward. Perhaps the notion of a centre of gravity did not come into the thoughts of the rude builders in early times; but they observed that those boats and ships steered best which had their extreme breadth before the middle point, and consequently the bows not so acute as the stern. This is so contrary to what one would expect, that it attracted attention more forcibly; and, being somewhat mysterious, it might prompt to attempts of improvement, by exceeding in this singular maxim. We believe that it has been carried as far as is compatible with other essential requisites in a ship.

Of importance to determine the best place for a ship's centre of gravity.

We believe that this is the chief circumstance in what is called the trim of a ship; and it were greatly to be wished that the best place for the centre of gravity could be accurately ascertained. A practice prevails, which is the opposite of what we are now advancing. It is usual to load a ship so that her keel is not horizontal, but lower abaft. This is found to improve her steerage. The reason of this is obvious. It increases the acting surface of the rudder, and allows the water to come at it with much greater freedom and regularity; and it generally diminishes the griping of the ship forward, by removing a part of the bows out of the water. It has not always this effect; for the form of the ship's bow is sometimes such, that the tendency to gripe is diminished by immersing more of the bow in the water.

But waiving these circumstances, and attending only to the rotatory energy of the rudder, we see that it is of advantage to carry the centre of gravity forward. The same advantage is gained to the action of the after-sails. But, on the other hand, the action of the headsails is diminished by it; and we may call every sail a headsail whose centre of gravity is before the centre of gravity of the ship; that is, all the sails hoisted on the bowsprit and foremast, and the staysails hoisted on the mainmast; for the centre of gravity is seldom far before the mainmast.

Suppose that when the rudder is put into the position AD (fig. 11), the centre of gravity could be shifted to g, so as to increase qG, and that this is done without increasing the sum of the products pr^2. It is obvious that the velocity of conversion will be increased in the proportion of qG to qg. This is very possible, by bringing to that side of the ship parts of her loading which were situated at a distance from G on the other side. Nay, we can make this change in such a manner that $\int pr^2$ shall even be less than it was before, by taking care that everything which we shift shall be nearer to g than it was formerly to G. Suppose it all placed in one spot m, and that m is the quantity of matter so shifted, while M is the quantity of matter in the whole ship. It is only necessary that $m\cdot g\mathrm{G}^2$ shall be less than the sum of the products pr^2, corresponding to the matter which has been shifted. Now, although the matter which is easily moveable is generally very small in comparison to the whole matter of the ship, and therefore can make but a small change in the place of the centre of gravity, it may frequently be brought from places so remote that it may occasion a very sensible diminution of the quantity $\int pr^2$, which expresses the whole momentum of inertia.

A practice of seamen in putting about explained.

This explains a practice of the seamen in small wherries or skiffs, who, in putting about, are accustomed to place themselves to leeward of the mast. They even find that they can aid the quick motions of these light boats by the way in which they rest on their two feet, sometimes leaning on one foot, and sometimes on the other. And we have often seen this evolution very sensibly accelerated in a ship of war, by the crew running suddenly, as the helm is put down, to the lee-bow. And we have heard it asserted by very expert seamen, that after all attempts to wear ship (after lying-to in a storm) have failed, they have succeeded by the crew collecting themselves near the weather fore-shrouds the moment the helm was put down. It must be agreeable to the reflecting seaman to see this practice supported by undoubted mechanical principles.

The evolution accelerated by additional matter.

It will appear paradoxical to say that the evolution may be accelerated even by an addition of matter to the ship; and though it is only a piece of curiosity, our readers may wish to be made sensible of it. Let m be the addition, placed in some point m lying beyond G from q. Let S be the spontaneous centre of conversion before the addition. Let v be the velocity of rotation round g, that is, the velocity of a point whose distance from g is 1, and let ρ be the radius vector, or distance of a particle from g. We have $\frac{F\cdot qg}{\int p\rho^2+m\cdot mg^2}$. But we know that $\int p\rho^2=\int pr^2+\mathrm{M}\cdot\mathrm{G}g^2$.

Therefore $v=\frac{F\cdot qg}{\int pr^2+\mathrm{M}\cdot\mathrm{G}g^2+m\cdot mg^2}$. Let us determine G$g$ and mg and qg.

Let mG be called z. Then, by the nature of the centre

Seamanship.

of gravity, $\mathrm{M}+m:\mathrm{M}=\mathrm{G}m:gm=z:gm$, and $gm=\frac{\mathrm{M}}{\mathrm{M}+m}z$, and $m\cdot gm^2=\frac{m\mathrm{M}^2}{\mathrm{M}+m)^2}z^2$. In like manner, $\mathrm{M}\cdot\mathrm{G}g^2=\frac{\mathrm{M}m^2}{\mathrm{M}+m)^2}z^2$. Now $m\mathrm{M}^2+m^2\mathrm{M}=\mathrm{M}m\times\mathrm{M}+m$. Therefore $\mathrm{M}\cdot\mathrm{G}g^2+m\cdot gm^2=\frac{\mathrm{M}m\times(\mathrm{M}+m)}{\mathrm{M}+m)^2}z^2, =\frac{\mathrm{M}m}{\mathrm{M}+m}z^2$. Let u be $=\frac{m}{\mathrm{M}+m}$, then $\mathrm{M}\cdot\mathrm{G}g^2+m\cdot gm^2=\mathrm{M}nz^2$. Also $\mathrm{G}g=nz$, being $=\frac{m}{\mathrm{M}+n}z$. Let $q\mathrm{G}$ be called c: then $qg=c+nz$. Also let SG be called e.

We have now for the expression of the velocity $v=\frac{\mathrm{F}(c+nz)}{\int pr^2+\mathrm{M}nz^2}$, or $v=\frac{\mathrm{F}}{\mathrm{M}}\times\frac{c+nz}{\frac{\int pr^2}{\mathrm{M}}+nz^2}$. But $\frac{\int pr^2}{\mathrm{M}}=ce$.

Therefore, finally, $v=\frac{\mathrm{F}}{\mathrm{M}}+\frac{c+nz}{ce+nz^2}$. Had there been no addition of matter made, we should have had $v=\frac{\mathrm{F}}{\mathrm{M}}\times\frac{c}{ce}$.

It remains to show, that z may be so taken that $\frac{c}{ce}$ may be less than $\frac{c+nz}{ce+nz^2}$. Now, if c be to z as ce to z^2, that is, if z be taken equal to e, the two fractions will be equal. But if z be less than e, that is, if the additional matter is placed anywhere between S and G, the complex fraction will be greater than the fraction $\frac{c}{ce}$, and the velocity of rotation will be increased. There is a particular distance which will make it the greatest possible, namely, when z is made $=\frac{1}{n}(\sqrt{c^2+nce}-c)$, as will easily be found by treating the fraction $\frac{c+nz}{ce+nz^2}$, with z, considered as the variable quantity, for a maximum. In what we have been saying on this subject, we have considered the rotation only inasmuch as it is performed round the centre of gravity, although in every moment it is really performed round a spontaneous axis lying beyond that centre. This was done because it afforded an easy investigation, and any angular motion round the centre of gravity is equal to the angular motion round any other point. Therefore the extent and the time of the evolution are accurately defined. From observing that the energy of the force F is proportional to qG, an inattentive reader will be apt to conceive the centre of gravity as the centre of motion, and the rotation as taking place, because the momenta of the sails and rudder, on the opposite sides of the centre of gravity, do not balance each other. But we must always keep in mind that this is not the cause of the rotation. The cause is the want of equilibrium round the point C (fig. 10), where the actions of the water balance each other. During the evolution, which consists of a rotation combined with a progressive motion, this point C is continually shifting, and the unbalanced momenta which continue the rotation always respect the momentary situation of the point C. It is, nevertheless, always true, that the energy of a force F is proportional, *cæteris paribus*, to qG, and the rotation is always made in the same direction as if the point G were really the centre of conversion. Therefore the mainsail acts always (when oblique) by pushing the stern away from the wind, although it should sometimes act on a point of the vertical lever through C, which is ahead of C.

The rotation performed round a spontaneous axis.

These observations on the effects of the sails and rudder in producing a conversion, are sufficient for enabling us to explain any case of their action which may occur. We have not considered the effects which they tend to produce by inclining the ship round a horizontal axis, viz., the motions of rolling and pitching. To treat this subject properly would lead us into the whole doctrine of the equilibrium of floating bodies, and it would rather lead to maxims of construction than to maxims of manœuvre. M. Bouguer's *Traité du Navire* and Euler's *Scientia Navalis* are excellent performances on this subject, and we are not here obliged to have recourse to any erroneous theory.

Different operations of the water on the ship and wind on the sails balance each other.

It is easy to see that the lateral pressure both of the wind on the sails and of the water on the rudder tends to incline the ship to one side. The sails also tend to press the ship's bows into the water, and if she were kept from advancing, would press them down considerably. But by the ship's motion, and the prominent form of her bows, the resistance of the water to the fore part of the ship produces a force which is directed upwards. The sails also have a small tendency to raise the ship, for they constitute a surface which in general separates from the plumb-line below. This is remarkably the case in the staysails, particularly the jib and fore-topmast staysail. And this helps greatly to soften the ship's bows into the head seas. The upward pressure also of the water on her bows, which we just now mentioned, has a great effect in opposing the immersion of the bows which the sails produce, by acting on the long levers furnished by the masts. M. Bouguer gives the name of *point velique* to the point V (fig. 12) of the mast, where it is cut by the line CV, which marks the mean place and direction of the whole impulse of the water on the bows. And he observes, that if the mean direction of all the actions of the wind on the sails be made to pass also through this point, there will be a perfect equilibrium, and the ship will have no tendency to plunge into the water or to rise out of it; for the whole of the water on the bows, in the direction CV, is equivalent to, and may be resolved into the action CE, by which the progressive motion is resisted, and the vertical action CD, by which the ship is raised above the water. The force CE must be opposed by an equal force VD, exerted by the wind on the sails, and the force CD is opposed by the weight of the ship. If the mean effort of the sails passes above the point V, the ship's bow will be pressed into the water; and if it pass below V, her stern will be pressed down. But, by the union of these forces, she will rise and fall with the sea, keeping always in a parallel position. We apprehend that it is of very little moment to attend to the situation of this point. Except when the ship is right before the wind, it is a thousand chances to one that the line CV of mean resistance does not pass through any mast; and the fact is, that the ship cannot be in a state of uniform motion on any other condition but the perfect union of the line of mean action of the sails, and the line of mean action of the resistance. But its place shifts by every change of leeway or of trim; and it is impossible to keep these lines in one constant point of intersection for a moment, on account of the incessant changes of the surface of the water on which she floats. M. Bouguer's observations on this point are, however, very ingenious and original.

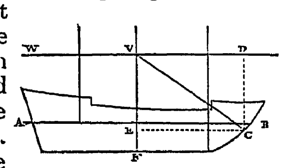

Fig. 12.

Action of the rudder upon the ship described.

To prevent unnecessary complication in this treatise, it has been supposed, what is no doubt correct in theory, that the helm acts upon the ship in the same proportion, only producing exactly contrary effects, whether the vessel is going ahead or astern. But in practice this is not the case, and the reason is as follows:—In general a ship is so constructed, unless brought down extremely by the stern, that with headway, sailing with a side-wind, the natural tendency of the bow of the vessel is to approach the wind. That is prevented, partly by the sails before the centre of

Seamanship.

gravity being larger than those abaft, and partly by keeping the helm a little a-weather. As soon, however, as the ship get stern-way, she acquires a tendency to fall off from the wind, in the same proportion as her tendency was to approach the wind, as long as the vessel went ahead. But on account of the larger size of the sails forward to those abaft, this tendency to put before the wind is so increased, that with a very moderate breeze, a ship, when making a stern-board, soon pays off against her helm, until the wind is on the quarter. No doubt the helm will counteract this motion to some extent, but in practice the effect is hardly perceptible.

The substance of this article, up to this point, has been taken from one written by the celebrated Professor John Robison, for a former edition of this work. The course of adopting Professor Robison's treatise as a groundwork has been taken, not only out of deference to the high authority of that author, but it is also believed that the interests of the readers of the *Encyclopædia* have been considered in this matter. We have indeed the means of knowing that the original article has been of extensive utility.

Chief evolutions described.

We shall now, instead of repeating the evolutions, which are described by the Professor, give a few examples of the manner in which a ship is manœuvred, in order to elucidate the theory which has been already explained.

To tack ship, in smooth water, with a fine breeze, and under all sail.—Everything being ready, the ship is gradually luffed up, putting the helm down slowly, at the same time hauling over, until nearly amidships, the spanker-boom. As soon as the helm is down, the word is given, the "helm is a-lee," immediately the fore and head sheets are let go. As soon as the wind is fairly out of the after-sails, or when the ship is about three points from the wind, the order is given to raise tacks and sheets. As the ship approaches to about half-a-point of being head to wind, the after-yards are braced round, and their sails trimmed. As soon as she commences fairly to fall off on the new tack, the order is given of "all haul;" then the head-yards are braced round, and all the sails are trimmed. During this evolution the way of the ship must be watched, and if lost, the helm must be righted; if the ship gets stern-way, the helm must be shifted.

The above is the ordinary process of tacking ship under favourable circumstances; a process in which all the different modes of action of the rudder and sails may be employed. To execute this evolution in the most expeditious manner, and so get the ship as much as possible to windward, is considered as the test of an expert seaman.

A fast-sailing ship, just able to carry three reefs out of the topsails and top-gallant sails, working to windward under the above-mentioned circumstances, ought to make about 9 knots per hour, and sail within five and a-half points of the wind. Such being the case, and supposing half-a-point leeway to be made, if nothing was lost in stays, the ship would go to windward at the rate of 3·4 miles per hour. Perhaps 0·3 of the whole distance run may be considered good for a square-rigged vessel.

We have here supposed that, during this operation, the ship has preserved, or nearly so, her progressive motion. She must therefore have described a curved line, advancing all the time to windward; and the ship has been tacked without much assistance from the sails, but principally by the action of the rudder. But this evolution has often to be performed when, either from a swell, want of wind, or, on the other hand, too much wind, sluggishness of the vessel, or from too little sail being set and the ship having little velocity, there arises a considerable probability that, unless great care is used, the ship may not stay, or as it is technically called, may miss stays. Under these circumstances the skilful sailor will adopt many devices, which are neither necessary nor useful, when he is placed in a more favourable situation. For instance, before putting the helm down, the jib-sheet ought to be eased off, or perhaps the jib hauled down. As soon as the word "helm-is-a-lee" is given, besides the fore-sheet, the foretop-bowline is also let go, and the weather-foretopsail-brace is hauled in, the yard to be braced up again as soon as the ship approaches within two points of being head to wind. When the word "raise tacks and sheets" is given, the fore-tack is to be kept fast until the ship is head to wind. The after yards ought not to be hauled until the ship is quite head to wind. The shaking of the spanker under these circumstances affords a good guide to show when the after-yards ought to be braced round. During the time occupied by this evolution, the way of the ship ought to be watched; and as soon as the ship begins to go astern, the helm ought to be shifted. Sometimes it is necessary that the ship should have well paid off on her new tack, before the head-yards are braced round, otherwise the vessel may be placed in what is called irons; that is to say, for some considerable time her head will not pay off either way, and the ship during this time is going astern.

If the ship loses all her headway after the headsails have taken aback, but before the wind has been brought right ahead, the evolution becomes uncertain, but by no means hopeless. Under these circumstances, the ship will soon have stern-way, and the helm must then be shifted hard over. It is evident that the resistance of the water to the stern-way of the rudder will act in a favourable direction, pushing the stern outwards. In the meantime, the action of the wind on the headsails pushes the head in the opposite direction. These actions conspire, therefore, in promoting the evolution; and if the wind can be brought right ahead, it cannot fail, but may even be completed speedily. As soon as the wind comes on the former lee-bow, the action of the water on the now lee-quarter will greatly accelerate the conversion. Therefore, when the wind has once been brought right ahead, there is no risk of failure.

To get under Weigh.—When a ship's anchor is to be weighed, the head-yards are braced round to the opposite tack to which it is intended to cast the ship, the after-yards being braced upon the other tack. Supposing it is intended to cast upon the port tack, the helm will be ported, but shifted when the anchor is out of the ground, and the ship commences to get stern-way. As soon as the head sails will take on the port tack, they are hoisted, and after that, the head-yards braced round, and the sails properly trimmed.

To wear Ship.—Put the helm up, and brail up the after-sails, round in the weather after-braces, keeping the mizen-topsail shivering, and the main-topsail just touching. When the wind is about one point abaft the beam, let go the head bowlines, and get a pull of the weather head-braces. This is preferable to the usual plan of not touching the head-yards, until the wind is well on the quarter. When the wind is nearly aft, square the head-yards; and when it comes on the other quarter, haul out the spanker, shift over the head-sheets, righting the helm in time, and brace sharp up. We cannot help losing much ground in this movement. Therefore, though it be simple, it requires attention and rapid execution to do it with as little loss as possible. At first one is apt to think, that it would be better to keep the head-sails braced up on the former tack, until the ship is nearly before the wind; as we might expect assistance from the obliquity of the head-sails. But the rudder being the principal agent in the evolution, it is found that more time is gained by increasing the ship's velocity than by an impulse upon the head-sails more favourably directed. It has been considered by many seamen, that a ship, when she cannot be stayed, loses the least ground by what is termed box-hauling. This is effected by bracing the head-yards flat aback as soon as the

helm is put up, and keeping the after-sails shivering; when the ship gets stern-way, the helm is shifted, to be righted when she gathers headway; when before the wind, square the yards, and proceed as in wearing. This evolution, if well done, may be useful if some danger be suddenly seen right ahead.

In a strong gale with a contrary wind, or even with a fair wind with too heavy a sea to run with safety, the ship is obliged to lie to. Some sail is absolutely necessary to keep the ship steady, otherwise she might strain and work herself to pieces. Different ships behave best under different sails. In a very violent gale, the main-topsail close reefed, storm-trysails and fore-staysail are in general well adapted for keeping a ship steady, and distributing the strain. Under this sail, unless a very heavy sea is running, the ship will have sufficient way to be steered. This is far preferable to the plan adopted before storm-trysails had superseded storm-staysails; the helm used then to be kept a-lee, and the ship's head came up and fell off, the same as a ship hove to in fine weather, with a main-topsail aback.

To take in a topsail during a gale of wind.—Let go the top-bowline, lower the yard, and slack about 4 feet of the lee-sheet. Clew the yard down by the weather clewline, and haul in the weather topsail brace. As soon as the yard is down, ease away the weather-sheet, and haul up the clewline and buntline; when up, ease off the lee-sheet, and haul up the lee clewline and buntline.

To set a topsail blowing hard, the lee-sheet must first be hauled home.

Omitting the details, which we do not pretend to give, the above shows the principle upon which square sails are set and taken in during gales of wind.

Dangerous position of the Magnificent, and her preservation from it described.

In closing this head, we would refer to one of the finest manœuvres of seamanship, and one which has been fully recorded, we mean the saving from a most perilous position Her Majesty's ship Magnificent, of 74 guns, commanded by Captain John Hayes. The following are some of the particulars:—

On the evening of December 16, 1812, the Magnificent anchored with the best bower in 16 fathoms, between Chasseron and Isle of Rhe, in the neighbourhood of the Basque Roads, at 9 h. 40 m. P.M. The ship drove, when the small bower anchor was let go, and brought the ship up in 10 fathoms, the Isle of Rhe reef being distant about the length of two cables. The lower yards and topmasts were immediately struck. By the lead it was soon discovered that they were anchored amongst rocks; and as they were without chain-cables, it was quite obvious the hempen cables would soon be chafed through. The gale continued, with squalls from the S.W., with rain, and a heavy cross sea running. At daylight the ship again drove, and the spare anchor was let go, which brought her up. At noon the gale had increased, without any indication of a favourable change in the weather, joined to which one of the cables having parted, Captain Hayes resolved to make an attempt to save the ship. The courses having been previously reefed, and the topsails close-reefed, the lower yards were swayed up to three-fourths of their usual height; the topmasts were secured close down, leaving the topsail-yards to work on the caps; the largest hawser was passed through the starboard quarter-port, and bent to the cable of the small bower, for the purpose of acting as a spring in casting the ship to port previously to cutting the cable.

The courses and topsails were secured on their respective yards with stops of spun yarn, the gaskets having been removed. The head and main yards were braced up on the starboard tack, the yards on the mizen-mast being kept square. It is quite evident that, in the event of the spring canting the ship, the head-yards would require no alteration. On the other hand, if the spring broke, the yards could not be better placed for producing the stern-board, which would in that case be necessary to clear the reef. The spring was now hove in to a tolerable strain, and all being ready, the cables were cut. The heavy sea on the port-bow acting against the spring, caused it to snap; it was immediately cut adrift to prevent retarding the ship's way, the helm was put hard to starboard, the fore-staysail hoisted, the fore-topsail let fall and sheeted home, the foresail let fall, the tack hauled on board, and the sheet roused aft. All this sail was flat aback, and set in less than half-a-minute. The ship's head paid round quickly towards the reef. When the wind was abaft the beam, the mizen-topsail was set, and the helm shifted. When the wind came right aft, the main-topsail was set, and immediately afterwards the mainsail. As soon as the wind came on the starboard quarter, the sails were trimmed, and the yards braced up on the starboard tack. Thus the ship was saved.

This manœuvre, from the cutting of the spring until the sails were set, did not exceed two minutes. At the moment when the ship's head was in the direction of the rocks, and then only in five fathoms water, the vessel made a desperate plunge; and in hauling to the wind, the send of the sea did not leave, by the soundings, more than a single foot of water under the keel.

Late improvements in art of seamanship.

We now propose to direct attention to the most important improvements in the art of seamanship which have taken place within the last fifty years. This science, as it may now fairly be called, has greatly advanced within that period. With the improvements which have been made in most other departments of industry and knowledge, the public are more or less familiar, and great pains have been taken throughout this work to extend that familiarity by such popular explanations as shall not only be intelligible to general readers, but be useful to those whom pleasure or business inclines to go deeper. But before explaining the more recent changes that have taken place in this art or science, we would direct some attention to its general progress.

Most other sciences may be studied with effect in the closet. An amateur astronomer, for example, or a chemist, furnished with good instruments, and having confidence in the skill and good faith of the leaders in the particular walk of knowledge to which his taste inclines him, may, by adopting their results, pursue the same paths with almost equal profit, and perhaps with more pleasure than those who take all the labour and incur all the responsibility. But there is no royal road of this sort by which an amateur sailor can investigate the results of seamanship, the mysteries of which, to be fully understood, must be studied afloat, at sea, in all weathers, and in every climate.

All the world, however, knows that the results of nautical skill and exertion are not the same as they used to be. A voyage to India and back, in former times, occupied a couple of years, or more; it is now currently done in eight months, even by ordinary merchant-vessels, including the time taken to unload and reload their cargoes. In consequence of the increase of passengers between England and Australia, great emulation has been excited amongst the merchant-ships running between the two countries, and many improvements have taken place. That voyage is now often performed (without the aid of steam) in eighty days, and has been done in seventy. It is recorded that one of these clipper ships, as they are designated, has run the enormous distance of nearly 3000 miles in ten days. In former days, the scurvy struck down half the crew of every ship which made a long voyage, and was even fearfully prevalent in the navy; now the disease is almost unknown. The numbers of all kinds of ships afloat have enormously increased, and the war of the elements by which they were formerly assailed is no less violent than it was; but assuredly a far smaller proportion of vessels are now driven on shore than

Seamanship.

were formerly wrecked. The comforts, too, of travelling by sea, in the articles of provisions and water, are all essentially improved; and, finally, the security, as well as the happiness of all persons on board, whether passengers or crew, has been marvellously augmented by the general establishment of a better system of discipline than was known in bygone days; whilst many old manipulations of seamanship are so modified by new contrivances, that if old Benbow, or even Kempenfelt, were to arise from the dead, he would scarcely know how to handle his ship.

Best courses in passing through the tropics.

It may not be without use, and it certainly must be interesting to those who have not studied such things personally, to see by an example how scientific seamanship is made to triumph over that groping and blundering method of navigating ships which is technically known by the name of the "rule of thumb." If we take a globe, and trace on it the shortest route, by sea, to India, and then fancy that such must be the best course to follow, we shall be very much mistaken. And yet this is very much what our ancestors actually did, till time, and repeated trials, and multitudinous failures, gradually taught them where to seek for winds, and how to profit by them when found. According to the "rule of thumb" sailing, a ship had only to steer from England to Madeira, pass the Canaries and Cape de Verds, and then to make a direct course to the Cape, and thence to India. On trial, however, this experiment always failed; for on getting near the equator, a series of calms and squalls put a stop to this straight-line scheme, and the mariners of old were then forced to toil along the coast of Africa, or were driven towards that of the Brazils, and very often they came back in utter hopelessness. Now-a-days, the exact spot where the north-east trade wind, which prevails in the northern Atlantic, ought to be parted with; in what district the calms and variables are most easily managed; over what degree of longitude on the equator the ship should pass; and, finally, in what place the south-east trade wind of the southern Atlantic is to be found, and how it is to be made most use of when found,—are all matters of such familiarity to the really qualified navigator, that they scarcely occupy his thoughts, but are acted upon as matters of course, and, unless some unforeseen accident occurs, absolutely ensure the success of his voyage. The line he follows, however, is by no means the straight one which an ill-informed person would naturally have chalked out for him to follow, ignorant of the impossibility of pursuing it.

The modern navigator, by not seeking to husband the south-east trade wind too much, but by freely "flanking" through it, sweeps past the coast of Brazil, and by boldly dashing down into pretty high south latitudes, is certain, or almost certain, of finding there such a vein of westerly wind, as amply compensates for the apparent roundabout he has made in his course. In like manner, after passing the Cape, which to the old navigators was truly a "Cabo de tormentos," instead of vainly trying to reach India by steering straight through the Mozambique Channel, the scientific navigator, disregarding the increase of distance, maintains his position in a high latitude, and sails resolutely along a parallel of latitude, with the wind in his poop, till he has obtained such a degree of easting, that, on hauling up to the northward, and making for the south-east trade wind, he enters that mysterious aërial current on such terms as ensure his making it serve his purpose. If, however, he be timid or impatient by nature, and not duly instructed by experience, he will be very apt to haul up too soon to the northward, from not liking to run, as it appears, so far past his port. The consequence will be, that when he encounters the south-east trade wind, he will find, that instead of its being fair, it is blowing in his teeth, and he will have to run back again to the southward to borrow a little more easting from the westerly breezes which prevail there.

Be it observed, however, that the above instructions would lead a seaman into great error, were he to make the rule absolute; for, at certain seasons of the year, that is, when the sun is far to the north of the line, and the south-west monsoon blowing in the Indian Ocean, his course from the Cape to India would lead him between Madagascar and the main land of Africa; and so he would sail across the equator, and enter the Bay of Bengal with a flowing sheet. At other seasons, so far from having a flowing sheet on reaching India, he may have to beat up the bay, "hank for hank," unless he has knowledge enough to know at which side to enter it, and skill enough—for it requires a good deal—to know how to profit by the land and sea breezes of the coasts respectively of Coromandel and of Pegu.

In short, not to swell this example too far, the truly scientific navigator, possessed of the requisite nautical instruments (the most important of which we propose to speak of by and by), by which means he may at all times be certain of his place, may almost command a fair wind at every stage of his voyage, and thus secure his passage within a certain number of days; though, in his way, he will have had to vary his course a hundred times from that which, at first sight, might have been thought the best, merely because, on the map, it seemed the shortest. The old proverb, indeed, which warns us that the longest way about is often the shortest way home, has perhaps its amplest illustration in the practice of modern seamanship; but, let it be always borne in mind, that this is true only when all the varying circumstances of time and place are duly taken into account, and so appropriated as to give to the ship those advantages of fair wind and moderate weather without which no voyage can be securely or speedily made. This branch of seamanship, therefore, more than any other, requires for its successful exercise a singular combination of the widest generalizations in theory, with the most minute and specific disintegrations of scientific research in practice. In the Indian seas especially, the whole history of the winds, examined without some theoretical clue, is a mass of confusion; and yet the profoundest meteorological science would inevitably prove not only useless, but absolutely dangerous to the navigator who should trust to it alone, without the aid of local information, and of the improvements of modern art.

Effects of the introduction of steam in nautical affairs.

The first great improvement of recent times to which we shall allude, is the mighty revolution in nautical affairs brought about by the introduction of steam. We may notice in passing, that the first instance we have of the application of steam-power to propel vessels in this country took place in 1815, and Glasgow led the way. No doubt, steam-engines had been tried on board ships before that time, but in 1815 commenced the first commercial employment of steam-vessels. In the beginning of 1816, a small steam-vessel, of about ten horse-power, began running as a passage-vessel between Sheerness and Chatham. Immediately after that steam-vessels were used upon the Thames. The first time that they made coasting sea-voyages was in 1821, when they commenced running between London and Edinburgh. The first of what may be called an ocean-voyage took place in 1826, when two steam-vessels commenced running between London and Lisbon. Our present object, however, is not to give a history of steam as applied to navigation, but to notice that change, so far as seamanship proper is concerned. For fuller explanations of the subject, and its progress, we would refer to the article STEAM-ENGINE.

Now, to a considerable extent, steam does not essentially interfere with seamanship proper, the manipulations of which remain nearly as before; whilst steam navigation, in spite of its boasted contempt of wind and tide, is still obliged to borrow so much from seamanship to complete its success, that without its aid it would often be useless, and even dangerous in the highest degree. It is quite evident,

that nearly all that branch of our subject which relates to navigation; that is, to the method by which a ship's place is determined at sea, the proper course shaped, and the different ports of the world recognised and made use of, remains the same. Latitudes and longitudes, and the variation of the compass, are evidently just as important to a steam-vessel as to a sailing one; and though winds and currents are not quite so essential, every one who has made a steam voyage of any length is aware how materially its celerity depends upon a knowledge of and due attention to these particulars. It is one of the chief points of a seaman's duty to know where to find a fair wind, and where to fall in with a favourable current; but the obligation, if not equally binding on a steam navigator, is so, to a certain extent, when his voyage is a long one. The most remarkable occasions on which steam has the advantage over sails are in a calm, and when the wind is directly ahead. In a calm, a sailing ship is utterly helpless, and must stand stock-still; with a wind in her teeth, if it blow hard, she can do nothing, or does worse than nothing, drifts away from her point. Although the above statements, as far as they go, are true to the letter, still there are other points of seamanship connected with steam that now can only be acquired on board steam-vessels; one of such points, of most importance, is the best and most efficient mode of combining steam with the use of sails, and to which we would first draw attention.

Remarks upon best mode of combining steam with use of sails.

When first the steam-engine was applied to the propulsion of vessels, the propeller universally adopted was the paddle-wheel; and a general idea existed, that sails under these circumstances were of very little use; acting upon this notion, these vessels were fitted with very small masts and yards. But as soon as we commenced to have steam men-of-war, it was apparent, that if they were not provided with the power of moving under sail alone, so as to save burning their coals, their utility for distant stations, and cruising with a fleet, would be much curtailed. For the above reasons, steam men-of-war, even before the introduction of the screw, were being gradually fitted with loftier masts and squarer yards; so that, by the year 1846, our steam frigates had in general about three-fourths the same extent of canvas that they would have had as sailing ships of the same dimensions. To render these vessels at all effective under sail alone, the wheels had either to be disconnected, or the floats taken off. But even after either of these plans had been adopted, the vessel, owing to its cumbrous paddle-boxes, remained an indifferent sailing vessel. Under these disadvantages, the introduction of the screw as a propeller made here a most important change. A screw-vessel, with its screw hoisted up, becomes as well fitted for sailing as any other vessel; and as the engines can be placed under the water-line, therefore protected from shot. This mode of propulsion was quickly adopted for the navy, and the ships so fitted are now rigged the same as if they had no steam, but were simply sailing-vessels. We need hardly add, that in future no men-of-war will proceed to sea without steam-engines being placed on board. The mercantile world were not slow in adopting screw-vessels; and at present they are not only employed in the coasting trade, but largely in the foreign commerce of the country. Although many of these vessels have great steam-power placed on board, still in a considerable number the power is small in proportion to their tonnage. In all cases large fore and aft sails are fitted for shorter voyages, and they are fully rigged for the longer ones. Although the screw has to a great extent taken the place of the paddle-wheel, and entirely so in the navy, yet, for the mercantile marine and post-office packets, under certain circumstances, the paddle-wheel is still used; for instance, in rivers, and for distant voyages, where strong head winds may be expected, and where a few hours even of delay may be of consequence. Thus we see, that a further advance in the science of steam navigation has had the effect of restoring the use of sails where engine-power is used. It would, indeed, be a disgrace to modern science if such a cheap and powerful agent as the wind could not be applied for our benefit, and that our discoveries only forced us to have recourse to expensive methods to gain our object. The action of the winds as a moving power is now brought under subjection, to be used when it is favourable; but at times when such is not the case, we then, and not till then, ought to have recourse to that power which we have in reserve. It is certainly comparatively easy to have a mere sailing-vessel, or a mere steamer. It is the combination of the two qualities which forms the desideratum, and to which we would now draw attention.

Often with men-of-war the length of a passage is of little moment, in these cases the sails alone ought to be used. But, on the other hand, in post-office packets and mercantile vessels with passengers, time is of so much importance, that if the supply of fuel be sufficient, it is their policy to push on; but there are a great variety of cases, where, although no extreme haste is necessary, yet it is of importance that the voyage should not be protracted beyond a certain time; in those cases a judicious employment of steam and sail is of consequence.

To aid a further elucidation of this subject, we propose now to give a table of the velocity and pressure of the wind:—

	Velocity in miles per hour.	Pressure on a square foot. lbs.	oz.
Light breezes	3·25	0	0·83
Moderate breezes	6·5	0	3·33
Fresh breezes.	16 25	1	5·0
Fresh gale	32·5	5	3 0
Strong gale	56·29	15	9·0
Hurricane	79·61	31	3 9
Violent hurricane	97·5	46	12·0

From this table it appears that the pressure of the wind increases as the square of its velocity; and as the power necessary to overcome the resistance to the speed of the ship is in all cases as the cube of her velocity, the following circumstance is therefore deducible. With a ship propelled by steam, if twice the velocity is to be attained, eight times the power must be used; but under sail (all things remaining the same, and a similar number of square yards of canvas spread), then wind, with three times its former velocity, would give rather more than twice the speed. But take the action of the wind in another point of view, and suppose a ship, with her steam up, going before the wind; if the velocity of the ship be greater than the wind, it is quite evident that the sails would only be a hindrance; but supposing that there is some difference, and that the ship is going slower than the wind, then all the assistance that the ship can receive is the difference between her velocity and the velocity of the wind. From this it is evident, that in a steam-vessel, when the wind is aft, or nearly so, the economical policy is to put the ship under sail alone, and not to use the steam at all, for by so doing, the whole power of the wind is made available. On the other hand, a light breeze on or abaft the beam, otherwise of little importance, may be taken advantage of in the propelling of the ship, by combining with it the power of steam. The reason is this. The ship passing rapidly along creates a considerable breeze; this unites with the wind, no doubt causing it to act more forward upon the ship in the same proportion as it increases its strength. From this we learn, that with light breezes on or about the beam, policy directs to make sail, but also to retain the steam, as it is by the velocity imparted by the engines to the vessel that these light winds become available.

It is not necessary to enlarge farther upon this subject,

as in a former part of this treatise (and the principle is the same) we demonstrated, that a fast ship, under sail alone, with the wind abaft the beam, might go faster than the ordinary current of the wind; although, no doubt, such cases seldom occur. With regard, however, to a vessel propelled by steam it is very different. In this case it will often happen, under the circumstances stated above, that the way of the ship will be increased by the power of the apparent wind, whilst the real wind has not the velocity of the vessel.

Mistake frequently committed in steam sailing.

In connection with this subject, we would now draw attention to a mistake which sailors in charge of steam-vessels sometimes have committed. The mistake made is this. In order, as they consider, to save coals, they keep the steam so low, with sail set, as not to turn the screw or paddle-wheel so fast as the vessel would go under sail alone. We have read an account of a voyage intended to show the advantage of using the sails and steam combined; and although attention is drawn to the small quantity of coal thereby consumed, yet, upon examination, there can be no doubt that the vessel would often have gone faster if the steam had not been used at all, and in such cases there would have been a saving of the whole of the coal.

The principles involved are as follows. With a fair wind, the number of miles obtained from a ton of coals is the number of miles that the engines increased the speed of the vessel above that which she would have gone with sails alone; that is to say, suppose a steam-ship goes nine knots with a fair wind, under sail alone, steam is applied, and the ship goes ten knots; the consumption of coal is, say two tons per hour, then 0·5 knot is obtained from each ton of coal. But now, under the same circumstances, suppose that a comparatively small amount of steam is applied, then it will follow that, unless a sufficiency of coal is used to keep up the revolutions of the screw or paddle-wheel equal to what would be the rate of the ship under sail alone, the way of the ship is less under sail, and this small supply of coal, than it would have been under sail alone; in short, the coal used in such a case would only retard the ship; and from this it may be deduced, that although fore and aft sails, and square sails also, when the wind is not too far forward, with the steam, may, under certain circumstances, often be useful, and save coal; so that, when the object is to make quick and economical passages, steam and sail ought certainly to be combined. Still it is advisable that steam and sail be generally used separately.

With strong head winds, the seaman often finds in his steam-vessel he is burning a large quantity of coal, more particularly if propelled by a screw, and making little way. In such cases the best plan is to keep the ship away and make sail, and if time is an important object, still keeping the screw in motion. So situated, even a dull sailing-vessel with small steam-power, if judiciously handled, will work to windward with considerable celerity.

We have already given an outline of the courses usually followed by a sailing-ship in passing through the tropics. In similar voyages, however, a vessel with steam-power has great advantages; and the skilful seaman would take a much shorter route, regulated of course, first, by his supply of coals and the time of their probable duration, and, secondly, by calculating the importance of time in opposition to expenditure of fuel.

Two voyages made by the Terrible described.

We now propose to give a short account of two voyages made by Her Majesty's steam-frigate Terrible, where sail and steam were combined, and which will therefore show the results of this combination; and as they were made through the tropics, these voyages will also prove that a much more direct and shorter route in such cases can be advantageously taken by steam-vessels than by mere sailing ships. It is necessary, first, to premise, that the Terrible was a steam-frigate carrying heavy armaments of guns, both on the main and upper decks. The Terrible's size was 1847 tons, with 800 horse-power of engines, stowing about 500 tons of coal, barque-rigged, and spreading about the same quantity of canvas as the old 44-gun frigates. It is also proper to state, that during both these voyages, when the steam was employed, it was used as expansively as possible, and with only two boilers, there being four on board for full power. The length of the stroke was 8 feet; the steam was cut off at 22 inches.

The first voyage was performed in August 1847, and was from Madeira, in Lat. 32. 58. N., Long. 16. 55. W., to St Paul de Loando, Lat. 8. 48. S., Long. 13. 13. E. The following is a short summary of the particulars of this voyage, and which requires no explanation :—

Shortest distance between Madeira and St Paul de Loando	3547	miles
Actual distance run by ship	3714	„
Total time occupied	27	days
Under sail alone	20	„
Under steam	156	hours
At anchor	18	„
Distance gone under sail alone	2374	miles
Under steam	1340	„
Whole hourly average rate of going	5·9	„
Total consumption of coal	252	tons

The equator was crossed in Long. 6. 0. E. It is quite obvious from the above table, that the Terrible, in this voyage, took almost the nearest possible route; now, every one at all acquainted with the winds and currents on the African coast to the southward of the line, is well aware that such a plan in a sailing-vessel is totally out of the question, and if attempted might even have prolonged the vogage for months.

The second voyage, concluding October 7, 1847, was from St Paul de Loando to Lisbon; and the following is a table similar to the one given for the previous voyage :—

Shortest distance between St Paul de Loando and Lisbon	4233	miles
Actual distance run by ship	4490	„
Total time occupied	30	days
Under sail alone	21	„
Under steam	224	hours
Distance gone under sail alone	2500	miles
Under steam	1990	„
Whole hourly average rate of going	6·23	„
Total consumption of coal	354	tons

The equator was crossed in Long. 13. 0. W. It will be observed that the same principle was adopted in the second voyage, namely, to make as nearly as possible a direct course. After the Terrible crossed the line, a nearly straight course was made up to 30. N. Lat., steaming through the N.E. trades, passing between Africa and the Canary Islands.

We have now shown that even in long voyages the steam-ship has an immense superiority over the sailing-vessel. We may, however, observe further, that she still retains that superiority under circumstances where both description of vessels are forced to anchor upon a dangerous lee-shore. From the anchors not holding, or the insufficient strength of the cables, there is then risk of their being forced on shore. But in this predicament, a steam-vessel, by the mere agency of her steam, although not exerted to any great extent, will either keep the cable slack, or at all events very materially relieve it from the strain produced by the wind.

There are many other details constantly arising on board steam-vessels, such as taking ships in tow, &c. These are operations which, to do well, require good seamanship; but, as we believe, that they can only be fully and practically learned on board a steam-vessel, it is hardly necessary to enter further upon these arrangements than we have done already.

There is, however, a very natural consideration that arises from the fact, that the royal navy is now entirely steam, and

Skill in some points of seamanship deteriorated.

that the mercantile marine is gradually becoming so. The consideration we allude to is this, Has this change deteriorated our skill and knowledge of seamanship? In our own opinion, to a certain extent, it has, not that our ships are worse rigged or worse handled in any way, in the open sea, but officers and pilots are gradually shrinking from performing those manœuvres that were formerly often executed by mere sailing-vessels, close to the shore or in narrow passages. Suppose, for example, a ship placed, in the present day, in the same position as the Magnificent, which we have already described, most probably she would have steam-power, by which aid the ship could be easily extricated; but if not, it appears to us very doubtful whether the daring manœuvre which saved that ship would now be attempted under sail alone. Formerly it was quite common for ships of the line, with their lower deck guns out, to beat up (not back and fill) from Sheerness to Chatham, and *vice versa;* and we much fear that no pilot would undertake now the responsibility of such a proceeding.

Introduction of chain-cables;

The next improvement to which we shall refer, are the remarkable advantages which have been gained by the extensive use of iron on board ship.

As far back as 1808, Captain Brown, of the navy, proposed the use of iron cables and rigging. There was, however, some difficulty in applying the peculiar welding that was found necessary for the links, so that it was not until 1811 that the cables were fairly tried. Since that time they have gradually been more and more adopted, so much so, that their use may now be considered universal, and certainly no greater boon was ever conferred upon the sea service. The original cost of a chain-cable is about the same as a hempen one, whilst its duration is so much greater that there can be no comparison. The security afforded by it is vastly superior, for it is exposed to none of the deteriorating causes which soon render a hempen cable comparatively so little trustworthy. The alternate wetting and drying which saps the strength of a hempen cable, has little effect on one of iron. The friction against rocks, especially against coral, may fatally damage a cable of hemp in a few minutes; but the same friction, after days of hard use, only polishes a few links of the chain. The introduction of chain-cables has, therefore, whenever the bottom anchored upon is rocky, increased the safety of ships tenfold. Nor does this advantage consist solely in their strength and durability, for they are managed with more facility, occupy much less space, and are coiled away with little trouble; for as they are hove in, they fall in and adjust themselves into a case near the hatchway, from which they are drawn up when wanted. Those who remember the toil and trouble of stowing away a hempen cable into its tier, the wet and dirt, and the number of men required, will not consider these advantages as small ones.

their advantages.

Several adaptations have been found necessary in consequence of the use of chain-cables. The hawse-holes require to be lined with iron, and the bitts cased with the same metal; a new kind of stopper was also required, by which the cable could at any time be prevented from running out, whatever might be the strain upon it. The stopper first adopted, and which answers extremely well, was invented by Captain Brown himself, and is of the nature of a compresser. This stopper is delineated in a figure, and explained in the article CAPSTAN, to which the reader is referred. But the stopper generally used on board men-of-war was invented by Sir Thomas Hardy, and consists of a large swan-necked bar of wrought iron, which embraces the cable as it comes up the hatchway, having one of the ends of the curve fixed to the beams of the lower deck by a powerful bolt, whilst to the other end is attached a tackle, worked on the lower deck, by which the curved stopper can be drawn tight, and the chain pressed so firmly in its embrace against the angle of the hatchway that, however quickly it may be running out, or whatever strain may be brought on it, the cable is at once arrested. For some years after the introduction of chain-cables, hempen messengers were used to heave them in; now chains are adopted, with a considerable saving of expense. The messenger is the endless rope which is taken round the capstan, and being attached to the cable, by what are called nippers, draws in the cable along with it as the capstan is hove round. Nippers are made of rope; iron has been tried, but not, as yet, with much success. But the best arrangement, and that which, we think, will soon be universally adopted, is to dispense with the messenger altogether, and to bring the chain-cable direct to the capstan. (See article CAPSTAN.) No doubt, on board those ships which were first fitted in this way, the chain slipped occasionally, indeed often, when a shackle or swivel came to the capstan; but that defect has now been obviated. When this plan is used, it is necessary to have an addition, called a controller, and which is placed before the bitts, and secures each link of the chain as it is hove in.

One advantage of chain-cables is, that a ship may often lie at single anchor without risk of fouling the anchor. In this case, a good scope of cable ought to be veered out, and the ship backed from her anchor, either by the sails or the power of steam, and if the tides are not very rapid, and if the ground consist of mud, there is no probability of this accident occurring. But if the scope of chain be too short, the tides very strong, and the ground hard, there will be almost the same risk of fouling the anchor as with a hempen cable.

With all these numerous advantages that chain-cables have over hempen ones, there are situations where they cannot be used without modification. For example, anchoring near the land in upwards of forty fathoms water. From such a depth, the great weight of the chain-cable renders the labour of heaving up the anchor very severe; added to which, from the vicinity to the shore, it may be indispensable to get the anchor speedily up, and stowed, so that the ship may be under command. To remedy this evil, which arises from the greater weight of an iron-cable in comparison of one made with hemp, and yet to profit by the security which belongs to rendering invulnerable that part of the cable most exposed to friction by rocks, it has been proposed to bend a length of chain (by seamen called a ganger) to the anchor, and upon the chain to splice a hempen-cable. The outer end of a length of chain being thus shackled to the anchor, the cable may be used in any depth of water, with nearly as much security as if it were made of iron from end to end, with only the inconvenience arising from the additional weight of one length of chain.

Chain rigging.

Chain-slings for the lower yards have been long in use; and, about thirty years ago, chain-topsail-sheets, and chain-ties were introduced, as well as chain-gammoning for the bowsprit, and chain-bobstays, and all have been found, more or less, improvements upon the old plans.

Wire-rope rigging, advantages of.

The great objection to chain-rigging for the lower masts has been its great weight; and, for that reason, it has only been used for those masts of steam-vessels where the hempen rigging would have received injury from the heat coming from the funnel. There is, however, no such objection to rigging made from wire-rope, which, along with all the advantages possessed by chain, is about the same weight and has much of the elasticity of hempen rigging. This wire-rigging is now widely used, and with the most perfect success, for the standing rigging of lower masts. It also, in some respects, answers extremely well for topmast and topgallant-rigging, the only objection being a difficulty of handling it, in the event of its being necessary to shift a mast, or in the event of one being carried away. Her Majesty's ship Terrible, in 1845, was rigged throughout with wire-rope, the lower topmast, topgallant, and royal rigging being all made of it, and there was no complaint of its being

Seamanship.

found inefficient. Besides the great advantage that wire-rigging possesses, of not being affected by the heat and sparks from the funnel, its durability is, at least, three or four times that of common rope, and, when once completely stretched, does not require any further setting up. We may add, that wire-rope can also be used for strapping blocks, and will be found both neat and serviceable.

In men-of-war, the use of iron-ballast, instead of dirty shingle, is also comparatively a recent, but valuable, improvement.

Improvements in the form and manufacturing of anchors.

Soon after the introduction of chain-cables, attention was directed to the defects of the anchor then in common use; but, for a full description of anchors, we must refer our readers to the article under that head; here we shall only briefly allude to the improvement that has taken place. One great defect in the old anchor was the extreme length of the shank, which no doubt was the cause that it so often broke in that part. This accident, after chain-cables were introduced, became more frequent, and was caused by the weight of the chain, which often fell upon the shank and snapped it. Many proposals for a new formation of anchors were made and tried; but, where the old form of anchor was retained, the great principle appears to have been to shorten the shank, but keeping the same weight of iron, thereby increasing the strength of that part. Rodgers, in his anchor, which is now so generally used, adopted that principle, and at the same time made the palm as small as possible. Another species, known by the name of Porter's anchor, improved by Trotman, is now much used in merchant-ships, but has not found much favour with naval officers. This anchor differs from all others, by the flukes being moveable upon a strong pin in the crown of the anchor. Its defect is said to be this: if once it starts from the ground, the facility of bitting again is less than it is with those constructed upon the old plan. In 1852, a committee of naval officers and ship-owners was appointed by the Admiralty to investigate and report upon the properties of different anchors. This committee reported that Trotman's anchor bore the greatest strain without coming home or breaking; but they recommended Lieutenant Rodger's small palmed anchor as the best for all practical purposes.

But anchors are not only now better planned, but by the aid of the powerful steam-hammer, invented by Nasmyth, better made. Formerly, when manual labour only was employed, it often happened, with large anchors, that the iron was not completely welded; that defect is at present unknown. Thus has been added a further security to our ships. The last most important use of iron, to which we shall draw attention, is in a department of seamanship that is of great importance. We allude to the watering of ships. About 1812, iron-tanks were introduced into the navy and mercantile marine, and has very greatly increased the quantity of water which can be carried to sea; whilst the quality has been improved in a manner, of the extent of which no one can form an idea unless he has actually drunk some of the filthy stuff which had been taken out of the wooden casks of bygone days.

Iron-tanks.

An iron-tank of the largest kind at present made for ships of war is called a four-foot cube, though it measures about an inch more in its external dimensions, and occupies sixty-eight cubic feet of space. This area, if entirely filled with water, would contain 424 gallons; but it actually holds 400, which is only twenty-four gallons less than the space would possibly contain.

An increase in the stowage of water is also gained by having tanks made in a form to suit the curve of the ship's hold, or to enter spaces too low to receive cubical tanks.

Introduction of distilled water a great boon.

But the supply of fine wholesome water for steam-ships has been still further increased, by the plan of distilling water on board, as arranged by Sir Thomas Grant, late comptroller of victualling to the navy. By this arrangement, a large ship of the line can distil about two tons an hour by the use of the full power of the apparatus; and, at any time when under steam, can always obtain a sufficient quantity of water from the waste steam without burning extra coals to supply the ship's company's daily use, without trenching upon the stock on board. The plan by which the distilled water is obtained is very simple. The steam is conveyed from a boiler in the engine-room to a condenser placed in the fore-hold. This condenser is placed in water, which is supplied from outside the ship, and conveyed off as it becomes hot. As the steam is condensed into water, it is carried by means of a gutta percha hose into the tanks, where, after it has remained two or three days to be impregnated with atmospheric air, it is ready for use. And we can bear our testimony to all who have not experience of this process, that the water which it produces is of the finest quality, and is fully appreciated by seamen, who justly consider Grant as one of their greatest benefactors—as one of those useful inventors who have added to the comfort, and promoted the health, of their fellow-creatures.

Preserved meats, &c.

Connected with the food of seamen is the discovery of preserving meats, soups, and vegetables, without salt, in cylindrical tin-cases, first devised by M. Appert, a Frenchman, and now in general use at sea. In all her Majesty's ships, these preserved meats have long been supplied to the sick with great advantage. To which has been added for all, rations of chocolate, tea, and sugar, with an increased allowance of the other kinds of provisions, and a decrease of the spirits. This new plan of victualling our seamen has added to their health and sobriety, and leaves little to be desired.

Snow Harris' improvements in lightning-conductors.

In stating these different naval improvements which have characterized the present day, the lightning-conductors of Snow Harris must not be omitted. All who are acquainted with the frequency of disasters at sea are perfectly aware how many are produced by ships being struck by lightning. Impressed with that idea, Snow Harris, as far back as 1822, devised his present plan of conductors, which was fairly tested on board our men-of-war in 1830. They were found to answer their purpose so completely, that all the ships of the navy have long been fitted with these conductors, and gradually they are being adopted in large merchant-ships. And we can state, that there is no instance of a ship being damaged where these conductors were used. Snow Harris's plan differs from all others formerly used in placing his conductor along the different masts, of which it forms, in fact, a component part, and is, therefore, always in its place. In the event of the lightning being about to strike the ship, it comes upon the conductor, and by that means is conveyed through the bottom of the ship without causing the slightest injury. For full details see article ELECTRICITY.

There can be no doubt that, at quite an early period, ships of war had some means of communicating by signals with each other; but it is only within the last few years that this great benefit has been extended to merchant-ships; and at the present time the vessels belonging to the mercantile marine of every nation can, by means of signals, make known their wants, or give intelligence to each other —a boon to the seaman and to the ship-owner that may be easily appreciated.

Various codes of signals.

The codes of signals that are best known in this country, and are of the greatest importance, are comprised in the following list:—

		Year.
1. Admiralty	code	1808
2. Admiralty	„	1816
3. Lynn's	„	1818
4. Squire's	„	1820
5. Admiralty	„	1826
6. Raper's	„	1828
7. Phillipps's	„	1836

Seamanship.

	Year.
8. Rohde's code	1836
9. Admiralty (present code)	——
10. Walker's „	1841
11. Eardley-Wilmot's „	1851
12. Roger's (American) „	1854
13. Reynolds's (French) „	1855
14. Marryatt's (last edition) code	1856
15. Board of Trade (2d edition) code.	1859

Plan of signalizing explained.

There is, however, one general principle adopted in all these codes, whatever be the details, and that is as follows:—A certain number of flags and pendants of different patterns are chosen, and to each is assigned its own name. Some of these flags are called by the different numerals: for instance, one flag is called 1; another 2; and so on. In other systems, the letters of the alphabet are used to denominate the flags. Besides which, other flags or pendants are used for specific purposes: for instance, one pendant is called the interrogative, that is to say, when it is hoisted, it shows that a question is asked, another flag signifies affirmation, another negation, and so on for a variety of other expressions. In the Admiralty signals, this system is carried to a considerable extent; but, in the mercantile codes, the same comprehensiveness is neither attempted nor required, and the number of flags and pendants used is much less. To correspond with the flags, signal-books are formed with sentences or words, which these flags represent. For instance, in using Wilmot's signals, if it were wished to make known the following:—"Boats are in want of ammunition." That sentence would be found in this signal-book opposite to 32; and, therefore, the two flags which express those two numbers must be hoisted. If it were wished to ask the question—"Are the boats in want of ammunition?" then the interrogative pendant would be hoisted over 32.

The Admiralty signals, for the use of men-of-war, are very comprehensive, and require about fifty flags or pendants, and include the following codes:—

First, There is the general signal-book, by which orders for all evolutions are given to the fleet. This also comprises a great deal of routine communication; for instance, one signifies, "Send for fresh beef;" another, "Send for bread;" and so on. The flags that belong to this book are called after the numerals.

Second. The telegraph book includes nearly all the most common words in the English language, and a variety of sentences likely to be useful, a geographical table, and a list of all the ships belonging to her Majesty's navy, with the names of the flags by which each ship is distinguished. The flags and pendants used in this book are called after the letters of the alphabet.

Third. Night-signals: The principle of conveying messages here is the same as in the general signal-book, only the position of lanterns, with or without blue-lights or guns, makes known to the fleet the evolution which the admiral wishes to be performed.

Fourth. Fog-signals: These are, of course, very limited, and can be made only by firing guns; the variation in the signals must be marked by the time elapsed between each report. These signals are confined to a few evolutions, such as giving orders to alter the course, to heave to, anchor, &c. As none of the Admiralty codes are published, we refrain from giving examples.

Each commander of a man-of-war is also furnished with private and secret signals. These are only used to determine whether a ship of war that may be in sight, is a foreigner or not, according as they answer the secret signal; because these signals can only be known to the service.

To the late Captain Marryatt is due the credit of having introduced a code of signals that was practically useful to merchant-vessels, and down to the beginning of 1857 it was the one generally adopted. At that time the Board of Trade gave to the world their work, entitled, *The Commercial Code of Signals for all Nations.* This leaves little to be desired, and is now to be found on board almost all merchant-ships of any size.

This code requires eighteen flags or pendants, which are named from the consonants of the alphabet; and it is so planned that it can show the distinguishing flags of every British merchant-ship. These at present amount to 35,000 registered vessels, and are increasing at about the rate of 1500 per annum; yet, as this system is so arranged as to be able to express the names of 70,000, it will be some years before any enlargement will be required.

The other advantages of this code are as follows:—

1. It is capable of providing for not less than 20,000 distinct signals.

2. Each signal requires at most four flags to be hoisted at the same time.

3. It is so arranged in classes as to admit of the subject being referred to with great facility.

For the further elucidation of these signals, it is necessary to explain, that the Board of Trade publishes annually a list of all British ships registered, with an official number assigned to each. The name and the number never altering, although the port to which the vessel belongs may be changed.

Examples in signalizing.

We shall give, as an example, how three vessels of the same name would make themselves known by this code:—

Flags to be hoisted.	Name.	Official Number.
J Q S B	Mary of Aberdeen	6,901
Q R N L	Mary of Adelaide, South Australia	31,570
S H B P	Mary of Yarmouth, Nova Scotia	37,931

As it may have some interest with our readers, we give, as a specimen of telegraphing, how Nelson's last signal would have been made by Wilmot's code, and also by the code of the board of Trade.

By Wilmot's Code.

Flags to be hoisted.	Signification in the Telegraph book.
Geographical pendant over 793	England
3672	expects-s-ex-ing
5661	every man
8631	to
3208	do-does-done
6435	his
3271	duty-ies-ful-ly-ness.

By the Code of the Board of Trade.

Flags to be hoisted.	Signification in the Telegraph book.
B D P S	England
R F V	expect-s-ing
Q G L	every one
C T G J	will do his duty very well.

Improvements in navigating ships from port to port.

The next most material change for the better, to which we have already shortly alluded, and to which it is our duty now to advert, in speaking of seamanship in the most extensive sense of that word, relates to the manner in which ships are now navigated from port to port, and to and from the most distant parts of the globe, not only with greater celerity, but with greater safety than formerly. No doubt the greater celerity with which voyages are performed is partly due to the better formation of ships (see article SHIP-BUILDING), but the improvements whose tendency have been to add to the security of voyages are mainly due—first, to the superior knowledge of those persons who have charge of ships; secondly, to the improved quality, lower cost, and greatly increased number of scientific instruments and astronomical tables now in the hands of every seamanlike officer; thirdly, to the numbers, accuracy, and cheapness of all the charts of almost all the navigable regions of the world; and lastly, to the more extensive and correct knowledge of the phenomena of the winds, weather, and currents of the ocean. And here we would direct the attention of seamen to the wind and current

Seamanship.

charts of Lieutenant Maury, United States navy, and also to his work, entitled *Explanations and Directions to accompany the above Charts* (eighth edition). Such a magazine of information has never before been opened out to the mariner. In place of giving our own description of the above work, we shall borrow largely from the pages of a popular periodical.

Lieutenant Maury's charts.

"We may expect, as one of the consequences of this publication, that navigation will be divested of some of its delays and dangers. For instance, a sailor, looking at the fog-charts, observes that in one hundred crossings between New York and Liverpool, he may expect to encounter a fog twenty-eight times; that fogs are most frequent in the months of most daylight, and fewest in the darkest months; that certain latitudes are more subject to fogs than others, and hence he can shape his course accordingly. He finds a similar explanation with respect to gales of wind, the seasons when the gales will be favourable, and the reverse; the latitudes where the changes may be looked for, and the course to be taken to make the quickest passages during each month of the year. The scope of the work may be inferred from the fact, that it describes the courses from New York to California, India, Australia, to England and the North of Europe as far as the White Sea, to Africa and the Mediterranean. Mariners know, to their loss and vexation, that crossing the line involves delay. Lieutenant Maury shows how the delay may be avoided, and indicates the best place of crossing the equatorial region for each month of the year.

"Considering the increase of commerce between this country and the United States, and the multiplication of screw-steamers, which make less noise than paddles, we cannot forbear to notice Lieutenant Maury's recommendation for the establishment of what he calls 'steam-lanes' across the Atlantic. Let this recommendation be faithfully followed, and we shall hear but little of collision and loss of life on the sea. Broad as the ocean is, the route taken by steam-ships between this country and the States comprehends a belt of but 300 miles wide. In 1857 there were always fourteen steamers, seven each way, plying within that belt, exclusive of man-of-war steamers; the number is doubtless greater now, whereby the chances of collision are multiplied; and seeing that the number of passengers conveyed in 1857 was 54,700, any practicable measure for diminution of the risk would be worthy of attention. Lieutenant Maury proposes a practicable measure; namely, to set off a lane 20 or 25 miles wide on the northern edge of the belt for steam-ships going west, and a similar lane on the southern edge for those going east, leaving all the middle space, 150 miles in width, for sailing-ships. Were this proposal followed, it is clear that steamers could never meet, though they might overtake each other; and this latter contingency would be an advantage, because, in case of accident, a disabled vessel might be assisted. When once such lanes are properly laid down on the charts, a sailing-ship, if compelled to cross them, would do so as quickly as possible, and would know on what side to look for danger."

Sounding the ocean. Difficulties with the depth of water above 400 fathoms.

Along with this question of currents we must not lose sight of the question of the depths of the ocean. Beyond the depths of three or four hundred fathoms, the usual methods of sounding are very uncertain, and cannot be depended on. When the common lead is used, no shock is communicated at these great depths to those above, and therefore they are not aware when the lead reaches the bottom. Nor when Massey's sounding machine is used does it avail, as that instrument cannot be so constructed as to bear the enormous pressure of so many hundred atmospheres exerted by the vast column of water, which it is necessary to penetrate.

Now, until the Alantic Ocean between England and America was sounded, and the great problem of the depths of water ascertained, it was quite obvious that no attempt could reasonably be made to sink a telegraph cable to the bottom of the ocean, and so join the two countries. To gain the proper soundings, many contrivances were proposed and tried without much success; at length a very simple and ingenious plan was suggested by Lieutenant Brooke, of the United States navy. By his contrivance the sounding line, with an apparatus attached to it, was taken down by a heavy weight, which acted as a sinker; when the bottom was reached, the weight immediately detached itself by a mechanical contrivance, and the apparatus being relieved of its load, was lifted again through the water, bringing up with it, if sufficiently soft, a specimen of the bottom as a proof of its having actually reached solid matter. The contrivance in question consists of a rod, at whose lower end is an inverted cup, provided with a valve, and from the upper end of which is slung a cannon-ball, hollowed to receive the rod. The mode of slinging the ball and suspending the rod is such, that as soon as the bottom of the rod rests upon the bottom of the sea, and the weight is thus removed from the line, the ball is released from its sling, and drops off. The rod, which is of no great weight, can be lifted with the line, and the cup carries up indications of the bottom, and when soft, a portion of the bottom itself.

Plan by which the difficulties were overcome.

This apparatus, with some modifications by Massey, has been adopted by British navigators. The weights to be detached vary from 32 lb. to 96 lb. In the year 1857 her Majesty's steam-vessel Cyclops, Lieutenant Dayman, furnished with these machines, sounded the Atlantic Ocean between Ireland and Newfoundland, and verified the soundings previously ascertained by Lieutenant Berrysman, of the United States steam-vessel Arctic.

It may not be uninteresting to the reader to state, that the greatest depth of water obtained by the Cyclops was nearly 2500 fathoms; at that depth the pressure would be nearly three tons to the square inch. In hauling in the line the friction in lifting it through the water was so great, that before overcoming the inertia and moving the line, it required the whole power of a 12-horse steam-engine, with which the Cyclops had been fitted expressly for the purpose.

We are indebted to the Americans for the first successful attempt to bring to the light of day the secrets of the deep, dark dwelling places, till now, without any relation to human interests, but through which hereafter many of the important events of the world will be communicated. And we have no doubt, that our naval officers will follow up these investigations. and if so, we may hope that in a few years we shall have obtained such accurate knowledge of the bottom of the whole ocean, that the placing of telegraph cables will become a comparatively easy task. For further information upon this subject, the reader is referred to a work entitled, *Deep-Sea Soundings in the North Atlantic Ocean*, by Lieutenant-Commander Joseph Dayman, 1858; also to the fifth article in the *Westminster Review* for October 1859.

Sextant, great value of.

In the first rank of instruments used at sea, we would place the sextant, not the old wooden quadrant, but the brass sextant, as improved by Troughton and Cary, divided to ten seconds, and capable of taking observations with a precision formerly considered inconsistent with the use of a reflecting instrument. The seaman, with such an instrument in his hands, aided by the present nautical almanac, accompanied with either of the excellent treatises on navigation, by Raper or Inman, may determine with exactness the ship's place, in the midst of a boundless ocean, a thousand miles from land. This exactness, within certain appreciable limits, distinguishes the sextant from all other nautical instruments. Its operations are connected with those of the sun, moon, and stars; and by its very construction, its

Seamanship.

principal error may often be ascertained at the very time of making the observation, and allowed for accordingly. The chronometer, which stands next in utility, is essentially a fallible instrument, and although eminently useful in the navigation branch of seamanship, can never be depended upon as the sextant. These two instruments are excellent allies, but neither is sufficient without the other to meet the requirements of modern navigation. A chronometer may, and often does, change its rate, and thus it may deceive; and though the chances of its doing so without detection is much lessened by taking two or three more chronometers in conjunction, still there never can be positive certainty in the result. On the other hand, for all practical purposes, the errors of a sextant lie within the reach of detection and appreciation.

We consider a seaman, who is provided with a modern sextant, with a stand to which it can be fixed, an artificial horizon, and a watch with a compensation balance, or *hack* chronometer, has a portable observatory, by which he can ascertain the rates of his chronometers with the utmost precision, and that without moving them from their places on board. (For full description and use of the sextant, chronometer, and other nautical instruments, see article NAVIGATION, and also CLOCK and WATCH-WORK.)

Chronometer, importance of.

The next in order of importance in the list of nautical instruments, after the sextant, is the chronometer, an instrument to which modern seamanship is indebted for very great service. We are old enough to remember when chronometers were only supplied in the navy to ships about to proceed on voyages expressly scientific, and to those ships which bore an admiral's flag. In the merchant service, the East India Company were the only shipowners who supplied chronometers. Certainly at that time a good chronometer cost from L.100 to L.150, the price is now about L.40, with all the modern improvements; but still, when we consider the number of valuable vessels and lives lost by the want of this instrument, all must agree it was a miserable saving. A great change has now taken place; all men-of-war, and we believe all merchant-vessels employed in the foreign trade, are now furnished with chronometers.

Patent sounding machine and patent log.

There are two important instruments used in navigation, not in the department of nautical astronomy, which have been introduced within the last fifty years, and to which we shall merely allude. We mean the patent sounding machine and the patent log. By the patent sounding machine the seaman is enabled to determine the depth of water up to 60 fathoms, whilst the ship may be still going about 6 knots through the water. By the patent log, if sufficient care be taken, the exact distance that a ship has gone through the water in a given time may be ascertained with accuracy. No doubt, the common log, supposing it carefully hove, and the officer of the watch attentive to any change of the ship's way during the intervals of heaving the log, will give the distance gone with tolerable accuracy, as long as the ship is under sail alone; but when the steam is used, the common log is not to be depended upon; the seaman must then look to his patent log.

Mariner's compass.

Not many years ago, the compasses, on which depended the safety of the ship, on board our men-of-war, were consigned to the charge of the boatswain, and were kept in his store-room, with little more attention given to them than to such articles as twine, canvas, &c.; and in merchant-vessels they even fared worse. At present great pains are taken in the construction of the mariner's compass, and a proper closet is fitted up for their reception. The importance of such care is manifest, when it is recollected that when magnets are placed in proximity to each other, and like poles are laid together, the effect is seriously to impair the magnetic power.

What is called the local deviation of the compass, caused by the iron on board of the ship, is now well understood. Professor Barlow invented a plan of counteracting the effect of the iron of the ship upon the needle, by fixing a circular iron-plate in a vertical position abaft the compass. Professor Airy suggested, to answer the same purpose, placing two large and powerful magnets in the deck, near the compass. But these plans have only partially succeeded, and all men-of-war, and most large merchant-ships, have now their local deviation for each point of the compass, before proceeding to sea, ascertained by actual experiment. A table of these deviations is thus formed, which the seaman uses to correct his courses. The manner of doing this is by taking advantage of a calm day, when the ship is at anchor, and, by means of hawsers, swinging her head round to each point of the compass, noting at the same time the bearings shown by a compass on shore, where there is no local deviation, and by one on board the ship. The differences between the two compasses will show the local deviation, which must be tabulated. (See *Mariner's Compass* in article NAVIGATION; also Johnson *On the Deviation of the Compass*, second edition, 1852.)

Marine barometer and aneroid.

Amongst the scientific instruments which have within this century been introduced into the art of seamanship, the marine barometer occupies a high and important place. Formerly the only kind of barometer used at sea was the mercurial one. This barometer has the advantage, if properly constructed, of being, from its very nature, always correct; but has this disadvantage, when the ship has much motion, its reading off becomes extremely difficult, from the pumping of the mercury up and down the tube. To remedy this defect, about ten years ago, the aneroid, a French invention, was introduced. This instrument is not the least affected by the motion of the ship, and can be read off at all times with the greatest accuracy. It has, however, a defect, which is this. Although it marks with the utmost precision the relative rising and falling, according to the state of the atmosphere, there may be an error in its positive height, which requires correction from time to time. (See article BAROMETER, in which the principle both of the mercurial marine barometer and the aneroid is fully explained.)

Use of barometer at sea.

The use of the barometer at sea consists in giving the seaman information, beforehand, of the changes likely to take place in the direction as well as force of the wind; or, which is sometimes as useful, to let him know, in spite of appearances to the contrary, that there will be no change. But the seaman must recollect that this instrument, as a prognosticator of weather, varies in its degree of utility in different parts of the world. For instance, it is only serviceable in those parts of the tropics which are subject to hurricanes, as it is not affected at all in those regions, except when those great tempests are coming on, and then it suddenly falls about an inch. In this country it often rises, if the wind be easterly, although bad weather may be approaching. On the contrary, off the Cape of Good Hope implicit reliance may be placed upon the rising or falling of the barometer, and the seaman must act accordingly.

Charts.

We must not forget, amongst the modern improvements in seamanship, the great advantage of correct charts. Any one aware of the dangers which really exist, but which are omitted in the old charts, wonders how ships in those times ever escaped destruction; and, on the other hand, he finds the sea so covered with rocks, shoals, and those vague "vigias," as they are called, now known to have no existence, that his admiration is great at the boldness of navigators who could sail on at all during the night.

The government of most civilized countries—and here we are pleased that we are enabled to say that the English government has led the way—have taken up this matter in earnest, and sent their surveyors abroad; the result has been that the world has been put in possession of charts of all those harbours, coasts, and seas which are most fre-

quented. At the same time much remains to be done; but if the present progress in marine surveying be continued for a few more years, so accurate will be the construction of charts, that ships duly provided with nautical instruments will seldom incur the danger of running on shore, except by stress of weather, or experience any difficulty in finding safe passages amongst sand-banks, coral reefs, or any other description of submarine dangers, the terror of old navigators.

It would lead us beyond our limits were we to go into further detail, in order to point out the various minor improvements which have been introduced into the practice of navigation. For the same reason, we must omit all mention of the improvements that have taken place in the rope, canvas, rigging, and fitting out of ships.

Numerous wrecks of British merchant-vessels.

But with all this that is so favourable, there is still a dark side to the question. By official returns it appears that, in spite of all these improvements, there are annually lost upon our own coasts, upon an average of seven years, about 1200 British merchant-vessels. The number of British seamen drowned, excluding fishermen, and those wrecked in foreign voyages, taking the same average, amount to 760. It also appears that a large proportion of these wrecks arises from causes that might have been easily avoided. The causes are, chiefly going to sea with rotten masts and sails, either bad or no charts on board, not heaving the lead, or not taking an observation, and the ignorance or drunkenness of those in charge of the navigation of the vessel. Surely such a reckless destruction of life and property conveys a very urgent lesson upon all persons in authority, that they should not only foster every improvement connected with our mercantile naval service, but that they should also enforce upon all who are concerned the responsibility they incur to make these experiments effectual.

There are still two topics remaining on which we must be allowed to touch before bringing this article to a close. One is the importance of discipline on board ships, and the amelioration in the moral character of all the seamen of the country. The other is the change which has taken place in the armaments of ships of war, and the alterations and improvements in the training of our seamen, which are now required in consequence of this change. As both of these points have become part and parcel of the seamanship upon which our prosperity as a nation mainly depends, we cannot on this occasion pass them over in silence.

Discipline, importance of.

There can be no good seamanship without discipline, for it is as essential to the correct working of a ship that there should be a clearly understood subordination established on board, as it is to the correct going of a chronometer that all the wheels and pinions be made to fit, and be so placed as to work properly into one another.

This well-defined system of discipline and organization is doubly necessary in the navy. In that service large bodies of men are thrown together, and must be governed by the strict application of martial law, which is essentially peremptory in its action, and requires immediate obedience. We are happy to be able to state, that within the last few years the practical and working system has been, that whilst a rigid law must always be kept up, yet the main dependence for bettering the habits and improving our seamen has been based more decidedly on religious and moral training. To this training has been added the plan of giving extra pay for good conduct, and providing pleasant reading for our ships' companies. We are old enough to remember the time when coercion was considered the only means of having an evolution quickly performed. Now, another element is introduced, namely, emulation; and the consequences are these, that in performing evolutions in the fleet, the officers oftentimes are not only spared the necessity of urging their seamen and marines to exertion, but actually have to restrain their ardour to prevent accidents.

All ships commanded by a captain have now chaplains appointed, joined to which are also the seaman's schoolmaster, to teach the boys, and those of the ship's company who wish to avail themselves of his instructions; and we can also add, as we have already stated, a small library of books is now always supplied, including a sufficiency of Bibles, Testaments, prayer-books, and religious tracts.

Religious instruction.

Something has been done also for our merchant-sailor, but much yet remains to be done for him. Cut off as so many of these seamen are from all religious instruction for a great portion of their lives, it is much to be desired that more active exertions were made at our large seaports to bring a knowledge of Christianity to meet their wants. All that is done to raise the seaman's character, and to give him habits of sobriety, is so much added to the prosperity of the country.

Merchant-seamen not good riggers.

It is now, we are sorry to say, almost the universal practice, for a merchant-ship to be fitted out and rigged by those hired for the express purpose; the crew not going on board until the vessel is on the very point of sailing on her voyage. Following that plan, as soon as the ship returns, the crew are landed. The effect has been, that a large proportion of merchant-sailors at the present time are unable to rig a ship. Now, as no seaman who is not a competent rigger can expect to rise above an able seaman in the navy, that is one reason why it has become very rare for any person arrived at full manhood, and who has been brought up in a merchant-ship, to enter the royal navy. He sees his inferiority to the regular man-of-war sailor, and the two professions are in consequence now almost completely disjoined.

Improved method of throwing shells.

About the year 1827, the maritime nations of the world commenced gradually increasing the size of their ships of war, and adding to the weight of metal of the great guns. Soon after this period the use of shells, fired horizontally, was introduced. The shells are not, as formerly, fired from mortars only, but are thrown from the long guns used in ordinary warfare, and treated the same as round-shot. Within the last few years the quantity of shells supplied to each ship has so much increased that a large proportion is now allowed to each gun on board our men-of-war, and no doubt will now become the principal weapon that will decide the fate of naval warfare. This change in the armaments of our ships required a superior training to be given to both our officers and seamen. An express gunnery department was established for the purpose of instruction, and the manner in which it has been carried out in our ships of war has produced a marked effect in the knowledge of gunnery in the seamen throughout the fleet. We have no hesitation in saying, that a large proportion of the regular men-of-war sailors of the present day are the most perfect artillerymen that the world has ever seen. Such being the case, without a long previous training, it is quite evident, that in the event of a battle, the uninstructed merchant-sailor hastily joining a man-of-war would be of little more service than a landsman, indeed not so much as a landsman who had received any former training at the great guns. It must also be recollected, that the next naval engagement will be fought by ships propelled by the screw, and that the sails will be furled. It will then be found, that the great battle which has to decide the fate of empires will not be so dependent on seamanship as heretofore. It will hang upon the conjoined action of men well trained and well disciplined, but the necessity still remaining of fighting under the direction of able officers, and stimulated by the influence of national sentiment.

Notwithstanding the changes which have taken place within the recollection of many now alive, we cannot foresee all that modern science, skill, and enterprise may effect. A recent invention in the construction of a new species of war-vessel, with sides plated with metal, and carrying the maximum of steam-power with the minimum size of sails,

may produce changes even greater than those to which we have already referred, and may cause a still greater demand for men well conversant in artillery practice; a practice which in these vessels will be of more importance than skill in seamanship.

Further changes probable.

Further changes seem also to be at hand in the mercantile navy. By the introduction of such immense vessels as the Great Eastern, provided with such powerful machinery, it is obvious that the sails cannot hold the same place which they have done in smaller vessels; and whether this may ultimately diminish the demand for seamen generally, or in some degree change the character of seamanship itself, is a problem which we must leave to time and future experience for solution.

The following are approved works on seamanship in English:—Falconer's *Marine Dictionary;* Darcy Lever's *Seamanship;* Griffith's *Practical Hints;* Captain Glassock's *Naval Officers' Manual;* Lieutenant Fordyce's *Outlines of Naval Routine; Professional Recollections on Seamanship*, by Captain F. Liardet; Clerk's *Naval Tactics; Naval Warfare with Steam*, by Sir Howard Douglas, 1858. Useful hints may be derived from James's *Naval History*, and also from the chapter on "Making the Land" in Raper's *Navigation; The Seaman's Manual*, by R. H. Dana, junr., 8th ed., 1859; *A Manual of Naval Tactics*, by James H. Ward, commander U.S. navy, 1859; these two last are by American authors. In French, Pere Hoste and Grenier; also, *Reglement sur le service interieur à bord des Batiments de la Flotte.* This work has been translated into English by Captain Phillimore. *Decret sur l'organisation du personnel des equipages de la flotte; Tactique Navale*, 1857. (W. R.)

SEBASTIAN, Dom. See Portugal.

SEBASTIANO, an eminent Venetian painter, whose family name was Luciano, frequently called Fra Sebastiano del Piombo, from his office of keeper of the Papal signet, was born at Venice in 1485. His first profession was music, in which he attained to great excellence in his youth. Conceiving early a taste for the painter's life, he went to Bellini, who was then an old man, and learned from him the first rudiments of his art. Sebastiano next attached himself to Giorgione, with whom he remained till he had mastered the manner of that artist. His first painting of any note, executed for the church of San Giovanni Crisostomo, in Venice, gives abundant evidence of this, as it has been frequently mistaken for the work of Giorgione. Induced by the representations of Agostino Chigi, merchant at Siena, to go to Rome, Sebastiano on arriving there immediately set to work, and produced some very excellent paintings in the Venetian manner, which were much esteemed by the art-patrons of the capital. Raffaëlle was now rising into great fame as a painter, and, according to Vasari's account of it, Michel Angelo, jealous of his illustrious rival, set up Sebastiano as a fit competitor to the famous artist of Urbino. The whole story is doubtless a fabrication, arising probably from the fact of Michel Angelo having contracted a liking for the exquisite judgment and beautiful colouring of Sebastiano, and from his having undertaken, on that account, to aid him in the art of designing, of which he is universally recognised to be the chief. Be this as it may, it is beyond doubt that Sebastiano simply painted after the designs of Michel Angelo for a number of years, and upon these paintings his reputation as a historical painter chiefly rests. The exquisite beauty of the colouring in those paintings, combined with their rich grandeur of design, if they did not rival Raffaëlle's divine productions, at least excited a great interest in the art-lovers of Rome, and have not ceased since to be the objects of universal applause. The pieces in question were a "Pieta" for the church of the Conventuale at Viterbo; the "Transfiguration" and "Flagellation," in San Pietro in Montorio; and the "Raising of Lazarus," which is esteemed his masterpiece. On the death of Raffaëlle, Sebastiano was accorded the first place in painting, and he continued in his provokingly sluggish manner to design and paint as the fit seized him. Vasari says his peculiar walk was portrait-painting; and assigns as evidence of the statement the beautiful representations of Marcantonio Colonna, Vittoria Colonna, Ferdinando, Marquis of Pescara, Pope Adrian VI., San Micheli, Pope Clement VII., and Anton Francesco degli Albizzi. This last portrait has astonished all eyes who have looked on it. The head and hands are "a sort of miracle," and the portrait did not seem to be painted but living. "No one has ever equalled," says Vasari, "the delicacy and excellence of this work." Perhaps the most striking portrait executed by this artist is that of Giulia Gonzaga. It is declared by Vasari to be "a most divine one." This picture, and the "Raising of Lazarus," are now in the National Gallery, London. Sebastiano was greatly patronized by Pope Clement VII., who conferred upon him the office of keeper of the Papal signet. This post induced him to assume the monk's habit, and to adopt the title of Fra or Frate del Piombo. Vasari complains heavily against the painter, in his garrulous way, for neglecting to prosecute his sublime art now that he had "sufficiency to live on." Sebastiano was fond of ease, as other men of genius have been, both before and since, which induced him to crack pleasant jokes on those who made themselves busy in upbraiding him for his sloth. "I think," he would say, in his satirical tone, "I think, indeed, that if I live much longer I shall find that everything has been painted which it is possible to paint; and since these good people are doing so much, it is upon the whole well that there is one who is content to do nothing, to the end that they may have all the more to do." Vasari adds, however, "a better or more agreeable companion than himself, of a truth, there never lived." Fra Sebastiano del Piombo died at Rome in 1547, aged sixty-two years.

SEBASTOPOL, or Sevastopol. An account of this place, as it was before its siege by the allied armies in 1854–5, is given in the article Crimea; and a narrative of that siege in the historical portion of the article Russia. The whole of the city south of the harbour was laid in ruins, with the exception of parts of the cathedral, and of some other buildings. These have since been restored, and the whole city is being rebuilt after a new plan. It was consecrated in July 1856 by the Archbishop of Cherson and Taurida; and, in January 1857, 380 houses had been built or restored. The population, according to the Russian Almanac for 1859, is 6213.

SEBENICO, a town of the Austrian empire, in the kingdom of Dalmatia, circle and 42 miles S.E. of Zara, on a bay of the same name, at the mouth of the Kirka. It is built in the form of an amphitheatre, rising up the side of a hill from the sea to the summit, which is occupied by two forts. Old walls surround the town; and another fort, new and strong, commands the entrance of the bay. The most conspicuous building is the cathedral, in the Lombardic style, which has a very grand interior and a lofty dome. There is here also an old Venetian town-hall, several churches, and convents. Wine and oil are obtained in abundance in the surrounding country. Distilling is carried on in the town; and there is a considerable trade. In 1855 there entered the port 1704 vessels, tonnage 78,342; and there cleared 1542, tonnage 76,159. Pop. 5500.

SECANT. See Geometry and Trigonometry.

SECEDERS. See Presbyterianism.

SE-CHUEN, or Szu-Chuan, the largest of the pro-

vinces into which China is divided, lying between N. Lat. 26. and 33., E. Long. 101. and 110.; bounded on the N. by the provinces of Kau-soo and Sheu-se, E. by those of Hou-nan and Hou-pe, S. by those of Kwi-choo and Yan-nan, and W. by Tibet. Area, 167,055 square miles. Almost the whole of this province, except a plain of some size near the centre, is rugged and mountainous. The immense river Yang-tse-kiang traverses the country in a tortuous course, from S.W. to N.E., and receives many of its chief affluents here. The productions of the province are silk, sugar, musk, rhubarb, china root, iron, tin, lead, salt, and horses. Pop. (1812) 21,435,678, (1843) 22,000,000.

SECKENDORF, Veit Ludwig von, a statesman, theologian, and historian of Germany, was born at Herzogenaurach, near Erlangen, on the 20th December 1626. He was sprung from a noble family of Franconia, and his father, who had held a good position in the army of Gustavus Adolphus during the Thirty Years' War, was executed by a Swedish court-martial in 1642. The lad began his studies at the gymnasium of Coburg in 1638, and was subsequently removed to the gymnasium of Gotha, at the request of the Duke of Gotha, who, after his father's death, showed him great kindness. At the University of Strasburg he applied himself with great zeal to nearly all the exercises of the place; and, on the completion of his studies, he was taken into the service of his patron, where he rose through the various grades of office, till, in 1664, he was made privy councillor and chancellor. Seckendorf took an important share in every educational and in every religious movement which agitated the duke's dominions during the time he held office under him. For some private reason or other he left the duke's service in 1664, and entered that of Moritz, duke of Zeit, where he was appointed to his former offices. Here Seckendorf exhibited the same popular qualities which had hitherto characterized him; but by some mischance he became involved in some squabbles with the clergy, which induced him, on the duke's death, to resign. He retired to his country-house of Meuselwitz, near Altenburg. Having accepted an invitation from Frederic, elector of Brandenburg, in 1691, to enter his services as privy councillor at Berlin, and chancellor of the University of Halle, Seckendorf died the following year.

The principal works of Seckendorf are as follows:—*Deutscher Fürstenstaat*, Gotha, 1665; *Compendium Historiæ Ecclesiasticæ*, Leipzig, 1666; *Christenstaat*, Leipzig, 1685; *Jus Publicum Romanorum*, Frankfurt, 1686; *Commentarius Historicus et Apologeticus de Lutheranismo*, Frankfurt, 1692. The Life of Seckendorf was written by Schreber, Leipzig, 1734.

SECKER, Thomas, Archbishop of Canterbury, and the friend of Bishop Butler and of Bishop Berkeley, was born at the village of Sibthorn, in Nottinghamshire, in 1693. Designed originally for the dissenting church, of which his parents were members, he laboured with great assiduity to perfect himself in all liberal arts. He made uncommon progress in every study to which he directed his attention, and by the time he had reached the age of twenty-three, he was one of the best read men of his years in England. His mind being in suspense regarding some of the speculative doctrines of Christianity, he resolved in 1716 to study medicine. With this intention he went to London and Paris; but he had not long resided abroad when an offer came to him from Joseph Butler, whose school-fellow he had been, and who was now preacher at the Rolls, to enter the Church of England. Secker, after some deliberation, complied with his friend's proposal, and he arrived in England in August 1720. He went to Leyden next year and took his degree of M.D., and on his return was made Bachelor of Arts of Exeter College, Oxford. Secker now spent a considerable part of his time in London, where he became acquainted with Dr Clarke and with Bishop Berkeley. Bishop Talbot being appointed to the see of Durham in 1726, Secker accompanied him in 1723 and received the rectorship of Houghton-le-Spring. In 1725–26, Butler published his celebrated *Sermons*, and Secker seems to have revised them previous to publication. In 1727 he exchanged his situation for that of prebendary of Durham and rector of Ryton, and in 1732 he was made chaplain to the king. Secker was now rising rapidly into notice as a preacher and a divine, and in 1733 he was transferred to St James's as rector. He went to Oxford the same year and took his degree of LL.D., and two years afterwards he found himself Bishop of Bristol. In 1737 he was chosen Bishop of Oxford on the promotion of the learned Dr Potter to Canterbury. In 1750 he was installed dean of St Paul's, and eight years afterwards he was elevated to the see of Canterbury. From this period Archbishop Secker resided constantly in his palace at Lambeth. He had been afflicted with gout for many years, which now proved almost intolerable. It threw him into a fever, of which he died on the 3d of August 1768.

SECT, according to some from the Latin *seco*, I cut; and according to others from *sequor*, I follow; is a word of common use, denoting those who follow some teacher or leader, or who unite in holding sentiments different from the majority. It is employed to characterize religious, philosophic, political, and literary bodies, but the term is generally limited to the first of these.

SECTOR, is a part of a circle comprehended between two radii and an arc of the circle. Sector is also a mathematical instrument, of use in finding the proportion between quantities of the same kind; as between lines and lines, surfaces and surfaces, &c., whence the French call it the *compass of proportion*. The great advantage of the sector above the common scales is, that it is made so as to fit all radii, and all scales. By the lines of chords, sines, &c., upon the sector, we have lines of chords, sines, &c., to any radius between the length and breadth of the sector when open. The sector is supposed to have been invented by Guido Baldo, or Ubaldo, about the year 1568. The first printed account of it was in 1584, by Gaspar Mordente, at Antwerp, who says that his brother, Fabricius Mordente, invented it in 1554. Treatises on its use have been written by Daniel Specle at Strasburg, in 1589; also by Thomas Hood at London, in 1598; and by Lewin Hulse at Frankfort-on-the-Maine, in 1603, who says that it was invented long before by Justus Byrgius. But the honour of the invention was claimed by Galileo, who wrote on its use in 1607, and by Balthasar Capra of Milan. There are also treatises on it by our countrymen Gunter, Forster, and others. Before the invention of logarithms, practical men were more easily contented with approximate solutions than they are at present. Now, however, the sector is not much used, although it is commonly reckoned one of a complete set of mathematical instruments.

For treatises on its use, see Bion on *Mathematical Instruments*, translated by Stone; Robertson's *Treatise on Mathematical Instruments*; and Adam's *Geometrical Essays*.

Any one possessing a sector will easily understand its theory and use from the 14th problem of the fifth section of our treatise on Geometry, where it is taught how to find a fourth proportional to three given lines.

The Astronomical Sector, or Equatorial Sector, is an instrument for taking the difference of right ascensions and declinations of such stars as, on account of their great difference of declinations, will not pass through a fixed telescope.

The Zenith Sector is an instrument employed in extensive trigonometrical surveys. Its use is to determine with great accuracy the zenith distances of stars whose declinations differ but little from the latitude of an observer.

SECUNDERABAD, a town of India, in the Nizam's

territory, 6 miles N. of Hyderabad, and 398 N.W. of Madras. It stands on the N.E. side of an artificial lake called Hoosain Sagur, 3 miles in length by 2 in breadth, and in the midst of isolated granite hills and rocks. It consists of a British military cantonment, regularly laid out, and a native town, with crooked, narrow, and irregular streets. In the former part there are, besides commodious barracks, several bazaars, a large and handsome church, and an hospital. Pop. 34,357.

SECUNDUS, JOANNES NICOLAIUS, an elegant writer of Latin poetry, was born at the Hague in the year 1511. His descent was from an ancient and honourable family in the Netherlands; and his father, Nicolas Everts, or Everardus, who was born in the neighbourhood of Middleburg, seems to have been high in the favour of the Emperor Charles V. On what account our author was called Secundus is not known. It could not be from the order of his birth, for he was the youngest son. Perhaps the name was not given him till he became eminent; and then, according to the fashion of the age, it might have arisen from some pun, such as his being *Poetarum nemini Secundus*. Poetry, however, was by no means the profession which his father wished him to follow. He intended him for the law, and when he could no longer direct his studies himself, placed him under the care of Jacobus Valeardus; but it does not appear that Secundus devoted much of his time to legal pursuits. Poetry, and the sister arts of painting and sculpture, had engaged his mind at a very early period. Secundus, being determined to comply as far as possible with the wishes of his father, quitted Mechelen and went to France. At Bourges he studied the civil law under the celebrated Andreas Alciatus. Having spent a year under this eminent professor, and taken his degrees, Secundus returned to Mechelen, where he remained only a very few months. In 1533 he went into Spain, with warm recommendations to the Count of Nassau and other persons of high rank; and soon afterwards he became secretary to the Cardinal-Archbishop of Toledo, in a department of business which required no other qualifications than those he possessed in a very eminent degree, a facility in writing with elegance the Latin language. It was during his residence with this cardinal that he wrote his *Basia*, a series of wanton poems, of which the fifth, seventh, and ninth *carmina* of Catullus seem to have given the hint. Secundus was not, however, a servile imitator of Catullus. His expressions seem to be borrowed rather from Tibullus and Propertius; and in the warmth of his descriptions he surpasses everything that has been written on similar subjects by Catullus, Tibullus, Propertius, C. Gallus, Ovid, or Horace. In 1535 he accompanied the Emperor Charles V. to the siege of Tunis, but gained few laurels as a soldier. Having now quitted the service of the Archbishop of Toledo, Secundus was employed in the same office of secretary by the Bishop of Utrecht; and so much had he hitherto distinguished himself by the classical elegance of his compositions, that he was soon called upon to fill the important post of private Latin secretary to the emperor, who was then in Italy. This was the most honourable office to which our author was ever appointed; but before he could enter upon it, death put a stop to his career of glory. Having arrived at Saint Amand, in Tournay, he was, upon the 8th of October 1536, cut off by a violent fever, in the very flower of his age, not having quite completed his twenty-fifth year. He was interred in the church of the Benedictines, of which his patron the bishop was abbot; and his near relations erected to his memory a marble monument, with a plain Latin inscription.

The works of Secundus have gone through several editions, of which the best and most copious is that of Scriverius, Leyden, 1631. It consists of *Julia*, eleg. lib. i.; *Amores*, eleg. lib. ii.; *Ad Diversos*, eleg. lib. iii.; *Basia*, styled by the editor *incomparabilis et divinus prorsus liber; Epigrammata: Odarum liber unus; Epistolarum liber unus; Epistolarum liber alter, heroico carmine scriptus; Funerum liber unus; Sylvæ et Carminum fragmenta; Poemata nonnulla fratrum; Itineraria Secundi tria; Epistolæ totidem, soluta oratione.* They are prefixed by recommendatory notices from many eminent men, particularly Lelius Greg. Gyraldus, the elder Scaliger, and Theodore Beza.

SECUTORES. See GLADIATORS.

SÉDAN, a town of France, capital of an arrondissement in the department of Ardennes, on the right bank of the Meuse, 160 miles N.E. of Paris. It stands on uneven ground, and is surrounded by walls, moats, and other fortifications, so as to be an important place for the defence of France on the side of Belgium. The castle, which stands on a hill to the S.E. of the town, contains an arsenal, and near this and in other parts there are three large barracks. The streets are mostly broad and clean, and the houses well built of stone. There are several fine public walks and fountains; and the chief buildings are Roman Catholic and Protestant churches, a theatre, public library, and hospital. Sédan is an important manufacturing town, its principal productions being broad-cloth and other woollen fabrics. Linen, leather, hosiery, hardware, firearms, &c., are also made here. The town has given its name to the vehicles called sedans, or sedan-chairs, which were first made here. They were introduced into this country in 1581, and came into general use about 1649. An active trade is carried on in corn, cattle, hemp, flax, and manufactured goods. The town has law-courts, a chamber of agriculture, and a college. The celebrated Marshal Turenne was a native of this place. Pop. (1856) 13,304.

SEDBERGH, a market-town of England, in the West Riding of Yorkshire, in a secluded vale enclosed by hills, 64 miles N.W. of York. It consists chiefly of one street, lined with stone-houses, and has an ancient parish church; Independent, Wesleyan, and Quaker places of worship; a free grammar school, national school, and poorhouse. Cotton and woollen fabrics are manufactured here. Pop. of the parish, 4574; of the town, about 2000.

SEDGEFIELD, a market-town of England, in the county and 11 miles S.E. of Durham. It is an old-fashioned town, built on a hill, with a large square containing a market cross. The parish church is cruciform, in the early English style, and has some interesting monuments. There are also places of worship for Wesleyans and Roman Catholics, a free grammar school, alms-houses, &c. Many of the people are employed in shoemaking. Pop. of the parish, 2192.

SEDITION, among civilians, is used for a fractious commotion of the people, or an assembly of a number of citizens without lawful authority, tending to disturb the peace and order of society. This offence is of different kinds. Some seditions more immediately threaten the supreme power, and the subversion of the present constitution of the state; others tend only towards the redress of private grievances. Among the Romans, therefore, it was variously punished, according as its end and tendency threatened greater mischief. (See lib. i. *Cod. de Seditiosis*, and *Mat. de Crimin.* lib. ii. n. 5, *De Læsa Majestate.*) In the punishment, the authors and ring-leaders were justly distinguished from those who, with less wicked intention, joined and made part of the multitude.

The same distinction holds in the law of England and in that of Scotland. Some kinds of sedition in England amount to high treason, and come within the statute 25 Edward III. as levying war against the king. And several seditions are mentioned in the Scotch acts of parliament as treasonable (Bayne's *Crim. Law of Scotland*, p. 33, 34). The

Sedley || Seetzen.

law of Scotland makes riotous and tumultuous assemblies a species of sedition. But the law there, as well as in England, is now chiefly regulated by the Riot Act, made 1 Geo. I.; only it is to be observed, that the proper officers in Scotland to make the proclamation thereby enacted are sheriffs, stewards, and bailies of regalities, or their deputies; magistrates of royal burghs, and all other inferior judges and magistrates; high and petty constables or other officers of the peace, in any county, stewartry, city, or town. In that part of the island, the punishment of the offence is anything short of death which the judges, in their discretion, may appoint.

SEDLEY, Sir Charles, an English poet and wit, the son of Sir John Sedley of Aylesford, in Kent, was born about the year 1639. At the Restoration he came to London to join the general jubilee, and was so much admired that he became a kind of oracle among the poets, which made King Charles tell him, that nature had given him a patent to be Apollo's viceroy. The productions of his pen were some plays, and several tender amorous poems, in which the softness of the verses was so exquisite as to be called by the Duke of Buckingham Sedley's witchcraft. Less pleasing opinions, however, have been expressed by others. "There were no marks of genius or true poetry to be descried, say the authors of the *Biographia Britannica;* "the art wholly consisted in raising loose thoughts and lewd desires, without giving any alarm; and so the poison worked gently and irresistibly. Our author, we may be sure, did not escape the infection of his own art, or rather was first tainted himself before he spread the infection to others." Whilst he grew in reputation for wit and in favour with the king, he became poor and debauched; his estate was impaired, and his morals were corrupted. One of his frolics, however, being followed by an indictment and a heavy fine, Sir Charles took a more serious turn, applied himself to business, and became a member of parliament, in which he was a frequent speaker. We find him in the House of Commons in the reign of James II., whose attempts upon the constitution he vigorously withstood; and he was very active in bringing about the Revolution. This was thought more extraordinary, as he had received favours from James. But that prince had taken a fancy to Sir Charles's daughter, though it seems she was not very handsome, and, in consequence of his intrigues with her, he created Miss Sedley Countess of Dorchester. This honour, so far from pleasing, greatly shocked Sir Charles. A witty saying of Sedley's on this occasion, is recorded. "I hate ingratitude," said Sir Charles; and "therefore, as the king has made my daughter a countess, I will endeavour to make his daughter a queen;" meaning the Princess Mary, married to the Prince of Orange, who dispossessed James of the throne at the Revolution. He lived till the beginning of Queen Anne's reign, and his works were printed in two volumes 8vo, 1719.

SEELAND. See Zealand.

SÉES, a town of France, in the department of Orne, on the Orne, 13 miles N. by E. of Alençon. Its most conspicuous building is the cathedral, which is one of the finest in Lower Normandy, a building in the Gothic style of the thirteenth and fourteenth centuries. Sées has also an episcopal palace, several schools, and cotton factories. Pop. 5205.

SEETZEN, Ulrich Jaspar, a German traveller of some note, was born near Jever, on the 30th January 1767. He received an excellent education, first at Jever and subsequently at the University of Göttingen. Here he studied medicine, the natural sciences, agriculture, and political economy. He formed an acquaintance with Alexander Von Humboldt, who became afterwards such a distinguished traveller. Seetzen likewise gained the friendship of Heyne, Gatterer, Eichhorn, and Blumenbach, who encouraged him in his design of making the field of his enterprise Asia and Africa. He was recommended by Blumenbach to the notice of Baron Von Zach, who subsequently introduced him to the Duke of Gotha, by whom he was fitted out for his future travels, and had an annual sum allotted him for the prosecution of them. Seetzen accordingly set out on the 13th June 1802, with the intention of gathering all available information respecting the mathematical and physical sciences, the arts, statistics, geography, and archæology. He directed his route by Vienna and Constantinople, at which cities he spent nearly a year in active preparation for his coming expedition. Having made his way as far as Haleb in the end of 1803, he there spent fifteen months in the study of Arabic. From Haleb he proceeded to Damascus, through Syria and Palestine, until he gained the deserts of Arabia. Thence proceeding northward he visited the region of Lebanon, and directed his course to the country east of the Jordan. We find him at Acre towards the end of 1806, whence he made excursions into Palestine, and finally crossed the isthmus of Suez and entered Egypt, where he remained for the next two years. Here he continued to collect, with his accustomed industry, manuscripts, archæological, mineralogical, botanical, and zoological specimens for the museum of Gotha. Having externally espoused the Mohammedan faith, he next thought of visiting those places in Arabia to which Mohammedans alone have access. After various unsuccessful attempts, he at last succeeded in gaining Mecca and Medinah, where he spent some time in executing drawings and plans. Early in the year 1810, he set out for Mocha. A letter, dated November 17th of the same year, and addressed to Lindenau of Gotha, was the last authentic news received of this enterprising traveller. Mr Buckinghim, in a letter to Von Hammer, dated from Mocha 1815, said that Seetzen had died suddenly at Taes in 1811, and it was currently reported that the unfortunate traveller had been removed by poison by order of the Imâm of Sana. Nearly the whole of Seetzen's diary and collections were subsequently recovered, and were placed in the hands of Professor Kruse of Dorpat with a view to their publication.

Segesta.

SEGESTA, by Attic writers called Egesta, an ancient city of Sicily, stood at the head of a deep bay on the north coast near the western extremity of the island, 6 miles from the sea, and 34 W. of Panormus. It seems to have occupied the summit of a small hill overlooking a ravine, through which flowed a river. The situation is very bleak and exposed. Laying aside the traditionary legends which ascribe the foundation of the city to emigrants from Troy, we may ascertain, on more certain grounds, that it was neither founded by the natives of Sicily nor by Greek colonists; although from intercourse with the Greek cities in the vicinity, it early acquired a civilized character, quite different from the barbarous natives. Segesta was for a long period engaged in almost perpetual conflicts with Selinus, on the south coast of the island. These petty feuds would have been little worthy of mention, had they not led indirectly to a most important event in Greek history, the fall of the Athenian power in the Peloponnesian War. For the event that more than any other led to the fatal issue of that war was the disastrous result of the great Athenian expedition to Sicily (416–413 B.C.), and that was undertaken at the request of the Segestans, when their enemies of Selinus were hard pressing them, having obtained the assistance of Syracuse. After the Athenian fleet and army had been annihilated in the fruitless siege of Syracuse, the Segestans, unable to contend single-handed with their foes, made an alliance with Carthage. The troops of that nation speedily landed in Sicily in 410 B.C.; took and destroyed Selinus and Himera, and established firmly the power of their country in the west of Sicily. For a long time Segesta adhered firmly to the Carthaginian interest,

and resisted a siege by Dionysius of Syracuse in 397 B.C., while, though it was taken ninety years after by Agathocles, it afterwards regained its liberty. But, on the first breaking out of war between Carthage and Rome 264 B C., it was one of the cities that earliest deserted the cause of the former. Hence it was always treated with especial favour by the Romans. No important event in subsequent history brings into notice the name of Segesta; it gradually fell into decay, and was finally abandoned on account of the ravages of the Saracens. Except some vestiges of the walls, the only remains now to be seen of the city are a temple and a theatre.

SEGMENT of a circle, is that part of the circle which is contained between a chord and an arc.

SEGNI, Bernardo, a Florentine historian, was born at Florence about the end of the fifteenth century. He studied law at Padua, pursued merchandise at Aquila, returned to Florence, where he was employed in state affairs by Duke Cosimo I. Segni translated the Rhetoric, Ethic, Politic, and the treatise on the Soul, of Aristotle into Italian, and subsequently engaged in a *Storie Fiorentine dall' anno* 1527 *all' anno* 1555. As he kept his history secret during his life, it was remarkable for the conscientious spirit in which it was written, and Segni will go down to posterity as one of the very best writers which Italy has produced. His history is decidedly superior to those of Varchi, Nardi, and Nerli, who have treated of nearly the same period. Segni died in 1559.

SEGO, the chief town of the kingdom of Bambarra, in Western Africa, on both sides of the Niger or Joliba; N. Lat. 13. 5., W. Long. 5. It consists of four separate parts, unwalled, two on each side of the river. The houses are, in general, built of clay, square and flat roofed. There are a palace and numerous mosques. Pop. 30,000.

SEGORBE, a town of Spain, Valencia, province of Castellon-de-la-Plana, at the foot of a valley between two hills, above the Palancia, in a rich country laid out chiefly in gardens, 29 miles N.N.W. of Valencia. It has ancient walls; and on the summit of the hill above stands a castle. There are broad streets, several squares, and many fountains. The principal building is the cathedral, which contains some good paintings, but is not very remarkable for its architecture. Segorbe has several other churches, an episcopal palace, a large court-house, a theatre, various schools, hospitals, convents, &c. Earthenware, paper, starch, brandy, &c., are made here; marble is quarried in the vicinity, and two fairs are held annually. Pop. 6005.

SEGOVIA, a province of Spain, in Old Castile, bounded on the N. and N.E. by those of Burgos and Soria, S.E. by those of Guadalajara and Madrid, S.W. by that of Avila, and N.W. by that of Valladolid. Area, 2670 square miles. The surface of the country is much varied; it belongs to the central table-land of Spain, and has a considerable extent of level plains, especially in the central and northern portions. Along the south-eastern boundary extend the lofty snow-clad mountains, here known as the Sierra Guadarrama and the Somosierra, separating Old from New Castile. The province is watered by numerous affluents of the Douro, which take their rise in these mountains, and flow in a north-westerly direction. The largest of them are the Riaza, Duraton, Cega, and Eresma. The average height of the plain in this province is not less than 3000 feet above the sea. Its appearance is dull and monotonous in the extreme, being entirely destitute of meadows and trees. It is, however, a good agricultural country, in which wheat, rye, barley, peas, hemp, flax, vines, &c., are raised. On the lower slopes of the mountains there are considerable pine-forests; and on the mountain-pastures, sheep, cattle, mules, pigs, &c., are reared. Mines have been wrought in some parts of Segovia, but not with much success, or to any large extent. There are also quarries of granite, limestone, and chalk. The majority of the inhabitants are employed in agricultural or pastoral pursuits. Weaving is carried on to some extent, as also is paper-making, tanning, and the manufacture of earthenware. Pop. (1857) 162,082.

Segovia, the capital of the above province, stands on a long rocky knoll, at the confluence of the Eresma with the turbulent rivulet Clamores, 45 miles N.W. of Madrid, 3300 feet above the level of the sea. It is surrounded by dilapidated old walls, with round towers; and has long, narrow, irregular streets, lined with quaint old-fashioned houses. Above the meeting of the waters rises the ancient Alcazar, or castle, on the summit of the cliff. It contains some fine halls, and is now used as a school of artillery. The cathedral is one of the finest in Spain, and the last of those in the pure Gothic style. It was begun in 1525, the former one having been almost destroyed in a popular rising in favour of the Reformation. The tower, which is 330 feet high, commands a magnificent view. The most interesting erection about Segovia, however, is the ancient aqueduct, supposed to have been built in the time of Trajan. It conveys water to the town from the Sierra Fonfria, as that of the river is difficult of access and not very wholesome. That part which is raised on arches is 847 yards in length, consisting of two tiers of arches, built of granite blocks, without any cement. The height at the centre where it is highest is 102 feet. This great work is in very good preservation; and for simplicity, grandeur, and utility, is well worthy of admiration. Besides the edifices already mentioned, Segovia possesses numerous churches, a mint, where only copper is now coined, various schools, a picture gallery, theatre, several hospitals, &c. It was formerly a very prosperous town, on account of its manufacture of woollen cloth; but it has never recovered from the blow inflicted by the French, who took the place in 1808; and though no resistance was offered, sacked it. They continued to occupy the town till 1814. Some insignificant manufactures are still carried on; leather, paper, and earthenware, being the chief articles. Pop. 13,100.

SEGUIDILLA, the Spanish name of a quick and animated melody in $\frac{3}{4}$ time, much used in Spain in singing and in dancing.

SEIFHENNERSDORF, a town of Saxony, in the circle of Bautzen, near the Bohemian frontier, 9 miles N.W. of Zittau. It has a fine church, several schools, extensive manufactories of linen and nankin, bleach-fields, &c. Pop. 5868.

SEIGNIOR, or Signior, is, in its general signification, the same with lord, but is particularly used for the lord of the fee or of a manor, as seigneur among the feudists is he who grants a fee or benefit out of the land to another. Having granted away the use and profit of the land, the seignior still retains within himself the property or dominion.

SEIGNIORAGE is a royalty or prerogative of the king, by which he claims an allowance of gold and silver brought in the mass to be exchanged for coin. See Coinage.

SEIGNIORY is borrowed from the French *seigneurie*, which means *dominatus, imperium, principatus*, and signifies with us a manor or lordship, *seigniory de sokemans*. *Seigniory in gross* seems to be the title of him who is not lord by means of any manor, but immediately in his own person; as *tenure in capite*, by which one holds of the king, as of his crown, is *seigniory in gross*.

SEINE (anc. *Sequana*), a river of France, rises in the department of Cote d'Or, in the heights of Langres, which separate it from the valley of the Saône. The general direction of its course throughout is towards the N.W.; but it has many curves and windings. It traverses the departments of Aube, Seine-et-Marne, Seine-et-Oise, Eure,

Seine.

and Seine-Inférieure; and falls into the English Channel by a wide estuary, south of Havre. Its whole length is 470 miles, though the distance in a straight line from its source to its mouth is only 270. The river is navigable for large vessels up to Rouen, and for boats as far as Méry, below Troyes, 380 miles from its mouth; but by means of a canal, vessels may ascend as far as Troyes. There are falls at Nogent-sur-Seine; but these are surmounted by locks. The waters of the Seine are connected by means of canals with those of the Rhone, the Loire, and the Scheldt. The chief affluents of the rivers are, from the right, the Aube, the Marne, with its tributary the Ourcq, the Oise, and the Epte; and from the left the Yonne, Loing, Eure, and Rille. It flows through a rich and beautiful region of hill and dale, studded with many splendid mansions, picturesque villages, and busy towns. The principal of the latter that stand on its margin are Chatillon, Bar-sur-Seine, Troyes, Nogent-sur-Seine, Melun, Paris, Mantes, Rouen, and Havre. None of the rivers of France are more abundantly stocked with fish. The elevation of the Seine at its source is 1426 feet above the sea, and the greater part of its fall takes place in the upper part of its course; for at Troyes it is only 330 feet above the sea. Its width at Paris is from 300 to 500 feet, and at its mouth about 7 miles. Owing to the comparatively small incline of its course, the Seine flows with a smooth gentle current, and is not subject to violent inundations. Its estuary is somewhat encumbered with shifting sand-banks; and like that of some other rivers, is exposed every tide to a huge perpendicular wave from the sea, called the barra or bore. In a commercial point of view the Seine is most important, as it greatly facilitates the supply of the capital both with articles of rural produce from the country in the upper part of its course, and with foreign merchandise from its mouth.

SEINE, the metropolitan department of France, and in consequence the most populous, though the smallest of the whole, lying between N. Lat. 48. 43., and 48. 58.; E. Long. 2. 10., and 2. 35.; bounded on all sides by that of Seine-et-Oise. It is compact, and nearly circular in form; 18 miles in length, 16 across at the widest part; and 183 square miles in extent. Of this area, 103 square miles are included within the fortifications of Paris. The surface is, in general, level or undulating; the highest elevations being those of Montmartre and Chamont, the former of which is 346 feet above the sea. The rivers Seine and Marne, the latter of which joins the former within the department, flow, with many bends and sinuosities, through the country. In geological structure the department belongs to the tertiary formation, and contains limestone, gypsum, and marl. Good building-stone and porcelain-clay are also obtained. There are some mineral-springs within the limits of the department. The soil is throughout fertile; and its natural productiveness is increased by a plentiful supply of rich manure from the capital. It is carefully cultivated, and only a few acres out of nearly 120,000 are altogether waste. There are in the department 73,227 acres of arable land, 3857 of meadows, 6960 of vineyards, 3385 of forests, and 625 of heaths. Near Paris fruits and vegetables are the principal crops raised; wine is made, but not of a very good quality; and in the outskirts of the department all the ordinary kinds of corn are grown. There are also extensive meadows, on which sheep and cows are reared. The sheep are, in general, of a common but improved breed, and there are many flocks of merinos. The department is calculated to contain 38,000 horses, 18,000 head of horned cattle, 30,000 sheep, 4000 pigs, &c. Portions of the department are occupied with pleasure-grounds belonging to the capital; such as the park of Vincennes to the east, and the Bois de Boulogne to the west of the city. The manufactures and commerce of the department are most extensive and varied. They are all concentrated in the capital, and are noticed in the article PARIS. Internal communication is facilitated by the two navigable rivers, four canals, and numerous roads and railways, which diverge from the metropolis in all directions. Many of the roads are lined with double rows of lofty trees, and thus form magnificent approaches to the city. Seine forms the diocese of the archbishop of Paris; it is included in the jurisdiction of the Imperial Court at Paris, and contains a civil court, formed of eight chambers, and a tribunal of commerce. It is in the first military division. The arrondissements are as follows:—

	Cantons.	Communes.	Pop. (1856.)
Paris	...	1	1,174,346
Saint-Denis	4	37	356,034
Sceaux	4	43	197,039
Total	8	81	1,727,419

Seine-et-Marne.

SEINE-ET-MARNE, a department of France, lying between N. Lat. 48. 8. and 49. 8., E. Long. 2. 24. and 3. 32.; bounded on the N. by the departments of Oise and Aisne, E. by those of Marne and Aube, S.E. by that of Yonne, S. by that of Loiret, and W. by that of Seine-et-Oise. Length from N.N.E. to S.S.W., about 74 miles, greatest breadth 45; area, 2273 square miles. The surface is broken by no mountains or even hills, but consists of a wide-spread undulating country, with many extensive plains. It is watered by two important rivers, the Seine and its affluent the Marne; the former traversing the south, and the latter the north of the department, both in the same direction, from east to west. There are three other navigable rivers, the Ourcq, the Grand Morin, and the Yonne; the first two falling into the Marne, and the latter into the Seine, all having parts of their courses in the department. Of less size and importance are the Loing, Petit Morin, and Yêres, the last having its source in this department. In the centre and east of the country are many artificial ponds for the breeding of salmon. The geological structure of the south-eastern parts of Seine-et-Marne is cretaceous, in the other portions the tertiary strata prevail. Many valuable minerals are obtained in different places. Such are the sandstone of Fontainebleau, the fine millstones of Ferté-sous-Jouarre, the building-stone of Chateau London, the potters' clay of Montereau, &c. The country, however, is chiefly agricultural; and in this respect it is inferior to none of the other departments of France. It possesses a rich soil, and is diligently cultivated. About two-thirds of the whole area, or 917,500 acres, are under the plough; 82,000 acres are occupied by meadows, 47,500 by vineyards, and 200,000 by forests. Of corn, the principal kinds raised here are wheat and barley; rye and oats not to so great an extent. Potatoes, pulse, vegetables, hemp and flax, are also raised. The wine produced is abundant in quantity, but not very excellent in quality. A large extent of ground is occupied by gardens and orchards. Cider is extensively made. The forests abound in game, and supply excellent timber, especially oak. On the meadows and uninclosed pastures, large numbers of live stock are fed. The number of horses in Seine-et-Marne is estimated at 36,000; of horned cattle, 85,000; of sheep, 75,000; of pigs, 23,000; of goats, 2000; of asses and mules, 3600. The sheep, which are mostly of the Merino breed, furnish an important part of the wealth of the country. There are also a large number of cows; and this department contributes to supply Paris with milk and cheese. The manufactures are various, but of no great importance. Among them are the pottery of Montereau, the paper of Marais, calico, leather, hardware, and other articles. Many of the people are employed in the quarries. An active trade is carried on in this department in the agricultural produce of the country, which is sent to Paris; also in cheese, timber, wool, manufactured goods, &c. Besides its

Seine-et-Oise.

five navigable rivers, the department is traversed by three railways, leading from Paris to Strasburg, Mulhouse, and Lyons, respectively, as well as by numerous roads. Seine-et-Marne forms the diocese of Meaux, and is under the jurisdiction of the Imperial Court at Paris. It contains 5 primary courts and 3 tribunals of commerce; 4 colleges, and 577 elementary schools. It is included in the first military division. The capital is Melun, and the five arrondissements are as follows:—

	Cantons.	Communes.	Pop. (1856.)
Melun	6	106	62,164
Fontainebleau	7	104	78,167
Meaux	7	161	91,515
Coulommiers	4	80	53,876
Provins	5	106	55,660
Total	29	557	341,382

Seine-et-Oise, a department of France, lying between N. Lat. 48. 18. and 49. 10., E. Long. 1. 29. and 2. 24.; bounded on the N. by the department of Oise, E. by that of Seine-et-Marne, S. by that of Loire, S.W. by that of Eure-et-Loire, and N.W. by that of Eure, entirely surrounding that of Seine. Length from N.W. to S.E. 70 miles; greatest breadth, 52; area, 2164 square miles. It consists of a beautiful expanse of country, rising in some places into hills of moderate elevation, with gentle slopes and level plains in other parts; the whole being richly cultivated and studded with stately forests, magnificent parks, noble castles, and quiet hamlets, with the placid stream of the Seine meandering through the land, and uniting with that of the Oise from the N.E. The other rivers are of smaller size, such as the Yêres and Epte, Essonne, and Orge, falling into the Seine. In its geological structure the greater part of the department belongs to the tertiary basin, in which Paris stands; but a narrow strip in the west is composed of chalky formations. Sandstone, paving-stone, millstones, chalk, plaster, potter's clay, and other minerals, are found in the department. There are sulphuric springs at Enghien, and at some other places within the limits of Seine-et-Oise. The climate is salubrious and temperate. The soil, not remarkably fertile by nature, has been rendered productive by careful cultivation. Agriculture is the principal source of wealth. Corn and wine are produced in superabundance. Potatoes, pulse, beet-root, and rape are also raised; and there are many orchards and forests which furnish large quantities of fruit and timber. The department contains 917,500 acres of arable land, 50,000 of meadows, 42,500 of vineyards, 195,000 of forests, and 27,500 of heaths and waste land. On the meadows are reared large numbers of live stock, especially sheep. The sheep-folds of Rambouillet, in this department, are celebrated. It is calculated that there are in Seine-et-Oise 70,000 cows, 520,000 sheep, 30,000 pigs, 55,000 horses 10,000 asses, &c. Poultry and fish abound in the department, but game has become exceedingly scarce. Besides agricultural and pastoral employments, many of the inhabitants are engaged in manufactures of various kinds. The celebrated porcelain of Sèvres is one of the most important of the articles manufactured; and among the others are cotton and linen cloth, hosiery, paper, fire-arms, gunpowder, &c. In these articles, as well as in corn, wool, and timber, an active trade is carried on. Besides three navigable rivers, the Seine, Marne, and Oise, there are in the department a canal and numerous roads; while all the railways that diverge from Paris traverse it for a longer or a shorter distance. Seine-et-Oise forms the see of Versailles, and is subject in legal matters to the Court of Appeal at Paris. It has a lyceum, two colleges, a normal seminary, and 1100 elementary schools. The capital is Versailles, which has a population of about 36,000, and there are six arrondissements, as follows:—

	Cantons.	Communes.	Pop. (1856.)
Versailles	10	114	162,449
Mantes	5	126	57,328
Rambouillet	6	119	66,840
Corbeil	4	94	61,557
Pontoise	7	165	95,256
Etampes	4	60	40,749

Seine-Inférieure.

Seine-Inférieure, a department of France, lying between N. Lat. 49. 15. and 50. 4., E. Long. 0. 2. and 1. 49.; bounded on the N. and W. by the English Channel, S. by the department of Eure, and E. by those of Oise and Somme. Length from E. to W. 76 miles; greatest breadth, 45; area, 2326 square miles. A low branch of the Ardennes traverses the country from east to west, terminating on the sea at Cape La Hève, which is the most westerly point of the department, and the only considerable headland on its coast. This chain of hills separates the waters of the Seine from those that flow into the Channel; on either side of it are extensive plains, furrowed by valleys of no great depth, which are bordered with low sloping hills. The coast is almost entirely formed of chalk cliffs, interrupted only where the rivers fall into the sea. These cliffs attain their highest elevation, 700 feet above the sea, at Fécamp, nearly opposite Beachy Head, in Sussex. The principal river in the department is the Seine, which pursues its tortuous course along the southern boundary, and receives many small affluents from the north. The largest of these are the Epte and the Andelle, which have their sources, and the upper part of their streams, in Seine-Inférieure. Of the rivers that flow directly into the Channel, the principal are the Bresle, the Yères, and the Arques, with its affluents, the Eaulne and the Béthune. The country belongs entirely to the cretaceous formation. Many valuable minerals are obtained, such as marble, building-stone, marl, chalk, potter's-clay, sand for glass-works, peat, &c. There are mineral-springs in several places, but those of Forges alone are frequented. The climate is moist, and in general colder than that of the opposite coast of England. Although the department contains many very rich tracts of ground, yet as there are large portions of a very different character, it is on the whole not remarkable for fertility. But agriculture is in a flourishing state; improved modes of cultivation and manuring are employed; and the farms are in general distinguished by the neatness of their homesteads and gardens. Along the sea-shore there are many swampy and sandy tracts; among the hills much ground adapted only for pasture; and in the south of the department many large forests. The extent of arable land is 945,000 acres; of meadows, 70,000 acres; of forest, 170,000 acres; and of heaths, 45,000 acres. Wheat is the principal kind of corn raised. Pulse, turnips, rape, potatoes, hemp, and flax, are also among the crops grown. Much of the ground is laid out in gardens and orchards, which yield various kinds of fruit. The horses of the country are good for draught; the cattle and sheep are of inferior breeds. It is calculated that the department contains 90,000 horses, 150,000 head of cattle, 550,000 sheep, and 60,000 pigs. The Seine abounds in salmon, sturgeon, soles, and other fish; and there are also, along the coast, productive fisheries, which supply the Parisian market with herring, mackerel, and oysters. The department is celebrated for its manufacturing industry, which is actively carried on in every part, and especially in the large towns. There are a great number of bleach-fields, which give to cloth a superior whiteness above those of other parts of the kingdom. All sorts of cotton and woollen manufactures are also carried on, the former especially at Rouen; leather, silk, glass, pottery, bricks, sugar, and chemical substances are among the other goods manufactured. There are twelve ports in the department, the chief of which are Dieppe,

Fécamp, Havre, Harfleur, and Rouen. Through these a considerable trade is carried on with England and other countries; and by means of the Seine commercial intercourse is kept up with Paris. The department is traversed by two railways, from Paris to Havre, and from Rouen to Dieppe. Seine-Inférieure forms the diocese of Rouen, and contains several law-courts, subordinate to the Court of Appeal at Rouen. There are a lyceum, 5 colleges, a normal seminary, 4 upper and 1128 elementary schools. The chief town is Rouen, and the department is subdivided into 5 arrondissements, as follows:—

	Cantons.	Communes.	Pop. (1856.)
Rouen	15	155	265,602
Dieppe	8	168	112,769
Les Havre	9	122	175,014
Neuchatel	8	145	81,339
Yvetot	10	170	134,726
Total	50	760	769,450

SEISIN. See INFEFTMENT.

SEISTAN, formerly called *Segestan*, and sometimes *Nimroz*, a khanat or principality of Asia, forming the southwest portion of Afghanistan, bounded on the north by Herat, east by Kandahar, south by the Great Desert, which separates Afghanistan from Beloochistan, and west by Persia. It lies between N. Lat. 30. 30. and 32. 0., E. Long. 61. 0. and 62. 30., and is nearly oval in form, about 100 miles in length from N. to S., and 60 in breadth, with an area of about 5000 square miles. Though this region is raised to a height of probably not less than 2500 feet above the sea, it is, in comparison with the surrounding country, very much depressed. From the southern foot of the great Caucasian Mountains, which traverse Afghanistan from E. to W., a vast expanse of desolate ground stretches to the S.W., gradually sloping downwards, till it is met on the west by a chain of hills extending southwards, and on the south by the elevated desert of Beloochistan. In the lowest part of this vast slope lies Seistan. The whole country is an extensive plain, except one small hill near the eastern shore of the Great Lake, or Hamoon. This is merely a sheet of shallow water, or swamp, into which the rivers flow from the surrounding countries, for none of the streams that enter Seistan can flow out from it again. They consequently stagnate in the more depressed places, and form shallow lakes, which are constantly changing their form and size. The largest of these is the Great Hamoon, about 70 miles long, and from 15 to 20 wide. The principal rivers that flow into Seistan are the Helmund, the Khash Rood, and the Ibrahim Joi, from the east; the Furrah Rood and Adruscund from the north; and the Bundau from the west. All these, even the largest, are rather mountain-torrents than perennial rivers, rushing down at one time with a full volume of muddy water, and at another with merely a small stream in the bottom of the channel, which, in the case of the smaller rivers, is left dry altogether. Most of the lakes and morasses are imbued with salt, so that the water is frequently not drinkable. The soil in some parts is rich and fertile, and along the banks of the Helmund it is well cultivated; but the climate is excessively hot, and the atmosphere unhealthy. Wheat, rice, and other grains, as well as cotton and tobacco, are grown. There are no forests here, but dense jungle of tamarisks cover, in many parts, the face of the country. Beasts of prey, such as leopards, wolves, jackals, hyænas, &c., abound here; there are also many wild-asses, wild-boars, deers, porcupines, hedgehogs, &c. Domestic animals do not thrive well here; horses cannot be kept, and cows are subject to a great mortality. The majority of the inhabitants are of Persian origin, but there are also many Afghans and Beelooches, and a few Hindus. They live in felt tents, and are mostly employed in hunting and fishing. Their language is a broken Persian, and their religion Mohammedanism. They are governed by a khan who resides at Dovshak, but who has little power on account of the numerous petty chieftains in the country. Seistan was once a fertile and flourishing country, full of large and magnificent cities, whose ruins still lie strewed for miles over the plain. The rivers were embanked, and the soil enriched by a careful system of irrigation. All this prosperity was destroyed by the conquest of the country in 1383, by Tamerlane, who exterminated the inhabitants, and laid the towns in ruins. The present population is from 50,000 to 60,000.

SEJANT. See HERALDRY.

SEJANUS, LUCIUS ÆLIUS, an infamous tool of the Emperor Tiberius, was a native of Vulsinii, in Etruria, and was son of Seius Strabo, a Roman knight who flourished during the reign of Augustus and the beginning of that of Tiberius. After spending a very immoral youth, Sejanus at length gained the favour of the reigning sovereign, Tiberius. Once the wily youth had the emperor in his grasp, nothing could part them but the death of either, as it subsequently proved. Possessed of a body capable of enduring the most unheard of fatigues, endowed with a mind fit for the highest species of subtlety and cunning, of manners the most polite and insinuating towards his equals, the most cringing towards his superiors, and the most haughty and imperious to those beneath him, the weak emperor, in opening his bosom to Sejanus, disclosed himself unwarily to a most subtle intriguer. On the death of Augustus, in A.D. 14, Sejanus was sent by Tiberius, together with his son Drusus, to quell the insurgents in Pannonia. On the father of Sejanus being sent to Egypt, the son was chosen sole commander of the prætorian cohorts. He urged upon Tiberius the propriety of concentrating these bands all in one place, and he instructed him not to divide their powers of effective action by scattering them throughout the city. The emperor complied. The object of Sejanus was to popularize himself with the soldiery, and he succeeded to admiration. He dealt out honours to the prætorian guard with lavish hand, which came back to him in statues and busts in the public places of Rome. It was evident Sejanus aspired to the purple. There was, however, more than one obstacle in his path, which he resolved silently to remove. Drusus, the son of Tiberius, and the children of Germanicus, all stood in his way. He seduced the wife of Drusus, and by promising her immediate marriage, and a participation in the imperial power to which he aspired, induced her to poison her husband. Sejanus now divorced his wife Apicata, and solicited the emperor to permit him to wed the wife of the murdered Drusus. The emperor couched his answer in ambiguous language. Sejanus now required to act with caution. After various manœuvring, he induced the emperor to shut himself up in the island of Capræa, where he had full scope for his machinations. The death of Livia, the mother of Tiberius, was soon followed by the banishment of Agrippina, the wife of Germanicus, and her two sons, Nero and Drusus. The path was now clear before Sejanus; yet Tiberius, who possessed more than his share of cunning, began to suspect him. The emperor had duplicity sufficient to conceal his suspicions. He made the tyrant joint consul with himself, and elevated him and his son to a pontificate. Sejanus felt the ground giving way under him, but what could he do to prevent it? Sertorius Macro was sent to Rome to assume the command of the prætorian cohorts, with a letter from Tiberius which he was to read to the senate. The emperor could never express himself clearly when he wished to say anything dangerous to the imperial power. The senate and the populace caught the drift of the royal epistle, however, which was plainly to have done with Sejanus. No word of consolation was spoken for the great criminal. He was conducted to prison, amid the hootings and yellings of the multitude,

who tore down his statues and busts as he passed them by. Next day his body was dragged through the streets of Rome, and what remained of it was flung into the Tiber. The chief authorities for the history of Sejanus are Tacitus, Suetonius, and Dion Cassius.

SELBY, a market-town of England, in the West Riding of Yorkshire, on a flat spot on the right bank of the Ouse, 14 miles S. by E. of York, and 175 N.N.W. of London. It is well though irregularly built, consisting of four principal streets, meeting in a central market-place, in which stands an old Gothic cross. The most conspicuous edifice is the noble old parish church, which originally formed part of a Benedictine abbey, founded by William the Conqueror in 1068. It is cruciform in plan, partly in the Norman and partly in the early English styles; its dimensions are 267 feet by 100. In it are some fine specimens of stained glass and carved stone-work. The other places of worship in the town belong to Wesleyan and Primitive Methodists, Independents, Baptists, Quakers, Roman Catholics, and Unitarians. Among the public buildings of Selby there are also a town-hall, and another hall for public meetings, erected in 1841. There are various schools and libraries, a mechanics' institution, and a news-room. The manufacturing establishments include boat-building yards, iron and brass foundries, breweries, tanneries, sailcloth and rope manufactories. The river is navigable up to Selby for vessels of 200 tons, and is crossed here by a moveable wooden bridge. A considerable trade is carried on in corn and cattle, as well as in the produce of the manufactures. Besides weekly markets, several annual fairs are held here. Pop. (1851) of the town, 5109; of the parish, 5340.

SELDEN, JOHN, one of the most learned men of his time, as well as a distinguished statesman and lawyer, was born at Salvington, in Sussex, on the 16th December 1584. His father was John Selden, a minstrel, and his mother, whose heart the minstrel is said to have won by his proficiency in music, was Margaret Baker, a descendant of a knightly family of that name in Kent. Their son John received his early education at the free grammar school of Chichester, where he progressed so rapidly in his studies, that he was removed to Hart Hall, Oxford, at the early age of fourteen. After remaining there for four years, he entered himself at Clifford's Inn for the study of law, and in 1604 he removed to the Inner Temple. "After he had continued there," says Wood, "a sedulous student for some time, he did, by the help of a strong body and a vast memory, not only run through the whole body of the law, but became a prodigy in most parts of learning, especially in those which were not common, or little frequented or regarded by the generality of students of his time. So that in a few years his name was wonderfully advanced, not only at home, but in foreign countries, and was usually styled the great dictator of learning of the English nation." His reputation for learning, particularly on all subjects connected with law, must speedily have gained him a lucrative practice, though he was more employed as a conveyancer and chamber counsel than as a pleader. Indeed, judging from what of his speeches remain, eloquence cannot be said to have been one of his distinguishing qualifications. His earliest work, the *Analecton Anglo-Britannicon*, a chronological digest of records relating to the history of England previous to the Norman invasion, was finished in 1607, but was not published till eight years afterwards. In 1610 appeared his *England's Epinomis*, and *Jani Anglorum facies altera*, both illustrative of the state and progress of English law; and the same year he published an essay on *The Duel* or *Single Combat*. In 1614 appeared his largest English, and in the opinion of some his best, book, on *Titles of Honour*, a work which is still regarded as an authority upon that subject. In 1617 he published the first edition of his celebrated work, *De Diis Syris*, and the following year his *History of Tithes*. In the latter of these works, while maintaining the legal, he denied the divine right of the clergy to receive tithes; and in consequence was summoned before the High Commission Court, when he had to make a public acknowledgment of his sorrow for having published his opinions, though he did not in any way recant them.

In 1621, Selden, though not then a member of the House, was sent for by the Commons to give his opinion on the questions in dispute between them and the Crown. On that occasion he advised them so strongly to maintain their rights and privileges, that he was committed to prison; but through the influence of the bishop of Winchester, he was liberated after an incarceration of five weeks. In 1624 he sat in Parliament as one of the representatives of the borough of Lancaster, but took no prominent part in the business of that session. The same year he was chosen reader of Lyons Inn, but refused to accept the office, which so offended the benchers that they ordered him to be fined, and to be for ever disabled from being called to the bench. This order, however, was subsequently rescinded, and Selden was called to the bench in 1632. In the first parliament of Charles I., which met in 1625, Selden sat as one of the representatives of Great Bedwin, and declared himself so warmly against the Duke of Buckingham, that when, in the following parliament, his Grace was impeached by the House of Commons, he was one of the members appointed to prepare the articles and to manage the prosecution. In the parliament which met in March 1628, Selden again represented the town of Lancaster, and took a very prominent part in the proceedings. He rendered very efficient aid in the preparation of the celebrated Petition of Rights, and was one of the speakers appointed to confer with the Upper House in order to obtain its concurrence in an address to the king. The result was, that the measure, having the support of both Houses, at length received the reluctant assent of the king. Selden was also one of those that drew up a remonstrance to the king for the removal of Buckingham, and demanded that judgment be given against him upon the impeachment of the last parliament; and also a remonstrance declaring that the impost of tonnage and poundage was no prerogative of the crown. In all these matters Selden's vast learning was of the utmost importance. His knowledge of the laws and constitution of the country furnished him with numerous authorities, and enabled him to support his arguments with an unanswerable mass of facts and precedents. It was in this that he was chiefly distinguished as a debater.

During the recess he applied himself to literary pursuits, and gave to the world his *Marmora Arundeliana*, an account of the Arundelian Marbles, which had lately been brought to England. Parliament again met in January 1629, and Selden appeared more active than ever in the popular cause. The violent opposition of this parliament to the measures of the court speedily brought about its dissolution, and Selden with several others were committed to the Tower. At first their treatment was extremely harsh and rigorous, being denied even the use of books or writing materials. At length, after a confinement of eight months, they were brought up before the King's Bench, and offered their liberty upon granting security for their good behaviour. This, however, was refused; and, though the strictness of their confinement was more and more relaxed, till it became little more than a name, it was not till May 1631 that Selden, through the influence of the Earls of Arundel and Pembroke, was liberated on bail, and not till the beginning of 1634 that he received a free discharge. In 1646, parliament voted L.5000 to be paid to each of these gentlemen, or their heirs, for the losses they had sustained on this occasion. Among the fruits of this period were his two learned works, *De Successionibus in Bona*

Defuncti ad Leges Hebræorum, and *De Successione in Pontificatum Hebræorum.*

In 1635 was published his *Mare Clausum*, a work written a good many years before in answer to Grotius's *Mare Liberum*, and now published at the request of the king, in consequence of a dispute with the Dutch regarding their fisheries on our shores. It was dedicated to his majesty, and this has been regarded by many as indicating a change in Selden's views regarding the court party. Be this as it may, we do not find that he was so frequently or prominently opposed to the court party as formerly. The next four years of Selden's life yield us nothing of interest; but at the end of that period he published his *De Jure Naturali et Gentium juxta Disciplinam Hebræorum.* It is not a little remarkable that Selden does not appear to have taken any part in the great Ship-money case of 1638, although his services would have been of the utmost value on behalf of Hampden. It may be that he declined to interfere, or perhaps the Hampden party saw reason to suspect him of an inclination towards the court party.

In 1640 he was unanimously chosen to represent the University of Oxford in the Long Parliament, and we now find him not only less violently opposed to the Crown party, but very frequently supporting their measures. He gave his opinion with the king as to the right of the bishops to a seat in parliament; and though he was one of the members named by the House to prepare the accusations against the Earl of Strafford, he was not one of those appointed to conduct the prosecution, and voted against the majority who condemned the earl. He also opposed the resolutions of the House which led to the exclusion of the bishops from parliament. The Lord Keeper Littleton having displeased the king, Charles wrote to Lord Falkland requiring that the great seal be taken from the present keeper, and given either to Banks or Selden. That this offer was made by the king from a belief that Selden was in his interest, may be readily supposed, seeing that afterwards, when Selden opposed in the House the king's Commission of Array, his majesty was much troubled, and desired Lord Falkland to write a friendly letter to Selden on the subject. Selden acknowledged that he had spoken all the more strongly against the commission, in order that he might be able to speak the more freely against the ordinance of the parliament for the militia, to which he was equally opposed, and which was to be brought up for discussion on a subsequent occasion. This he also did his utmost to overthrow, but unsuccessfully. In 1643 he was appointed one of the lay members to sit in the Assembly of Divines at Westminster, and the same year he was appointed by the House of Commons keeper of the records in the Tower. In 1644 he subscribed the Solemn League and Covenant, and the following year he was one of the twelve commoners chosen Commissioners to the Admiralty. The same year he was chosen Master of Trinity Hall, Cambridge, an honour which he declined; and in 1647 he was appointed one of the parliamentary visitors of Oxford University.

When Selden found that there was no possibility of a reconciliation being effected between the king and the parliament, he seems to have withdrawn himself from the arena of political strife. His name does not appear among those members who were imprisoned or expelled by the army, nor yet among those who continued to assume the office of legislators. He took no part in the arraignment of the king, and it does not even appear what his opinion was on that transaction. Cromwell seemed desirous to secure his services, and is said to have applied to him, personally and through mutual friends, to answer the *Eikon Basilike*, but he declined. Whatever opinion may be formed of Selden's conduct latterly, it is no small argument in favour of his consistency and uprightness, that he retained the confidence and good-will of both parties at a time when party feeling ran so high. The true explanation seems to be, that, foreseeing the calamities of a civil war, to which the violent proceedings of the popular party were evidently leading, he did what he could to check them. He died, on 30th November 1654, at White Friars, the house of the dowager Duchess of Kent, with whom he lived as legal adviser, and to whom he is said by some to have been married. "Mr Selden," says Lord Clarendon, "was a person whom no character can flatter, or transmit in any expressions equal to his virtue. He was of so stupendous learning in all kinds, and in all languages (as may appear in his excellent and transcendent writings), that a man would have thought he had been entirely conversant amongst books, and had never spent an hour but in reading and writing; yet his humanity, courtesy, and affability was such, that he would have been thought to have been bred in the best courts, but that his good nature, charity, and delight in doing good, and in communicating all he knew, exceeded that breeding. His style in all his writings seems harsh, and sometimes obscure, which is not wholly to be imputed to the abstruse subjects of which he commonly treated, out of the paths trod by other men, but to a little undervaluing the beauty of a style, and too much propensity to the language of antiquity; but in his conversation he was the most clear discourser, and had the best faculty of making hard things easy, and presenting them to the understanding, of any man that hath been known." Among his later works may be mentioned *De Anno Civili et Calendaris Reipublicæ Judaicæ; Uxor Hebraica seu de Nuptiis et Divorciis; De Synedriis et prefecturis Juridicis veterum Hebræorum; De Nummis.* A complete edition of his works, with a Memoir of the Author, by Dr David Wilkins, appeared in 6 vols. folio, 1726. Selden's name is best known in the present day by his *Table-Talk*, a work published thirty-five years after his death by Richard Milward, who had acted as his amanuensis for twenty years. It is a collection of his remarks and opinions on various subjects, especially relating to religion and politics.

SELEUCIA, or SELEUCEIA (Σελεύκεια), several ancient cities founded by Seleucus Nicator, king of Syria, and called after his name. The most important are the following:—

SELEUCIA PIERIA, the seaport of Antioch, on the north side of the Bay of Antioch, at the foot of a mountain anciently called Coryphaeum, now Jebel Musa, about 8 miles N. by W. of the mouth of the Orontes. It was strongly fortified with a double line of defences, connected with a castellated fort on the summit of the hill. The harbour was well suited for the galleys of the ancients, and of its substantial piers considerable portions still remain. Besides the outer port, formed by two piers, there was an inner basin, to which an entrance was cut through the solid rock, and defended by a tower on each side. For supplying water to the harbour a great work was constructed, consisting partly of tunnels and partly of deep cuttings, for a distance of 1088 yards. Of all these structures, as well as of several temples, an amphitheatre, and many tombs in the rocks, considerable remains are yet to be seen, confirming the accuracy of the description that Polybius gives of the city. Seleucia was a place of much importance in the wars between the Syrian and Egyptian monarchs. It was taken by Ptolemy Euergetes during his invasion of Syria, and retained by the Egyptians until the time of Antiochus the Great. This monarch led an army against the city, and by taking the suburb and arsenal, forced it to surrender, about 220 B.C. Seleucia afterwards passed into the hands of the Romans, and received from Pompey the dignity of a free city. It is noted in Scripture history as the place where Paul set sail on his first missionary journey (Acts xiii. 4).

SELEUCIA TRACHEOTIS, an important town of Cilicia, in

a fertile plain on the left bank of the Calycadmus, about 68 miles S.W. of Tarsus. It was well built, much superior in style to the other towns of the country, and attracted many to it on account of the beauty of its situation, as well as an oracle of Apollo which it possessed, and an annual festival which was held here. No historical event of any importance is connected with the name of Seleucia Tracheotis. Extensive remains of the ancient city still exist at a place called Selefkieh. Among these may be traced a theatre, temple, and other large buildings.

SELEUCIA-ON-THE-TIGRIS, so called from its position, in order to distinguish it from the other towns of that name, stood at the point where an artificial canal connected the waters of the Euphrates and Tigris, 40 miles N. of Babylon. It was a large and important city, containing, it is said, in the time of its prosperity, a population of 600,000 souls; and it was second in commercial importance only to Alexandria. Having been the capital of the Macedonian possessions in the East, Seleucia still retained, after the fall of that empire, an independent position, and a thoroughly Greek character. It was governed by a senate of 300, was strongly fortified, and thus able to defy the power of the Parthians, whose empire reached almost to the gates. The oriental city of Ctesiphon rose on the other side of the Tigris, only three miles off, and finally supplanted Seleucia in the power and splendour which it had inherited from the old Babylon. It was the Romans, however, who took and sacked Seleucia, notwithstanding its hostility to their enemies, 165 A.D. From this blow the city never recovered; and the place relapsed into a marshy desert.

SELEUCIDÆ, or the Syro-Macedonian era, is a computation of time, commencing from the establishment of the Seleucidæ (by Seleucus Nicator), a race of Greek kings, who reigned as successors of Alexander the Great in Syria, as the Ptolemies did in Egypt. This era we find expressed in the books of the Maccabees, and on a great number of Greek medals struck by the cities of Syria. The Jews call it the era of contracts, and the Arabs the era of the two horns. According to the best accounts, the first year of this era falls in 311 B.C., being twelve years after Alexander's death.

SELEUCUS I. and his successors. See SYRIA.

SELIM. See TURKEY.

SELIMNO, SELIMNIA, or ISLEMJE, a town of European Turkey, Rumelia, in the eyalet, and 70 miles N. by W. of Adrianople, at the south foot of the Balkan Hills. It is enclosed by walls, and contains three mosques. Here are extensive plantations of roses, and manufactures of the essence of roses, of cloth, and of highly-prized fire-arms and gun-locks. Large fairs are held here; and it is one of the most important places of trade in Turkey. The inhabitants are almost all Bulgarians. Pop. 20,000.

SELINUS, the most westerly, as well as one of the most important, of the Greek colonies in Sicily, on the south coast of that island, at the mouth of a small river, 4 miles W. of the Hypsas. The original settlers came partly from Megara Hyblaea, on the east coast of Sicily, and partly from Megara in Greece, the parent city of that colony. The date of the settlement is not exactly known, but was probably about 628 B.C. It derived its name (from σελινὸς, wild parsley) from the quantities of that herb which grew in the vicinity, and adopted a sprig of it as the symbol of the city. Selinus rapidly rose to a high degree of power and prosperity; but was involved in frequent contests with the aborigines and the Carthaginians. The city of Segesta, too, was a formidable rival, and frequently an enemy. Selinus was in alliance with Carthage when Hamilcar undertook his expedition against Sicily in 480 B.C., but rendered no effectual aid to that general. But at the time of the Athenian expedition against Syracuse, Silenus had enjoyed half a century of peace and prosperity, and acquired great military resources and large stores of wealth. In the disputes between Selinus and Segesta, the former called in the aid of Syracuse, and the latter that of Athens. Hence the Athenian siege of Syracuse. After its failure, the Selinantines pressed their enemies to extremities, and so led them to call in the aid of Carthage. With this assistance they defeated the forces of Selinus in 410 B.C; and in the following spring an army of 100,000 Carthaginians, under Hannibal, son of Gisco, landed in Sicily, and before any of its allies could send succour, laid siege to Selinus. Notwithstanding a desperate resistance, the place was taken, after ten days' siege. The walls were destroyed; and though permission was given to the inhabitants to occupy the city, as subjects of Carthage, Selinus never recovered its former prosperity. During the first Punic war the Carthaginians destroyed the city, and removed its inhabitants to Lilybaeum. Selinus was never rebuilt, and its site is now completely desolate, and overgrown with brushwood. The remains of the ancient walls may be traced on a small hill near the sea, and within their limits the ruins of three Doric temples lie. Outside the walls, which enclose a comparatively small area, are traces of two edifices, whose character is unknown; and on a hill to the east stood three temples, which must have been among the largest and most magnificent in the ancient world. The place is now called *Torre dei Pulci.*

SELJOOK. See ASIA, § *Turkish Tribes.*

SELKIRK, ALEXANDER, whose adventures gave rise to Defoe's well-known historical romance of *Robinson Crusoe*, was born at Largo, in Fifeshire, Scotland, about the year 1676. He was bred a seaman, and went from England, in 1703, in the capacity of sailing-master of a small vessel, called the Cinque-Ports Galley, Charles Pickering captain. In September of the same year he sailed from Cork, in company with another ship, called the St George, commanded by the celebrated navigator William Dampier, intended to cruise against the Spaniards in the South Sea. On the coast of Brazil Pickering died, and was succeeded in the command by his lieutenant, Thomas Stradling. They proceeded on their voyage round Cape Horn to the island of Juan Fernandez, whence they were driven by the appearance of two French ships, of 36 guns each, and left five of Stradling's men there on shore, who were taken off by the French. From this they sailed to the coast of America, where Dampier and Stradling quarrelled, and separated by agreement, on the 19th of May 1704. In September following, Stradling came again to the island of Juan Fernandez, where Selkirk and his captain had a difference, which, with the circumstance of the ship's being very leaky, and in bad condition, induced him to determine upon staying there alone; but when his companions were about to depart, his resolution was shaken, and he desired to be taken on board again. The captain, however, refused to admit him, and he was obliged to remain, having nothing but his clothes, bedding, a gun, and a small quantity of powder and ball; a hatchet, a knife, and a kettle; with his books, and mathematical and nautical instruments. He kept up his spirits tolerably till he saw the vessel put off, when, as he afterwards related, his heart yearned within him, and melted at parting at once with his comrades and all human society.

Thus left sole monarch of the island, with plenty of the necessaries of life, he found himself in a situation which was hardly supportable. He had fish, goats' flesh, turnips and other vegetables; yet he grew dejected, languid, and melancholy, to such a degree as to be scarcely able to refrain from doing violence to himself. Eighteen months passed before he could, by reasoning, reading his Bible, and study, be thoroughly reconciled to his condition. At length he grew happy, employing himself in decorating his huts, chasing the goats, which he equalled in speed, and scarcely

ever failed in catching. He also tamed young kids, laming them to prevent their becoming wild; and he kept a guard of tame cats about him, to defend him when asleep from the rats, that were very troublesome. When his clothes were worn out, he made others of goat-skins, but could not succeed in making shoes, with the use of which, however, habit, in time, enabled him to dispense. His only liquor was water. He computed that during his abode in the island he had caught a thousand goats, of which he had let go five hundred, after marking them by slitting their ears. Commodore Anson's people, who were there about thirty years afterwards, found the first goat which they shot upon landing was thus marked, and, as it appeared to be very old, concluded that it had been under the power of Selkirk. But it appears by Captain Carteret's account of his voyage in the Swallow sloop, that other persons practised this mode of marking, as he found a goat with his ears thus slit on the neighbouring island of Mas-a-fuera, where Selkirk never was. He made companions of his tame goats and cats, often dancing and singing with them. Although he constantly performed his devotions at stated hours, and read aloud, yet, when he was taken off the island, his language, from disuse of conversation, had become scarcely intelligible. In this solitude he continued four years and four months, during which time only two incidents happened which he thought worth relating, the occurrences of every day being in his circumstances nearly similar. The one was that, pursuing a goat eagerly, he caught it just on the edge of a precipice which was covered with bushes, so that he did not perceive it; and he fell to the bottom, where he lay, according to Captain Rogers's account, twenty-four hours senseless; but, as he related to Sir Richard Steele, he computed, by the alteration of the moon, that he had lain three days. When he came to himself, he found the goat lying under him dead. It was with great difficulty that he could crawl to his habitation, whence he was unable to stir for ten days, and did not recover of his bruises for a long time. The other event was the arrival of a ship, which he at first supposed to be French. And such is the natural love of society in the human mind, that he was eager to abandon his solitary felicity, and surrender himself to them, although enemies; but upon their landing he found them to be Spaniards, of whom he had too great a dread to trust himself in their hands. They were by this time so near that it required all his agility to escape, which he effected by climbing into a thick tree, being shot at several times as he ran off. Fortunately the Spaniards did not discover him, though they stayed some time under the tree where he was hidden, and killed some goats just by. In this solitude Selkirk remained until the 2d of February 1709, when he saw two ships come into the bay, and knew them to be English. He immediately lighted a fire as a signal; and on their coming to shore, found they were the Duke, Captain Rogers, and the Duchess, Captain Courtney, being two privateers from Bristol. He gave them the best entertainment he could afford; and as they had been a long time at sea without fresh provisions, the goats which he caught were highly acceptable. His habitation, consisting of two huts, one to sleep in, and the other for dressing his food, was so obscurely situated, and so difficult of access, that only one of the ship's officers would accompany him to it. Dampier, who was pilot on board the Duke, and knew Selkirk very well, told Captain Rogers that, when on board the Cinque-Ports, he was the best seaman in the vessel, upon which Captain Rogers appointed him master's mate of the Duke. After a fortnight's stay at Juan Fernandez, the ships proceeded on their cruise against the Spaniards; plundered a town on the coast of Peru; took a Manilla ship off California; and returned by way of the East Indies to England, where they arrived on the 1st of October 1711—Selkirk having been absent, on the day of his arrival in London, eight years, one month, and three days, more than half of which time he had spent alone on the island. The public curiosity being excited respecting him, he was induced to put his papers into the hands of Defoe, to arrange and form them into a regular narrative. These papers must have been drawn up after he left Juan Fernandez, as he had no means of recording his transactions there. Captain Cooke remarks, as an extraordinary circumstance, that he had contrived to keep an account of the days of the week and the month; but this might be done, as Defoe makes Robinson Crusoe do, by cutting notches in a post, or many other methods. From this account of Selkirk, Defoe adopted the notion of writing a more extensive work, the famous romance of *Robinson Crusoe*. After his return to England, Selkirk waited in London till he got his effects realized, and then proceeded, in the spring of 1712, to his native village of Largo. For a few days he enjoyed the society of his relatives and friends; but, from long habit, he soon felt averse to society, and was most happy in being alone. In the upper part of the garden attached to his father's house he formed a kind of cave or grotto, which commanded an extensive and delightful view of the bay of Largo, and the shores of the Forth. In musing here, or wandering through a secluded and solitary valley called Keil's Den, and fishing in the bay, he spent the greater part of his time. How long he remained here cannot be ascertained, but he eloped some time afterwards with a girl of the neighbourhood, named Sophia Bruce, and proceeded with her to London. He never returned to Largo, and but little is known of him during the latter part of his life. Sophia Bruce appears to have died between 1717 and 1720; for in the latter year he again married Frances Candis, who survived him. Selkirk died lieutenant on board his Majesty's ship Weymouth, some time in the year 1723; and it is believed that he had no children by either of his wives. (See *Life and Adventures of Alexander Selkirk*, by John Howell, Edinburgh.)

SELKIRK, an ancient royal burgh, and chief town of the county of Selkirk, in Scotland. It is situated on an elevation overlooking the valley of the river Ettrick, 33 miles S.S.E. of Edinburgh, and commands an extensive view. It consists chiefly of one street, which expands at the market-place into an open space; in which is a fine monument and statue of Sir Walter Scott. The town has not increased in size or importance for centuries; but it has been much improved of late years, and now contains many good houses, with a town-hall, having an elegant spire 110 feet in height, and containing apartments for the burgh and sheriff courts. There are five places of worship—one belonging to the Established Church, one to the Free Church, two to the United Presbyterians, and one to the Episcopalians. A new prison has been erected at the north side of the town; and it also possesses several excellent schools, a savings bank, three libraries, and a reading-room. Selkirk was formerly famed for the manufacture of shoes, in which it had an extensive trade; but it has now no manufactures of any consequence, except those of tweeds, blankets, and hosiery; which have been recently introduced here from Galashiels. The burgh is governed by a provost, two bailies, and twelve councillors; and it votes with the county in returning a member to Parliament. During the wars between England and Scotland, the citizens of Selkirk were famed for their courage. A party of them, under the command of the town-clerk, William Brydone, fought with much gallantry at the battle of Flodden. Brydone was afterwards knighted for his conduct; and the town received from James V. a grant of a thousand acres, as a recompense for the courage of the burghers; but it was totally burned by the English, in revenge for the bravery displayed by its citizens. A mile north from the town is Philiphaugh, where the celebrated Marquis of Montrose was defeated

Selkirkshire.

by the Covenanters under General Leslie. Pop. (1851) 3314.

SELKIRKSHIRE, a county of Scotland, situated between 55. 2. and 55. 42. N. Lat., and between 2. 48. and 3. 20. W. Long. It has Mid-Lothian or Edinburghshire on the N.; Roxburghshire on the E. and S.E.; Dumfriesshire on the S.; and Peeblesshire, or Tweeddale, on the W.; the line which separates it from these counties being on all sides, but especially the south, exceedingly irregular. Its extreme length, from N.E. to S.W., is 28 miles, its extreme breadth 16, and its area 264½ square miles, equal to 169,280 English acres. It includes only three entire parishes, Yarrow, Kirkhope, and Ettrick—the parishes of Selkirk and Galashiels being partly in Roxburghshire. These may be said to form the county, although small parts of the parishes of Ashkirk, Innerleithen, Peebles, Roberton, and Stow, are also included in it.

This is almost entirely a pastoral district, and in many respects bears a resemblance to the higher parts of the contiguous county of Roxburgh. Like the latter county, the general declivity of the mountain range is from west-south-west to east-north-east, and all its streams discharge themselves into the Tweed. The rocks are of the transition series, and are chiefly graywacke, graywacke-slate, and clay-slate. On the borders of Peeblesshire extensive layers of porphyry, alternating with thin strata of slate and granite, are to be found. The hills are generally ridge-shaped, and rounded on the tops, with acclivities of from 10° to 30°. The secondary valleys are small, since the Ettrick and Yarrow run nearly parallel, and at no very great distance from each other; but where the Yarrow and Tweed diverge, the valleys increase in magnitude, as they are then drained by larger streams. Several of the hills are above 2000 feet in height—such as Windlestraw Law (2295), at the northern extremity of the county, on the confines of Mid-Lothian; Blackhouse Heights (2370); Minchmoor (2280), on the borders of Peeblesshire; and Ettrick-pen (2200), on the south-west boundary. The lower hills are for the most part green, and afford good pasturage for sheep; but heath prevails on many of the higher grounds, especially towards the south-west.

The rivers are—the Tweed, which crosses the north side of the county in its course from Peeblesshire on the west to Roxburghshire on the east; the Gala, which for some distance forms the boundary with Roxburghshire on the north-east, and falls into the Tweed, from the north, a little below Galashiels; the Cawdor, a very beautiful stream, which also joins the Tweed from the north; the Ettrick and Yarrow, which have their sources on the confines of the county of Dumfries, and, flowing north-east almost parallel to each other, join their streams above Selkirk, and afterwards, under the name of Ettrick, passing to the west of that town, and for a short distance along the boundary with Roxburghshire, enter the Tweed; the Ale, which rises in the south-east, and soon after passes into Roxburghshire; and also the Borthwick, which washes the south-eastern boundary. Next to the Tweed, the most considerable waters are the Ettrick and the Yarrow, which receive, in the first instance, nearly all the other streams that traverse this district. The scenery on the Yarrow is exceedingly romantic and delightful. Soon after its rise, it passes through two lakes, the Loch of the Lows and St Mary's Loch; the latter, which is separated from the former only by a narrow neck of level ground, is three miles long, having its banks partly covered with coppice-wood, and is the finest piece of water in the south of Scotland. From thence the Yarrow flows for eight or nine miles, through sheep-walks, without wood or cultivation; but afterwards the sides of the lofty hills in its course are covered with wood to a considerable height, and its valley is embellished with a variety of bushes and wild-flowers. Ettrick, the larger stream, has a wider and more cultivated valley; and a little before it receives the Yarrow, natural wood begins to appear on its banks. It afterwards flows for four miles through a rich tract, sheltered by plantations on the hills. From this river the whole district has been sometimes called Ettrick Forest; but the name of Forest here, as elsewhere, has long since ceased to denote the existence of extensive woodlands, of which, whatever may have been the case formerly, scarcely any traces now remain. Besides the two lakes we have mentioned, a great many smaller ones are scattered over the east and south-east quarters, of which the more considerable are Loch Alemoor, the principal source of the Ale, and Loch Oakermoor, noted for the vast quantity of marl which it contains.

This county is deficient in coal, limestone, and sandstone, and it lies under the same disadvantages as Roxburghshire, from its great distance from markets where coal and lime are to be had. The arable land lies at an elevation of from 280 to 800 feet, and does not much exceed one-tenth of the whole county. It is light, dry, and easily cultivated; and it produces wheat, oats, barley or bere, turnips, and potatoes. Wheat is regularly grown in the lower parts of the county, and even in the higher it has been raised at the height of 700 feet, yielding a good return; and it may be said that agriculture is as well understood and followed out in this as in any other of the Scotch counties. Many improvements in the mode of cultivation and the farming implements have been introduced into Selkirkshire. The houses of the tenants are now better than formerly, and the general condition of the people has been ameliorated.

The total extent of country under a rotation of crops in 1857 was 14,441 acres; of which 261 acres were occupied by wheat, 949 by barley, 4162 by oats, 29 by beans and peas, 75 by vetches or tares, 2625 by turnips, 222 by potatoes, 30 by rape, 65 by fallow land, and 6012 by grass and hay. The county is, however, on account of the dampness of the climate, more suited for pasture than for agriculture. The cattle are, for the most part, of the Teeswater and Highland breeds. Many of the sheep are black-faced, especially in the upper regions; but Cheviots and Leicesters have been introduced into the county. There were, in 1857, 763 horses, 2449 cattle, 145,732 sheep, and 474 swine—in all, 149,418 live stock in Selkirkshire. The lochs and rivers abound in various kinds of fish; pike, perch, and trout being obtained in the former, and salmon, trout, barbel, &c., in the latter. The only manufactures of the county are concentrated in Galashiels and Selkirk. Woollen fabrics are the articles principally made in both of these places. Until a comparatively late period, the county suffered many inconveniences from the want of roads; but it is now well provided for in this respect. The road from Edinburgh to Carlisle traverses the county for 11 miles; another from Glasgow to Kelso and Berwick crosses the northern portion; and others lead up the vale of Ettrick and Yarrow to Moffat. The Hawick line of the North British Railway runs for a short distance along the border of Selkirkshire; and has a station at Galashiels, from which there is a branch to Selkirk. The whole number of places of worship in Selkirkshire, according to the census of 1851, was 15; of which, 10 contained 3413 sittings. Of the former, 5 belonged to the Established Church, 5 to the Free Church, 2 to the United Presbyterians, 1 to the Independents, 1 to the Glassites, and 1 to the Evangelical Union. The number of public schools at the same date was 15, and of private schools 9. The number of proprietors in the county is 498; and the valuation of rental for 1857–58 was L.61,028. One member is returned to Parliament, by a constituency amounting in 1858 to 861.

The country now occupied by Selkirkshire formed, in the earliest historical period, a part of the territory of the Gadeni. It was occupied by the Romans during their

possession of our island; and after their departure was overrun by the Anglo-Saxons. At that time, however, it was covered with dense forests, and had few settled inhabitants. Very few remains of the Roman or Saxon times have been preserved in Selkirkshire. When the southern part of Scotland was given up by the Anglo-Saxon kings of England, Selkirk was frequently a residence of the Scottish monarchs; and the county was formed probably about the reign of Alexander II. In the fifteenth century it belonged principally to the Douglas family. The largest proprietor now is the Duke of Buccleuch, to whom about two-thirds of it belong. The principal seats in the county are—Thirlestane, belonging to Lord Napier; Ashestiel, once the residence of Sir Walter Scott, now belonging to Sir James Russell; and Borthwickbrae, to A. E. Lockhart, Esq., M.P. There are several old castles, the chief being that of Newark, near Selkirk, the scene of the *Lay of the Last Minstrel*. The most distinguished natives of Selkirkshire have been Mungo Park, the African traveller, and James Hogg, the Ettrick Shepherd. Pop. of the county, (1801) 5388; (1811) 5889; (1821) 6637; (1831) 6833; (1841) 7990; (1851) 9797.

SELLASIA, an ancient town of Laconia, in the valley of the Œnus, at the point where the roads from Sparta to Argos and Tegea separate. It is only remarkable for an important battle that was fought here B.C. 221. During the war between Sparta and the Achæan League, the latter having obtained the assistance of Antigonus the Macedonian monarch, Cleomenes, king of Sparta, apprehending an invasion, took up a strong position near Sellasia with 20,000 men. His right wing, under his own command, occupied Mount Olympus, and his left, under his brother Eucleidas, Mount Evas; while the whole line was defended by intrenchments. Antigonus approached from the north with a much superior force; but seeing the strength of his adversaries' position, hesitated for some days before venturing an attack. At length he assaulted with his right wing the position of Eucleidas; and, favoured by an error of that general, and a timely charge of Philopœmen with the Megapolitan cavalry, gained a complete victory. Cleomenes then advanced to retrieve the day; but, after a desperate conflict, was repulsed with great loss. Antigonus thereafter captured Sparta, and Cleomenes took refuge in Egypt.

SELVA, a town of Spain, Catalonia, in the province and 9 miles N.W. of Tarragona. It stands in a fertile plain; and contains two churches, two suppressed convents, potteries, oil-mills, and distilleries. Pop. 4250.

SEMENDRIA, or SMEDEREWO, a town of European Turkey, in Servia, on the right bank of the Danube, 24 miles S.E. of Belgrade. It is fortified and defended by a citadel. Formerly the residence of the kings of Servia, Semendria is still the seat of a bishop. On the hills that encircle the town to the S. and S.W. lie many vineyards, celebrated for the excellence of their grapes and wine. Fishery, trade, and navigation, are carried on here. Pop. (1854), exclusive of the Turkish garrison, 3829.

SEMI-ARIANS, a branch of the ancient Arians, who arose during the fourth century, and denied the consubstantiality (ὁμοούσιον) of the Son with the Father, but admitted their (ὁμοιούσιον) similarity of substance. The leaders of this party were George of Laodicea and Basil of Ancyra.

SEMICIRCLE is that figure which is comprehended between the diameter of the circle and half its circumference.

SEMICOLON. See PUNCTUATION.

SEMIDIAMETER, half the diameter or radius of a circle.

SEMIPALATINSK, or SEMIPOLATINSK, a district of Asiatic Russia, bounded on the north by the government of Tomsk, E. by Chinese Songaria, S. by Independent Turkestan, and W. by the Kirghise lands. Area, 164,682 square miles. Almost the whole of the district, especially the east and south-east portions, is traversed by lofty ranges of mountains, those towards the north being offshoots of the Altai Mountains, and those towards the south, of the Mustagh or Thian-Shan range. The names of the principal chains in the district are the Kalbin-Tagh, Tchingis-Tagh, Ala-Tagh, and Tarbagatai. Numerous rivers rise in these mountains, and flow in all directions. The chief of these are the Irtish, an affluent of the Obi; the Ili, which flows into Lake Balkhash; the Tchar-Gurban, falling into the Irtish; the Tjunduk, the Aisi-Su, the Kokbekty, the Bakanas, and the Ajagus. There are also many lakes in the district; of which the largest are Balkhash, Issik-Kul, Sasyk-kul, Ala-Kul, and Saisan. Lake Balkhash and the Ili are navigated by steam-vessels. The country is chiefly inhabited by Kirghises of the Great and Middle Hordes, and by Russians; to whom there have been added, in recent times, a people who conceal their origin, but call themselves *Tchala Asaki*, or wanderers from Central Asia. There are also a number of merchants from Kazan, Troizk, and Petropaulowski; and many strangers from the adjacent countries of Central Asia. The chief occupation of the settled population is the keeping of cattle and sheep; the Kirghise, on the other hand, live by hunting and fishing. At some places in the district there have been established gold washeries, silver mines, lead and copper works. An important trade is carried on through the districts by means of caravans, which proceed along the roads that traverse the country in different directions. On some of these there have been erected post-houses and inns for the convenience of travellers. Cotton fabrics, cloth, metals, and furs, are exported from Russia to Turkestan and Songaria, in exchange for raw silk and cotton, carpets, tea, &c. Semipolatinsk was erected into a district in 1854. It is divided into four circles, and had in 1851 a population of 121,300; though at present it is much more populous.

SEMIPALATINSK, the capital of the above district, on the right bank of the Irtish, 400 miles S.S.E. of Omsk. It is a fortified place, in the midst of a fertile plain covered with gardens; and derives its name, signifying "the seven palaces," from certain buildings which the Russians found there on the conquest of Siberia. Many of the inhabitants are employed in fishing; and a considerable trade is carried on. Pop. (1850) 7593.

SEMI-PELAGIANS, a sect who differ from the Pelagians in maintaining the necessity of divine grace towards the saving of the soul; but conceive, at the same time, that this grace may be obtained by an effort of the will. (See PELAGIUS.)

SEMIRAMIS, queen of Assyria, reigned about five generations before Nitocris, and constructed some wonderful works to restrain the waters of the Euphrates within its banks. Almost everything known regarding her is bound up with fable; and except the fact that she was the founder of the Assyrian monarchy, everything else is open to doubt. Diodorus gives a more detailed account of her, which is copied principally from Ctesias. Omitting the fabulous statements respecting her youth, we there find that she had a son, Ninyas, from Ninus; and that after her husband's death she thought herself capable of governing the empire. She founded the city of Babylon, which she surrounded by walls of immense strength, and adorned by very wonderful buildings. On the top of the temple of Belus she placed three statues of massive gold, and from the middle of the temple rose a tower higher than the highest pyramid of Egypt. Some have thought that this was the tower of Babel. She made warlike expeditions against the Medes, Persians, Libyans, and Æthiopians. She is said to have executed many wonderful works in

different parts of her kingdom, changing mountains into plains, and constructing canals and palaces. Hearing of the riches and power of India, she determined to make war on that kingdom, and prepared an immense army; but she was in a great measure unsuccessful, and returned with the loss of nearly her whole army. When she reached Babylon, her son laid snares for her; and as it had been predicted by the oracle of Jupiter Ammon that she would disappear from the world when this took place, the prediction was fulfilled. Semiramis was no more seen, having died in the sixty-second year of her age, and the forty-second of her reign. Such is the common account of Semiramis. Much of it is doubtless fabulous. The Semiramis of Herodotus (i. 184) is palpably different from the Semiramis of Ctesias. Some connection, however, is supposed to exist between the queen and Nabonassar, as well as between her and Pul. (See Rawlinson's *Herodotus*, vol. i., p. 50; also, Colonel Sir H. Rawlinson's communications to the *Athenæum*, Nos. 1377 and 1381.) Cuneiform inscriptions found at Wan, which is called by the Armenians "the City of Semiramis," are said to relate to the history of the Eastern queen. As these inscriptions are now being recovered and placed in the British Museum, they will no doubt ere long be deciphered and made public by a highly competent translator.

SEMITONE. See Music.

SEMLER, Johann Salomon, a theological writer of considerable influence in Germany during his day, was born at Saalfeld on the 18th of December 1725. He was the son of an archdeacon of Saalfeld, and was early initiated into the doctrines of the Pietists, which, however, he ultimately exchanged for the rising Rationalism of the time. He was educated at Halle, where he greatly distinguished himself, and was appointed to a professorship at Coburg in 1749. Next year he was made editor of the *Coburg Zeitung*, and was removed to Altdorf as professor of history and poetry. He was chosen, in 1751, professor of theology at Halle, where he delivered a course of exceedingly popular lectures, betraying extensive reading, but deficient in order and arrangement. In 1757 he was made director of the theological seminary, which he held till his dismissal in 1779 by the minister Zedlitz. He spent much of his time in theological controversy, and attacked his opponents with considerable bitterness. His adoption of the Prussian edict regarding religion, in 1778, exposed him to the charge of inconsistency, and embroiled him in unceasing feuds, which were ended only with his life. He died on the 14th of March 1794. Semler was an industrious writer, and produced numerous works during the course of his life, of which the principal are his *Abhandlung von der Untersuchung des Canons*, 4 vols. 1771; *Apparatus ad Liberalem Veteris Testamenti Interpretationem*, 1773; *Institutio ad Doctrinam Christianam*, 1774; *De Demoniacis*, 1760; *Umständliche Untersuchung der dämonischen Laute*, 1762; *Versuch einer biblischen Dämonologie*, 1776; *Selecta capita Historiæ Ecclesiasticæ*, 1767–69; *Commentationes Historicæ de Antiquo Christianorum Statu*, 2 vols. 1771–72; *Versuch Christlicher Jahrbücher*, 2 vols. 1783–86; *Observationes Novæ*, 1784; and his *Autobiographie*, 2 vols. 1781–82.

SEMLIN, or Zemlin (Hung. *Zimony*), a town of the Austrian empire, in the Military Frontier, on the left bank of the Danube, just above its confluence with the Save, on the other side of which stands Belgrade on Turkish ground. It consists of an inner town, and a suburb called Franzenthal. The former contains some good streets and substantial houses; but the place, as a whole, is mean and wretched, especially the quarter called Zinkaberg, which is inhabited by gypsies. Among the edifices are five Roman Catholic and two Greek churches, a synagogue, an hospital, a theatre, and several schools. Semlin has a very important trade, as it is the great emporium for commerce between Turkey and the Austrian empire, and the principal quarantine station on the frontier. Woollen cloth, porcelain, and glass are sent to Turkey; and yarn, leather, skins, honey, and meerschaum-pipes obtained in return. The town is fortified, and is occupied by a military community, consisting chiefly of Slavonians, Croatians, Servians, and Greeks. Pop. 12,978.

SENAC, Jean Baptiste, called also by Haller, in his *Bibliotheca Anatomica*, Pierre, a distinguished French physician, was born in the diocese of Lombez in 1693. Having taken his medical degree at Rheims, he subsequently practised physic with great applause. He was made first physician to the king in 1752, and a member of the Royal Academy of Sciences of Paris. In addition to his contributions to the *Mémoires de l'Academie*, which began as early as 1824, he likewise published anonymously a *Traduction* of the *Anatomie* of Heister, with additional *Essais de Physique sur l'Usage des Parties de Corps Humain*, Paris, 1724, 1735, 1755, 3 vols. 12mo. His next work, which appeared under the assumed name of Julien Morrison, entitled, *Lettres sur le Choix des Saignees*, Paris, 1730, had great sale. His *Traitê de la Structure du Cœur*, 2 vols. 1748, was regarded as his greatest work, and has been since published at Paris, with additions and emendations by M. Portal. He likewise published another book full of profound knowledge, *De Recondita Febrium Natura et Curatione*, 1759.

SENATE (*Senatus*, from *senex;* Γερουσία from *γέρων, a man advanced in years*), in all the republics of antiquity, was an assembly of the elders, chosen from among the nobles of the nation. This was the meaning borne by the ancient Roman senate, and it was likewise the signification of the Spartan *γερουσία*. In the old republics, the number of senators always bore a determinate relation to the number of tribes included under the nation. Thus, when Attica was divided into four tribes the number of senators was 400; and when Cleisthenes increased the tribes to ten, he made the number of senators 500. When Rome, in very early times, consisted of but a single tribe, the Roman senate consisted of 100 members; and when, by the addition of the Sabine tribe, the nation became increased, the senate then consisted of 200 members. Again, when the Luceres became incorporated with the Roman state, the Roman senate was increased threefold, and numbered 300. Tarquinius Priscus, who added new senators to the old assembly, distinguished between those of his own formation, and those who had held office before, by designating the former by the appellation of *patres minorum gentium.* Under Tarquin the Proud, the senate is said to have been greatly diminished by the death and exile which the tyrant sent into their ranks. (See Niebuhr's *Hist. of Rome*). The vacancies thus occasioned were subsequently filled up by noble plebeians of the equestrian rank; and hence they bore the designation of conscript fathers, or of *patres et conscripti.* The numbers being thus raised again to the original 300, the senate remained for many centuries altogether unaltered.

A change of some kind was proposed on the number and the constitution of the senators, by C. S. Gracchus, but of what precise kind does not appear. Under the tribuneship of Livius Drusus, 300 equites were added to the original senate, which swelled out its numbers to 600. This law was abolished, however, by the senate itself on the death of its originator, and its numbers again stood at the old figure of 300. Vacancies occurred during the progress of the civil war between Marius and Sulla; and it is supposed that the latter raised the Roman senate to between 500 and 600. (Cicero *ad Att.* i. 14). The first of the Cæsars raised their number to 900, and exalted to the dignity common soldiers, freedmen, and peregrini. (Suetonius, *Cæs.* 80.) This opening

Senate.

of the door to the vulgar was imitated after Cæsar's death, when the senators seem to have been augmented to the number of 1000. Augustus cleared the senate of these *Orcini Senatores*, as they were called (Suetonius, *Aug.* 35), and limited their number to 600, which seems to have continued constant during the early centuries of the empire. The number of senators must have been greatly diminished during its latter years. The several periods of the history of Rome afforded progressive changes in the election of persons to the senatorial dignity. It was an old opinion, founded on a passage in Livy (i. 8), and another in Festus (*Præteriti Senatores*), that in the early period of the history of the Roman people, the choice of senators lay exclusively with the kings. Niebuhr (*Hist. of Rome*, i.) has cast doubt on this belief, without being able to substantiate the conviction to which he adheres—namely, that the *populus* was the sole power, who chose kings and senators alike to act as their representatives in the high councils of the nation. Almost all the old authorities adhere to the opinion that the senators were chosen by the sole voice of the king, and their testimony cannot be fairly set aside on such slender evidence as Niebuhr employs. Nothing more is known respecting the time of life at which a man could become a senator during the kingly period than is specified by the title itself (*senator*, from *senex*); that is, that he must be advanced in years. A man could not become a senator most probably before the age of thirty-two. The age was finally fixed by Augustus at twenty-five, which seems to have continued the law throughout the entire existence of the empire. The senate itself seems to have had some voice in the election of members to join its body, for we find it raising objections against a person just elected (Dionys. vii. 55). The entire senate was divided into decuries, each of which corresponded to a curia. Originally, when the senate consisted of 100 members, there were in all ten decuries, and one senator chosen from each decury made ten senators, which constituted the *decem primi*, who represented the ten curies, and who gave their votes first. The principal senator was chosen by the king, and was the first among the *decem primi* to give his vote.

On the establishment of the republic at Rome, the election of senators, which had hitherto rested with the king, fell to the magistrates, consuls, consular tribunes, and finally to the censors (Livy ii. and Festus, as above). The censors had the sole power to choose or refuse new members to the senate, from among the ex-magistrates, from the institution of the censorship in Rome. We must likewise distinguish between real senators and official senators, or those who merely took their seats in the senate-house, and were permitted to speak but not to vote. These were the persons who held the office of curule magistrate. (Gellius, iii. 18; Festus, *Senatores*). The senate-house was now gradually changing its character into a popular assembly. From the time that the public and private offices of state became equally accessible to plebeians as well as to patricians, the senate gradually changed, until in a short time the dignity was regarded as one that properly belonged to the *populus* to confer. Yet it did not degenerate into a mere democratic gathering; for its members of all classes belonged to the *nobiles*, whether they were of plebeian or patrician origin. The office of *princeps senatus* was usually given to the oldest ex-censor, or to any other on whom their electoral regards happened to alight. The fixing of a definite income for senators was limited entirely to the age of the empire. Augustus first laid it down at 400,000 sesterces, and subsequently it rose as high as 1,200,000 sesterces. Those senators who were found deficient, received grants from the emperor, and those who had wasted their estate by vice and prodigality were sternly reminded that their presence could thereafter be dispensed with. No senator was permitted to engage in any mercantile pursuit, although it is plain from what is recorded by Cicero (*Verres*, v. 18) that this law was often violated. A new element was likewise introduced into the senate by the admission of municipal, colonial, and provincial functionaries. These officials, of course, were required to fix their residence at Rome, or in some part of Italy; and they were not permitted to remove to their native districts without special permission from Augustus, or from the reigning emperor. Regular meetings of the senate took place on the calends, nones, and ides of each month. The right of convocation was limited during the monarchical period to the king or the *custos urbis*; during the republic it was extended first to the curule magistrates, and subsequently to the tribunes; during the empire it was confined to the emperor, and was likewise dispensed to the consuls, prætors, and tribunes. The places where the senate held their meetings were always opened by the augurs. The most ancient senate-house was the Curia Hostilia; and during the successive changes which the government of the country underwent, it was transferred to different buildings, until at last it was by no means uncommon to find it held in the house of the consul. During the early history of the senate the patrician power was quite unlimited, except by the kingly authority; and when a perfect equality came at length to be established between the patricians and the plebeians, the Roman senate witnessed its best days of freedom. Under the despotic government of the emperors, which succeeded, it became the plastic tool of the *princeps senatus*, who was very commonly the emperor. And not only did the emperor gather up into his own hands all the power formerly possessed by the magistrates, he likewise controlled, in the most absolute and irresponsible manner, all the deliberations and all the determinations of the senate.

Under the palmy days of the Roman senate, that body had the supreme superintendence of everything connected with religion, war, and finance. It decreed to what provinces consuls and prætors were to be sent. It determined what commissioners were to be despatched from Rome to settle the administration of a newly acquired country. It settled all treaties of peace, and other political negotiations, between the parent country and other foreign states. It took special cognizance of all crimes, such as treason, conspiracies, poisoning, and murder. It gave and received the representations of ambassadors, and heard the complaints of subject or of allied nations. In short, everything, whether within or without the republic, of which Rome chose to take cognizance, was committed to the care of the senate. A decree of the senate was called a *senatus consultum*. When Byzantium was made the second capital of the Roman empire, a second senate was likewise instituted there as well as at Rome, and continued to perform its part in the legislation of the empire down to the ninth century.

The more distinguished badges and privileges enjoyed by the Roman senators were as follows:—The tunica, with a broad purple stripe in front; and a short boot, with the letter C on the front of the foot, supposed to be the initial of the word *centum*, in allusion to the early senate of Rome, which consisted of 100 members; the right of occupying the orchestra of theatres and amphitheatres; the right of a senatorial feast, when the public sacrifice was offered to Jove in the capitol; and the right of free embassage (*libera legatio*), made up the whole of the more important benefits enjoyed by the senators of Rome.

Seneca.

SENECA, M. Annæus, a famous rhetorician, father of the philosopher. He was born in the old and flourishing colony of Corduba, in Spain, a country which at this time exercised a powerful influence on the politics and literature of Rome. His family was of equestrian rank, and had never attained to any of the curule honours (Tac. *Ann.*) Whether

the gens Annœa was of Spanish or Italian origin, and whether the names Annœus and Seneca have any connection with the words "aunus" and "senex" (as Lipsius thinks), is uncertain. Clinton places the date of Seneca's birth about B.C. 61, as may be inferred from his own statement, that but for the civil wars he might have heard the eloquence of Cicero, who was the only great orator of that day to whom he had not listened.[1] After spending some time at Rome, and making acquaintance with many of his most eminent contemporaries, he returned to Cordova, and married Helvia, a Spanish lady of amiable character and great accomplishments. By her he had three sons, all of whom acquired great celebrity—viz., Novatus, the eldest, who afterwards took the name of Junius Gallio, and on whom the Christian world has bestowed an unenviable notoriety, by proverbially misapplying an expression of St Luke;[2] Seneca, the philosopher; and Mela, the father of the poet Lucan. After a sojourn in Spain, he once more went to Rome with his family; and no further particulars are known about him, except that he lived in wealth and reputation, probably till the close of the reign of Tiberius.

Parts of two works written by Seneca in his old age are extant—the *Controversiæ* and *Suasoriæ*. Both of them are collections of mere rhetorical exercises; the first on imaginary cases, such as might have occurred in real life; the second on historical events and circumstances in the lives of great men. As literary productions they are nearly worthless, in spite of the author's retentive memory and polished style; they are only valuable as indications of the temper and taste which began to be prevalent in the early days of the empire. The greatest minds, debarred from the real eloquence which is only compatible with political freedom, sought some rest for their wounded spirits in the "resigned yet militant" philosophy of the Porch—a philosophy which, as has been well remarked, "almost enveloped its votaries in an atmosphere of Christianity." But those who, like M. Annœus, despised or disliked[3] philosophical pursuits, were forced to take refuge in oratorical puerilities, the practice of which gave them a mechanical facility which they mistook for fluency, and a verbiage which they confounded with eloquence. We have, however, in the elder Seneca, only the germs of that affected style which afterwards characterized the silver age of Roman literature. He is not, indeed, entirely free from the growing degeneracy; but he belonged to another period, and remembered a better taste.[4]

The best edition of the *Suasoriæ* and *Controversiæ* is that of Andr. Schottus, Paris, 1607, which contains all the notes of N. Fabrr, Gruter, Lipsius, Opsopæus, &c. (F. W. F.)

SENECA, *L. Annæus*, the most prominent and interesting man of his time, was the second son of Seneca the rhetorician. He was born at Cordova, B.C. 3 (about the same time as the Apostle St Paul), and brought to Rome by his family when an infant in arms.[5] From the first he was of a feeble constitution. His life, like that of Pope, was "a long disease;" and he was liable from infancy to nervous shivers, asthma, fever, and fainting.[6] But in a delicate and languid body lived a daring and restless soul, to which, perhaps, his Spanish descent had given a touch of "phantasy and flame." The intense and characteristic ardour of his studies tended still more to undermine his health. Although his father mainly urged him to the pursuits of rhetoric, philosophy attracted him with superior charms; and he gladly turned from the dull platitudes of artificial eloquence to the spiritual guidance of Demetrius the Cynic, and Sotion the Pythagorean. He found a sublime pleasure in carrying their precepts into daily practice; like Attalus, he learned to lie on a hard mattress, and like Sextus he became a vegetarian in diet and subjected himself to daily[7] self-examination. The worthy rhetorician, his father, regarded these vagaries of philosophic asceticism with strong intellectual dislike; but he persuaded Seneca to abandon them, rather on the ground that they laid him open to the suspicion of adopting those oriental superstitions the proselytes of which had recently been banished from Rome by an edict of Tiberius. Seneca, however, never quite forgot the Stoic precepts of temperance and sobriety. In the bosom of opulence he remained an enemy of the Ionian luxuries of baths and perfumes; he slept lightly, and drank but little wine; and whatever may have been the value or splendour of his 500 cedar and ivory-footed tables, they were rarely spread with any entertainment more sumptuous than water, vegetables, and fruit.

Turned by filial respect into less congenial pursuits, he threw his whole mind into public and forensic duties. He was elected quæstor, and soon won a brilliant reputation at the bar. His fame and ability excited the jealousy of the Emperor Caligula, who himself pretended to eloquence, and had a deadly hatred of superior genius. Domitius Afer had already saved himself from the tyrant's spiteful fury, by an acknowledgment of inferiority.[8] Seneca only owed his life to his ill health; for Caligula was assured by one of his mistresses that so sickly a subject could not last long. The emperor accordingly contented himself with contemptuous descriptions of Seneca's style, which he called "sand without lime."[9]

Forced by this danger to change his plans, Seneca once more began to devote himself to philosophy, and mastered with great assiduity the voluminous treatises of Plato, Aristotle, Zeno, Chrysippus, and Epicurus. This was probably the period of his greatest intellectual activity, because he was living in the closest intercourse with all the literary men of the day, undisturbed by any public or professional duties. If he ever travelled in Egypt, where his uncle had been præfect for sixteen years, it must have been about this time. But the journey is very doubtful; and the fact that he travelled at all, although eagerly believed by those who wish to attribute some of his knowledge to Jewish or Christian information, is a mere precarious inference from the title of a lost treatise on India.[10]

Upon the death of Caligula, Seneca was free to resume his political ambition, but a sudden check was put to his splendid career. He was accused of adulterous intercourse with Julia, the beautiful and infamous sister of the late emperor, whom Claudius had recalled from her banishment in the island of Pontia. The charge was brought by Messalina, who both hated and feared her haughty kinswoman; but the guilt of the accuser is not sufficient to exonerate Seneca from participation in the crime. Because Messalina was a licentious and cruel woman, it does not follow that Seneca was an innocent man; and it seems to us unlikely that he should have been fixed upon for punishment, without some adequate grounds of suspicion. Considering the weakness, the deplorable weakness, of Seneca's character, the laxity of the age in such matters, and the certainty that this and similar charges[11] clung to him through life, there is reason to fear his guilt. We do not think that this would have deterred such a woman as Agrippina from subsequently making him the tutor of Nero. Even in the nineteenth century, and in Christian countries, we do not find men precluded from filling the most exalted and responsible stations from the notoriety of their immoral lives.

Seneca.

Claudius appears to have mitigated[1] the original severity of the sentence passed by the senate, and Seneca was banished to the island of Corsica, without any confiscation of his property (B.C. 41). Barbarous, and savage, and terrible as the rocks of Corsica appeared to the exile, this eight years' banishment was to him an unmixed blessing, and was the period of his life on which we can dwell with the most pleasure. It mollified the virulence of the envious, and excited the compassion of the good; it increased his real reputation, while it diminished his obvious dangers. Above all, it gave him a season of calm and safety for the growth and nurture of his character and genius. In the intoxication of prosperity and power, he never forgot the sobering lessons of humiliation and misfortune; and perhaps, while the seas and stars and winds were supplying food for his philosophic contemplation, he was nearer happiness than while he was the prey of anxiety and suspicion in the midst of gardens and villas that an emperor might have envied.

Two works, which resulted from his residence at Corsica, are extremely curious illustrations of his wavering impulses, the *Consolatio ad Helviam* and the *Consolatio ad Polybium*. The former was written to comfort his mother with the thought that he was raised by the study of philosophy above the need of pity. He eloquently praises the glories of nature, and the delicious reveries of intellectual solitude; and some, at least, of his arguments bear the impress of sincerity. Yet, in the *Consolatio ad Polybium*, he implores an unprincipled freedman to procure his acquittal even at the cost of his character, and he endeavours to gain the repeal of his sentence by the grossest adulation to the "divine and merciful" emperor. The admirers of Seneca have always wished to prove this work spurious; but it is merely another example of a fact which is sufficiently obvious to any impartial judge, that Seneca was a philosopher in name alone. Let us remember, too, that such language, however little it could have been used by a Thrasea or an Helvidius, was all but universal in that enslaved, degraded age. It meant a great deal less than it seems to mean; and such epithets conveyed quite as little impression of flattery to a Roman ear as our own terms "religious and gracious," when applied to a Charles II. or a George IV.

We now come to the third stage of Seneca's eventful life. Messalina being dead, her successor Agrippina determined, by a stroke of policy, at once to gain a first-rate adviser and to secure popular applause, by persuading the easy emperor to recall the philosopher, elevate him to the prætorship, and make him the tutor of the young Nero (A.D. 49). Seneca was not superior to the splendid temptation of such a proposal, though, even with *his* marvellous reputation, he could hardly have hoped for much legitimate influence in such a court, composed as it was of an uxorious dotard, insolent freedmen, and licentious women. He may have had an honest desire to serve his generation, or he may have been unable to decline the proffer; but at any rate he must have been aware, that in undertaking the duties of the position, he was entering a region perilous alike to his rectitude and his peace.

From this time the biography of Seneca must assume the form of an apology rather than of a panegyric. The philosopher is merged in the courtier, and we see the Stoic transformed in his public life into a minister both supple and complaisant. The "comitas honesta" which Tacitus attributes to him can only be an euphemism for unworthy subservience. It was, perhaps, impossible for him to instil anything noble into the weak and degraded mind of Nero; but Seneca must certainly incur the blame of signal failure in the management of his pupil. A loose and ignorant youth, initiated from infancy into all the mysteries of iniquity, the son of vile parents, and the heir to boundless expectations, was not likely to become either wise or good. But if Seneca had guided him with a firmer will and a stronger hand, might he not have been saved from developing into a monster? If Nero had seen in his tutor a man of high aims and stainless integrity, is it possible that he could ever have formed a cherished[2] belief that all men, however successful their hypocrisy, were at heart as degraded and as infamous as himself? The treatise which Seneca addresses to him on clemency, and the appeal,[3] in which he reminds his pupil of past expostulations, are indeed proofs that the philosopher could give admirable advice in a graceful and dignified manner; but advice alone, even when accompanied by good example, would have been as ineffectual with Nero as it was with the sons of Eli; and, unhappily, it will be seen that Seneca, while yielding to the pleas of expediency, belied the precepts of his philosophy in the weakness of his life.

No sooner was Claudius poisoned than Seneca wrote the flowery official oration in which Nero pronounced his funeral eulogium, and a satire against his foibles, overflowing with the deadliest contempt. It is possible that the oration, which was received with laughter, was merely an audacious piece of irony. The satire has come down to us, and displays the "divine and merciful" emperor in all his wretchedness. The very name[4] by which it was commonly known conveys the bitterest sarcasm; it involves a comparison between Claudius and one of "those bloated gourds which sun their speckled bellies before the doors of the Roman peasants." His deification, according to Seneca, should have been called gourdification. "The senate decreed his divinity; Seneca translated it into pumpkinity."[5] This fragment of antiquity is very curious and interesting: it begins with spattering mud on the despised memory of the divine Claudius; it ends with a shower of poetic roses over the glory of the diviner Nero!

It was a terrible court for a Stoic to live in. Seneca and his somewhat stolid, but far more virtuous, colleague, the soldier Burrus, had to combine their courteous wisdom and military bluntness, in order to check at once the insolent ambition of Agrippina and the mad passions of her son. Whatever may have been Seneca's public obligations to Agrippina, or his private intrigues with her, he sided unhesitatingly with Nero. At first the new government gave an illusory hope of justice and clemency. Nero delivered many harangues full of promise, which it was well known that Seneca had written, either, says Tacitus, "to prove[6] that his counsels were beneficial, or to show off his intellectual power." We might have hoped that Seneca had a nobler object in view, but it is sad to find that Tacitus gives no hint of it; and we cannot but fear that he had far more accurate means of estimating the character of the philosopher than we can pretend to have. Seneca did, however, succeed for a time in restraining the savage canine nature of his pupil from the taste[7] of human blood. He was less successful in governing Nero's licentiousness, and was forced not only to connive at, but even to encourage the youth's unworthy amour with the freedwoman Acte.

Blacker events followed. Nero murdered his young and innocent brother, Britannicus, and Seneca was more than suspected of having had his share of the largesses by which the murderer sought to remove the odium of the[8] deed. Nor must we forget that the treatise *de Clementia*, in which he expresses such hysterical admiration of the young em-

peror's goodness of heart, was written after the commission of this most atrocious crime. Nero next caused the assassination of his mother, and Seneca, even if ignorant of the first attempt upon her life, of which Dion[1] Cassius charges him with being the instigator, was the first to break the hideous silence,[2] in sanction of the expediency which demanded the completion of the murder. Besides this, he was the author of the letter in which Nero at once blackened his mother's memory, and gave an account of her death too ridiculously false to gain a moment's credence. It is awful to think of this patron of virtue sitting down to adorn with his usual[3] graces of style the defence of an incestuous matricide, by imputations which he knew to be groundless and an assertion which he knew to be a lie.

In spite of the dark whispers of the people, and the open charges which had been brought against him by[4] Suilius, Seneca was now at the summit of his fame. His overgrown wealth was the reward of his guilty connivance. Two of his greatest contemporaries, Juvenal[5] and Tacitus, call him "prædives," "the too wealthy." His enemies accused him of increasing this wealth by the basest arts of the legacy-hunter and the parasite; but even if this be false, he certainly did increase it by enormous usury, which "exhausted Italy and the provinces." Dion,[6] who omits no opportunity of aspersing his memory, even accuses him of having caused the war with Britain, by suddenly recalling the enormous sum of 4,000,000 sestertii. The terms in which he himself alludes to his income leave no reason to doubt that it amounted to 300,000,000 sestertii, and his single[7] defence, that he owed it all to Nero's bounty, is very lame and unworthy. His wealth was unquestionably dishonourable to him. "The business of a philosopher," says Lord Macaulay,[8] "was to declaim in praise of poverty with two millions sterling out at usury, to meditate epigrammatic conceits about usury in gardens that moved the envy of sovereigns, to rant about liberty while fawning on the insolent and pampered freedmen of a tyrant, to celebrate the divine beauty of virtue with the same pen that had just before written the defence of the murder of a mother by a son."

His riches hastened his ruin. Burrus died, perhaps by poison, in A.D. 63, and was succeeded by Rufus and Tigellinus, both of whom excited the jealousy and suspicion of Nero against the hated philosopher. Feeling his danger, he demanded an interview with the emperor, and begged leave to resign his vast possessions, and after his fourteen years of service, to retire into private life. Nero declined the offer with treacherous caresses, and the strongest asseverations of regard; but Seneca, under the pretence of study and ill health, withdrew from affairs of state, reduced his princely establishment, and avoided publicity by every means in his power.[9]

Not long after, when Nero began to add sacrilege to his other crimes, Seneca once more asked permission to leave Rome, and, on a second refusal, feigned a severe illness, and confined himself to his chamber. It was thought that an attempt of Nero to poison him by the instrumentality of his freedman Cleonicus, was only defeated by the confession of the accomplice, or by the abstemious habits of the philosopher, who now took only bread and fruit as his food, and quenched his thirst only out of the running stream.[10]

Under circumstances such as these, we should hardly be surprised if he turned conspirator. His popularity and wealth made him not only a tempting prey, but a dangerous and dreaded rival. Even in A.D. 63, he had been suspected of a treasonable correspondence with Piso, and in A.D. 66, he was actually charged with a knowledge of Piso's political intrigues. The evidence brought against him was of the feeblest character, but there was a report to which Juvenal,[11] as well as Tacitus, seems to allude, that Subrius Flavus had, with Seneca's knowledge, entertained a design of murdering Piso, in case of his conspiracy succeeding, and of then offering the imperial power to Seneca himself. The rumour is at least a proof of Seneca's dangerous popularity; and Nero, long disgusted by the tacit reproach of his hated tutor's mere existence, determined, with great alacrity, to get rid of him. After giving a futile hint, the tribune Granius Sylvanus was sent expressly to command his suicide. Seneca was supping with his young wife Paulina in a villa five miles from the city, and not being allowed to see his will, prepared at once to put the order of death into execution, consoling his friends with the too complacent observation, that he would at least leave to them the legacy of a noble example. Checking their tears and lamentations, and reluctantly yielding to his wife's[12] desire to share his death, he caused his own veins and those of Paulina to be opened at one blow. His blood flowed so slowly, in consequence of age and feebleness, that it was afterwards necessary to open the veins of his legs; and his torments were so prolonged and excruciating that he was forced to separate from Paulina, in order to spare her the pain of witnessing them. Paulina's life was saved by the order of Nero, though her white face showed ever after how much she had endured. Meanwhile, Seneca having swallowed in vain a draught of hemlock, was placed in a warm bath, and as he entered it, sprinkled his slaves with the water, saying, that it was a libation to Jupiter the Liberator. Finally, growing impatient of the useless agony, he was carried into a sudatorium, and stifled by the warm vapour A.D. 65. He was at this time about seventy years of age. His friends afterwards published the eloquent messages which he had delivered to them during his dying moments, and which they had taken down at his own request. His body was privately burned without any ceremony, according to the directions which he had left in his will, written in the days of his prosperity and power.

Lipsius and others have made the character of Seneca a theme for extravagant admiration; but they do so by omitting all those black and ugly particulars which mark the period of his elevation. So admirable is his theoretic morality, that the forged correspondence between him and St Paul was long accepted as genuine, and on the strength of it he has been quoted as an authority by fathers and councils, and almost spoken of as a Christian by Tertullian and St Jerome.[13] Yet, at the best, his life is a melancholy spectacle; it was one long conscious inconsistency; one continual surrender of real duty to fancied expediency. Some of his worst acts may find a parallel in the lives of greater and better men; but his defence of Nero's matricide is many shades more disgraceful than Bacon's apology for the execution of Essex, or Milton's arguments for the murder of Charles I. Even if we judge him, independently of his philosophic pretensions, he presents a somewhat despicable appearance. Niebuhr's judgment of him is quite just. "He was an accomplished man of the world, who occupied himself very much with virtue, and may have considered himself to be an ancient stoic. He certainly believed that he was a most ingenious and virtuous philo-

[12] Dion's account, as usual, has a more malignant colouring (lxi. 10; lxii. 25); but in this instance his calumnious propensity is too obvious to entitle him to any regard.
[13] See the quotations in Lipsius, *Concil. Turonens,* ii. 15; Lactant., *Div. Just.* i. 4; Aug., *de Civ. Dei,* vi. 10; Tertull., *de Anim.* i.; Jerome, *de Script. Eccl.* c. 12.

sopher; but he acted on the principle that, as far as he himself was concerned, he might dispense with the laws of morality which he laid down for others, and that he might give way to his natural propensities."[1] This judgment may sound harsh, but in point of fact Seneca never professes for a moment to rise in practice to the level of his philosophic aspirations. He was, he tells us, not virtuous, but a lover of virtue; not a philosopher, but a student of philosophy. "I am pre-occupied," he says, "with vices.[2] All I require of myself is, not to be equal to the best, but only to be better than the bad."

As a philosopher, Seneca has no great claims on our attention. He abounds, indeed, in those noble and advanced ethical conclusions whose wide dissemination made them the *avant-couriers*[3] for the reception of Christianity, and which seem to have resulted from the profound thoughtfulness forced upon the greatest intellects by the desperate condition of the times. But we find in him no approach to a consistent system; he expresses the thoughts of the moment with eloquence and precision, but perhaps in the next treatise we find him contradicting and refuting them. His intellect[4] has an encyclopædic character, and like some modern writers, he united the claims of orator, poet, philosopher, geographer, historian, and naturalist. In all these branches of learning he shows conspicuous cleverness, but does not rise in any of them to first-rate eminence. Caligula was not far wrong in criticising his intellectual efforts as "commissiones meras," isolated and unsubstantiated displays. Seneca had successively experienced the weariness of exile, the luxury of power, and the bitterness of retirement and disgrace, and it is no wonder that his works contain many inconsistencies, because they are strongly marked by the impress of the period of his life at which they were written. For instance, in his book *De Constantiâ Sapientis*, glowing in all the fervour of philosophic intolerance, he eloquently praises the quietism and ἀπαθέια of Stilpo; whereas in the *De Animi tranquillitate*, and in the *De Otio Sapientis*, published after his recall from exile, he departs widely from the principles of stoicism, and pronounces with equal enthusiasm in favour of an active life.[5] The treatise, *De Vita Beatâ*, composed at a later period of his court career, becomes almost Epicurean in its estimate of worldly advantages, and in some places sounds like a personal apology for those actions of Seneca which were most open to adverse criticisms. In a similar manner we can trace in the wavering and often contradictory conclusions of his other writings the immediate influences by which he was surrounded.

Besides the works which we have mentioned, Seneca wrote excellent little treatises on Providence and on the Shortness of Life; three books on Anger, which, according to Valerius Maximus, was a prevalent vice of the Roman character; a Dissertation on Clemency, addressed to Nero at the commencement of his reign; and seven books on Benefits, in which he takes care to prove that, in spite of the boundless gifts which Nero had heaped upon him, the favours of a tyrant are wanting in all the requisites which invite or necessitate a feeling of gratitude. But his two best works are the *Letters to Lucilius* and the *Natural Questions*. In the *Letters*, written during his old age and retirement, he stores up the mellow maxims of a long and chequered experience; laying aside the pedantry of the philosopher, he gives free and natural expression to the hopes and emotions of the man. Foreseeing the ultimate necessity of suicide, he looks forward to it with calm and steady pleasure, as a happy release from the insolence of power and the plots of crime. The seven books of *Naturales Quæstiones* were commenced during his exile, but finished and revised in his later years. They contain many fine passages and curious conjectures. But Seneca studies physical science only for the sake of its moral applications. If he speaks of the composition of mirrors, he takes occasion to denounce the abuse of them for the purposes of vanity and vice; if he is treating of poisons he bursts into an eloquent digression against the refinements of Roman sensuality. The main object of his work is to remove superstitious errors and empty fears, and his work may be regarded as a religious continuation of the atheistic speculations of Lucretius.[6]

Whether the wretched epigrams attributed to Seneca are genuine is uncertain; that the ten tragedies which pass under his name are so is generally admitted, and could perhaps never have been doubted but for the distinction which Sidonius Apollinaris makes between Seneca the tragedian and Seneca the philosopher. The isolated testimony of such an author cannot outweigh the evidence of Quinctilian,[7] and other writers who were almost Seneca's cotemporaries. These tragedies are adapted not so much for the stage as for recitation, and are not to be compared with the great dramas of the Greek poets; but they contain many beauties, and do not at all detract from our high estimate of Seneca's literary abilities.

It has been said that the man who corrupts the style of his age is often as great a genius as the man who improves it. Seneca is a case in point, for to him was mainly due the inferior taste of the later Romans. The desire to say brilliant things—the antitheses and ornaments of his language—in a word, his conceits of rhetoric would, as Niebuhr has remarked, be quite intolerable if they came from a less ingenious man. Quinctilian, who was accused of depreciating him, happily observes that "he abounds in beautiful defects, and that one could have wished him to follow his own genius, and some one else's judgment."[8] Inferior writers imitated his *dulcia vitia*, without the ability which rendered them endurable; and adopted his picturesque turns of expression, without the thoughtfulness which made them valuable. He has been the special favourite of French writers; and Montaigne and Diderot have spoken warmly in his praise. He was the undoubted source of a great intellectual movement; and we may trace his influence, not only in writers like Florus and Quintus Curtius, but in Pliny, Quinctilian, and even Tacitus himself. "Tacite," says Montaigne, "ne tire pas mal à l'escrire de Sénèque;" and although the historian seems to have regarded the philosopher with a little spleen, yet he was, perhaps, indebted to him unconsciously, not only for isolated thought, but for the very idea of his historical style.

Among the editions of Seneca we may mention that of Schottus, Paris, 1607; and the Bipont edition, Strasbourg, 1809. There is a French translation by Lagrange, and an English one by Dr Thos. Lodge, Lond., 1614. (F. W. F.)

SENEGAL, a river of Western Africa, formed by the union of two branches, called the Ba Fing and the Ba Woolima. The former, which is the larger of the two, rises about N. Lat. 10. 30.; W. Long. 11. 19., in the mountains forming the south border of the elevated plain of Foota Jallon. It flows first to the east, past the town of Timbo, then turns to the north, traversing the desert of Jallon Kadoo; and after a course of more than 400 miles, unites its waters with the Ba Woolima. This river rises considerably to the N.E. of the other, near the left bank of the Joliba, or Niger, about N. Lat. 13., and W. Long. 7. 50. It flows first N.W., then W. for a distance of 300 miles, before joining the Ba Fing. The confluence takes place

Senegal.

about N. Lat. 14. 10., W. Long. 10. 30. From this point the united stream runs first N.W., and then W., till it falls into the Atlantic, by two mouths, near the French settlement of St Louis. The whole length of the river is estimated at 1000 miles. Its most important affluents are the Furkooma, which joins the Ba-Fing; the Kokorro, which flows into the Ba-Woolima; and the Ba-Faleme, which falls into the united stream. In the lower part of its course the Senegal several times divides itself into branches, which enclose islands of considerable size. The navigation of the river is interrupted by the cataract of Feloo, which is 80 feet high, and nearly 600 miles above the mouth of the river, following its course, though not more than 350 in a straight line. This cataract, which is situated about 100 miles above the confluence of the Ba-Faleme, is the principal one on the river; forty miles above it is that of Govinea. The windings of the Senegal are remarkably tortuous and circuitous. As far as the rock of Feloo, the country through which it flows is a level, having so small an inclination that a very slight interruption is sufficient to divert the course of the stream, so that it frequently seems on the point of returning to its source. It is only navigable during the rainy season, which extends from June till November; and even then the navigation is very slow and tedious. At the mouth of the river there is a bar, which prevents the entrance of all vessels drawing more than 12 feet of water, although immediately within it there is sufficient depth for ships of any size. The entrance of the bar has shifted from time to time, owing to the influence of opposite currents. Were it not for the perils to be met with on this river, it would be particularly interesting to the naturalist, as the extremely picturesque banks present a rich variety of the noblest productions of the vegetable kingdom, whilst the extensive forests abound with all kinds of wild animals. Amongst others, elephants are seen in large troops. In the shallow parts of the river are a vast number of hippopotami, and caymans of prodigious size. The Senegal, like the Nile, annually overflows its banks, and spreads its fertilizing waters over the surrounding country. It forms the boundary during a great part of its course between the arid plains of the Sahara on the north, and the fertile regions of Senegambia on the south.

SENEGAL, a colonial dependency of France, on the W. coast of Africa. It consists of the island and town of St Louis, at the mouth of the Senegal; several forts along that river; the island and fort of Gorée, off Cape Verd; and Allreda, at the mouth of the Gambia (see LOUIS ST, and GOREE). The trade and navigation of these settlements is considerable. In the year 1852 there entered at St Louis 89 vessels, all French, with a tonnage of 11,451; and there cleared 69, likewise all French, with a tonnage of 7418. At Goree in the same year there entered 330, of which 309, tonnage 19,503, were French; and there cleared 280, of which 262, tonnage 16,345, were French. The following table exhibits the amount of goods of different kinds exported to France in 1855:—

St Louis.			Goree.	
Articles.	Cwt.	L.	Articles.	Cwt.
Hides	3,069	11,247	Hides	4,130
Arachis & other nuts	80,298	122,616	Yellow & brown wax	2,151
			Ivory	22
Pure gum	44,237	126,094	Arachis and other nuts	83,192
Palm oil	205	...	Caoutchouc and Gutta percha	1,181
Dye Woods	7,074	...		

The value of the whole exports from St Louis was L.283,972; and from Gorée, L.297,638. The trade seems to be gradually but steadily passing from St Louis to Gorée. The population of the settlements in 1855 was as follows:—

	Inhabitants.
St Louis	9,223
Güet-N'dar	1,796
Forts on the Senegal, viz:—Bakel, Sénoudebou, Dagana, Richard Toll, Mérinaghem, and Lampsar	4,818
Gorée (1856)	2,633
Total	18,470

Senegambia.

SENEGAMBIA, a country of western Africa, comprising, as its name implies, the regions watered by the Senegal and the Gambia. It lies between N. Lat. 10. and 17., W. Long. 8. and 17. 30.; bounded on the N. by the Sahara, E. by the Soodan or Nigritia; S. by Sierra-Leone, and W. by the Atlantic; area, about 381,500 square miles.

Boundaries and coast. Except a short distance on the southern side, the country is entirely encircled with natural limits. On the W. lies the ocean; on the N. the course of the Senegal forms a clear line of demarcation between the Sahara and Senegambia; on the E. and S.E., the mountains which divide the Senegal and Gambia from the valley of the Niger separate it from Soodan; and there is only an arbitrary line from the source of the Rio-Grande to Cape Verga, which forms the southern limit of Senegambia, and the northern of Sierra-Leone. The coast line extends from the mouth of the Senegal to Cape Roxo nearly due S., with the exception of the peninsula of Cape Verd, which stretches to the W., forming the extreme point of Africa in that direction. At Cape Roxo the direction of the coast changes to S.E., which continues till beyond the limits of Senegambia. Beside those already mentioned, the only considerable promontory along the shore is Cape St Marie, forming the S. side of the estuary of the Gambia. There are no arms of the sea running into the land, nor any indentations, except the mouths of the Senegal, Gambia, Rio-Grande, and Nuñez. The only islands along the coast are those of Senegal, Gorée, and the numerous group of the Bissão Islands. The coast of the northern part of Senegambia resembles very much that of the Sahara, of which it is a continuation. It is almost entirely low, barren, and monotonous, bordered with ridges of sandy dunes, and only interrupted in a few places by rocky cliffs and plateaus. Towards the S. of the country the appearance of the coast is somewhat different, on account of the many small rivers which enter the sea, forming islands and deltas; and bringing down a quantity of rich alluvial soil, on which a luxuriant vegetation flourishes; baobabs, mangroves, and palms growing close to the edges of the rivers and the ocean.

Surface, mountains, and rivers. From the coast there stretches inland a vast level expanse, occupying more than the half of Senegambia. This plain is about 150 miles at the S., and widens towards the N. to a breadth of 200 miles. East of this lies a mountainous region, which occupies all the rest of the country. Though not very lofty, these mountains are extensive and intricate, sending off many branches and offshoots from the principal mass. To the E. they descend steeply to the valley of the Niger; towards the south they stretch continuously into Sierra-Leone and the interior of Guinea; towards the W. they descend by a series of terraces to the plain of Senegambia; and towards the N. they extend across the Senegal for a short distance into the Sahara. In this mountainous region there are many plateaus and valleys stretching generally from S. to N., through which the rivers of the country take their course. No accurate measurements have been taken of any of the summits in Senegambia, but the N.E. portion, which is the loftiest, as well as the wildest, most impervious, and inhospitable, is not probably more than 6000 feet above the sea; while the general elevation of the table-land varies from 1200 to 1500 feet. The declivity towards the W. is steepest near the S. of the country, where the summit of Mount Sangari, not far removed from the plain, attains an elevation of be-

tween 5000 and 6000 feet. The plateau of Senegambia is in many respects analogous to that of Abyssinia, near the opposite extremity of Africa. These two regions resemble each other in the character of their mountains, the terraces by which they descend to the low ground, and the nature and productions of the soil; and they seem like two bastions at the extremities of the long level tract of Soodan. The chief rivers of Senegambia are the Senegal, Gambia, Rio-Grande, and Nuñez; all of which rise among the mountains, and fall into the Atlantic.

Geology and soil. The geological structure of the country has not yet been thoroughly investigated, especially towards the interior. The flat region along the coast is very uniform in its character. It consists of masses of sand and clay, along with a loose red soil, containing in some places numerous sea-mussels. In some places, as at Cape Verd and Cape Roxo, masses of sandstone occur; those at the latter place, by their red colour, have given the name to the promontory. Clay-slate is also met with; and here and there these Neptunian formations are interrupted by basaltic, amygdaloid, and volcanic rocks. Thus the island of Gorée consists of basalt; the Bissão Islands, of scoriæ and other volcanic substances; and a large part of the coast north of the Nuñez, of basalt and amygdaloid. The foundation of the mountains consists in some places of clay-slate, but more commonly of granite, porphyry, syenite, and trachyte. Mica slate and ironstone are also found in these regions. Excellent iron, as well as considerable quantities of gold, are obtained among the mountains. Many of the valleys in this region have a fertile soil, and so has the land along the banks of the Gambia and along the shore to the S. of that river; but in the rest of Senegambia the soil is of great sterility.

Climate. The climate is one of the hottest on the surface of the earth, and the sun's heat is so intense as to be dreaded even by the natives. On the Senegal, where for eight months in the year hot dry winds blow from the E. over the whole length of the burning soil of the Sahara, the thermometer at 6 o'clock A.M. stands at 82° or 84°; and at mid-day even in the shade rises above 89°. In the valley of the Gambia, too, the heat is exceedingly oppressive, at some places in May the thermometer stands the whole day at 104°. Even in the hilly country, as high degrees of temperature are not seldom experienced. The atmosphere, on the whole, is extremely unhealthy, especially for Europeans; some districts, and some times of the year, are more favourable than others, but these are merely degrees of insalubrity. There are two seasons, a dry and a rainy one. In the former, which lasts from November to June, the air is clear; and the lakes and standing water are dried up. The rainy season is introduced by tremendous thunderstorms; the rivers overflow the flat land, and form extensive marshes; the wind generally blows from the W. or N.W.; and all kinds of vegetation spring up with the utmost luxuriance. This season is the more unhealthy, and during its continuance a dangerous marsh fever prevails.

Vegetables. The vegetable productions of Senegambia resemble those of the other parts, especially the tropical parts of West Africa, and are not very remarkable for the variety of their forms. For a considerable distance from the sea-shore the vegetation, except along the banks of the rivers, consists entirely of long grasses, which grow up during the wet season, and when dried up are burned by the natives, so as to leave the ground entirely bare, with only here and there a few mimosa groves. On the ground inundated by the rivers, however, there grow mangroves, acacias, mimosas, oil-palms, and the gigantic baobab, or monkey bread-tree, which, though not very high, has sometimes a circumference of 77 feet. The whole flora of the maritime plain of Senegambia has a considerable resemblance to that of the E. coast of Africa, especially of Abyssinia. The productions of the interior are not so well known as those of the coast. Dense forests begin near the foot of the mountains, and clothe their acclivities up to a certain height. Above this limit grow the ceiba-palm, and the shea or butter-tree, which furnishes here, as in the neighbouring countries, an important article of food. The extent of cultivation throughout the country depends much more on the degree of civilization of the people than on the capabilities of the soil. In some places, especially near the villages of the Mandingos, there are tracts of land very well cultivated; in others, very little attention is paid to agriculture. Besides rice, maize, and other grains, cotton, indigo, tobacco, sugar-canes, manioc, yams, pistachio and arachis nuts are raised.

Animals. The animals of Senegambia also resemble, to a considerable extent, those of Eastern Africa. It abounds especially in monkeys and elephants. Large herds of the latter range the forests on the Senegal. Beasts of prey of various kinds, especially lions, panthers, and hyænas are also found; as well as antelopes, buffaloes, boars, and hippopotamuses. Fish and alligators abound in the rivers; and turtles and oysters on the sea-coast. Of domestic animals, there are horses, small, but swift and spirited; asses; horned cattle; sheep; and goats; besides a number of camels in the regions near the Sahara.

Inhabitants. Senegambia is, on the whole, well peopled, especially in the mountainous region; for the plains for the most part admit only of a migratory population. The inhabitants are divided into a great number of small tribes, differing in many cases very remarkably in their physical appearance, language, and character. With reference to these characteristics, the multitude of small states may be reduced to a few great groups; the most important of which are these three—the Jolofs, Mandingos, and Foolahs. The Jolofs once formed a powerful kingdom in the plain between the Senegal and the Gambia, and they still occupy that country, though they are divided into a number of petty states. Their bodies are strong and well proportioned; and their features regular and handsome, approaching those of Europeans. Their hair, however, is crisp and woolly; and their colour is the deepest black of any race, resembling polished ebony. They speak a language that agrees with that of the Kaffres in some peculiarities hardly found in any other tongue. In character, they are energetic and warlike. The Mandingos originally came from the mountainous district of Manding, in the extreme S.E. of Senegambia, where they are still settled; but they have spread by conquest and migration down the southern terraces of the mountains to the coast near the mouth of the Gambia. Their features have more of the negro cast, but their complexion is a shade lighter than that of the Jolofs. They are very industrious, especially the Mohammedan branches of the people, and exhibit a good deal of intelligence. The Mandingos are supposed to be the most numerous of all the races that inhabit Senegambia. The Foolahs originally occupied the small country called Foolah-du in the N.E. of Senegambia, but from that region they have spread themselves far and wide in all directions. Within Senegambia they have occupied the kingdom of Timbo in the S.E., and that of Foota-Toro in the low land, on the Senegal; and in Soodan, under the name of Fellatas, they have acquired extensive dominions. Their features and complexion approach very closely to the European type; their hair is long and silky; and in intellectual and moral character they are much superior to the other African races. They are divided into various nations of different degrees of civilization. There are various other tribes in Senegambia of less size and importance; such are the Serracolets, who carry on the trade with the French along the Senegal; the Sereres, near Cape Verd; the Jolas in the south; and many others.

Religion and government.

The religion of the Senegambians is partly heathenism and partly Mohammedanism. Christianity has made progress among the natives only at a few places along the coast. Heathenism appears under the form of fetish worship, but is not accompanied here with such bloody rites as are common in many parts of Guinea. Mohammedanism has made progress chiefly among the Mandingo and Foolah tribes; much less among the Jolofs, and hardly at all in the smaller nations. For a series of years it has made great advances in Senegambia, through the zeal of the marabouts or priests, and the erection of schools for teaching the Koran. The natives who have embraced the religion of Mahomet are favourably distinguished above the heathen tribes for industry, intelligence, hospitality, and clemency. The form of government varies considerably in the different states of the country. Among the Foolahs it is generally a despotic monarchy, the sovereign being at the same time the chief priest of the community; while in the other states the monarch is generally limited in power by the nobles or chieftains; and in some the government approaches the aristocratic, or even the democratic form. Among many of the tribes which are less civilized hardly any bond of union subsists beyond what is necessary for self-defence.

Divisions.

The names of the principal states of Senegambia are as follows:—Belonging to the Jolofs—Wallo, at the mouth of the Senegal; south of it, Cayor; further south, Baol; still further, Sin; and Jolof, east of the last two. Belonging to the Mandingos—Bambuk, between the Senegal and Ba-Faleme; Dentilia, between the latter and the Gambia; Tenda, to the west of the foregoing, along the Gambia; Wulli, north-west of Tenda; Yani, further west, on the north of the Gambia; Salum, still further west; and Barra, between Sin and the Gambia. Besides these, which all lie contiguous to each other, there are two isolated Mandingo states—Manding in the extreme east, and Kaarta north of the Senegal. Belonging to the Foolahs—Foota-Toro, south of the Senegal, near its mouth; Bondu, south of that; Kasson, north of the Senegal; Ludamar, still further north; Foolahdu between the upper branches of that river; and Foota-Jallon, south of the Mandingo tribes. Other native tribes—Galam or Kajaaga, Jallon-Kadu, the country of the Felups, of the Papels, &c. The European settlements in Senegambia belong to the British, the French, and the Portuguese. The British settlements are in the middle of the coast, about the Gambia (see GAMBIA); the French north of them, chiefly on the Senegal (see SENEGAL); and the Portuguese south of the British, comprising the Bissão Islands, and some stations near the Rio-Grande. Some commerce is carried on between Senegambia and the countries of Soodan. Salt, slaves, and gold are the principal articles of merchandise. The total population of the country is estimated at nine millions.

SENESCHAL (*Seneschallus*), derived from the German *sein*, "a house or place," and *scale*, "an officer," is a steward, and signifies one who has the dispensing of justice, as the high seneschal or steward of England; *seneschal de la hôtel de roi*, "steward of the king's household" (*Co. Lit.* 61; Croke's *Jurisd.* 102; Kitch. 83).

SENLIS, a town of France, capital of an arrondissement in the department of Oise, on the slope of a hill, 29 miles S.E. of Beauvais. It consists of an old town and three suburbs; and has narrow, crooked streets, lined with well-built houses. There are here an old castle, a small but stately cathedral, chiefly of the twelfth century, and some churches now used for other purposes. The manufactories consist of cotton mills, tanneries, printing-houses, &c. Many traces of Roman structures have been found here. Pop. (1856) 5172.

SENNA, the leaves of several species of *Cassia*, as *acutifolia*, *lanceolata*, *elongata*, and *obovata*, is a useful purgative, and was imported from Egypt, the British East Indies, the Hanse Towns, and elsewhere, in 1857, to the amount of 219,191 lb., at a total value of L.4730.

SENNAAR, a country of Eastern Africa, formerly an independent kingdom, but now a part of the Ottoman empire, belonging to the province generally known to Europeans under the name of Nubia, called by the Turks the pashalic of Sennaar, and by the Egyptians, Beled-es-Soodan, or the Land of the Blacks. Its limits are not very accurately defined; but it extends along the banks of the White and Blue Nile as far north as the confluence of these two rivers at Khartoom, and is bounded on the north by Dar Shendy, E. and S.E. by Abyssinia, S. by the country of the Nuba mountaineers, and W. by Kordofan. It lies between 12. and 15. 45. N. Lat.; has a length of about 260 miles, a breadth of nearly the same; and an area estimated at 60,000 square miles. The greater part of the country lies between the White (Bahr-el-Abiad) and the Blue Nile (Bahr-el-Azrek), but some part of it also lies to the east of the latter, between it and the Atbara, the largest of the affluents of the Nile. The surface consists of an almost unbroken plain, extending from the Atbara across the Blue and the White Nile to the borders of Kordofan. Its general elevation is from 1400 to above 1500 feet above the level of the sea; Khartoom being 1431, and Sennaar 1515 feet high. The country has thus a slight slope towards the north. Its uniformity of surface is only interrupted by a few isolated mountains, rising from 800 to 900 feet above the surrounding country. Such are Jebel, Szegeti, and Moje, to the west of the town of Sennaar, and Mandera to the east of the same place; which rise like rocky islands in the midst of the sea-like expanse of the country. The southern limit of the plain of Sennaar occurs about the latitude of Seru, on the Blue Nile, about 50 miles in a direct line above Sennaar. Beyond this rise the mountains in the districts of Roserres and Fassokl, which are offshoots of those of Abyssinia to the east. The chief summits are Fassokl (2659 feet), Kassan (3024 feet), and Akaro (3094 feet). Notwithstanding the level character of the land through which they flow, both the streams of the Nile have here a considerable fall; that of the Blue River from Roserres to Sennaar being 0·14 feet per mile, from Sennaar to Wood Medineh, 0·33 feet, and from Wood Medineh to Khartoom 0·53 feet; while that of the White Nile is still greater, being 0·87 feet between Eleis and Khartoom. The uniform character of the plain of Sennaar must be ascribed in a great degree to its geological formation. It consists, like the land of Egypt, almost entirely of regular horizontal strata of sandstone. The mountains, however, are of a totally different structure. They consist exclusively of crystalline rocks, mingled with grauwacke, clay-slate, and limestone. Most of the isolated hills in Sennaar are composed of granite; those in the districts of Roserres and Fassokl, on the other hand, consist of chlorite-slate, with veins of auriferous quartz; and the most of the mountains between the Blue Nile and its affluent the Tumat, of gneiss. Besides gold, iron is found among these mountains, and also in the desert between Sennaar and Kordofan. Salt is obtained at Khartoom, and along the White Nile; and the granite of Mount Szegeti is very excellent, being superior to that of Syene. With these exceptions there are no important minerals in the country. The soil is very fertile, especially in the region east of the Blue Nile. Along the banks of both branches of the river extend dense forests, especially of doom and date palms, baobab trees, and, in the upper parts of the river, of tamarinds. The flats between the two rivers are generally bare and parched during the dry season. After the rains they are either changed into vast grassy savannahs; or else acquire the character of muddy tracts, on which the natives

sow the dhurra seed. This grows up in a few months, and gives the country the aspect of one great corn-field; it is then cut down, and the ground reassumes its sterile appearance. This primitive mode of husbandry is the most common in Sennaar; but there are also other crops raised, such as wheat, sugar-canes in a few places, cotton, tobacco, and, of late years, indigo. The climate is excessively hot; the mean annual temperature being from 80° to 82°. In spring the temperature at noon is frequently above 100°, and in summer it attains a still greater height. This excessive heat produces opposite effects on the country, according to the nature of the soil; in some parts parching it up into an arid desert, and in others fostering a most luxuriant vegetation. The seasons are two in number, and very well defined, a dry and a rainy one. The latter lasts for four or five months in the summer, and is ushered in by tremendous hurricanes; the former continues for the rest of the year. The first indications of the annual inundation of the Nile take place in May; during June it is steadily rising; and attains its greatest height in September. The hilly parts of the country enjoy a salubrious atmosphere; but in the low, flat regions the climate is very unhealthy. Among the wild animals of Sennaar may be numbered the elephant, the rhinoceros, and the hippopotamus. In the dense forests many species of monkeys are found, beasts of prey, such as lions, leopards, hyænas, and wild-cats are numerous, as well as thousands of antelopes in the savannahs of the Blue Nile; giraffes, buffaloes, and goats are also found. Crocodiles abound in the rivers, and many kinds of serpents infest the country. Among birds the most important is the ostrich, which inhabits the desert between Sennaar and Kordofan, and whose feathers are an important article of commerce. Of domesticated animals, horses are more numerous here than in the lower valley of the Nile, while the large herds of camels and horned cattle, and the flocks of sheep, form the chief wealth of the wandering tribes in the uncultivated regions. The origin of the people of Sennaar is involved in much obscurity and doubt. Their bodies are well built, and their colour is a dark copper brown. They have long and curly, but not woolly hair; and their features are quite different from those of the negro. There are many different classes of people, somewhat differing in their characteristics from each other; some more nearly approaching to the Arab, and some to the negro type. The prevailing religion in Sennaar, as in the whole of Nubia, is the Mohammedan, except in the extreme south-east, where there are many Christians and heathens of Abyssinian origin. The kingdom of Sennaar was founded in the beginning of the sixteenth century, by a tribe of Shilluk negroes, who invaded and conquered the country; and called themselves by the name of Fungi or conquerors. For a long period this kingdom remained independent, under its own melik or king, until, in 1820, Mohammed Ali, pasha of Egypt, determined to reduce under his sway Sennaar and the adjacent countries, and undertook an expedition for that purpose. The result was the conquest of the country and its annexation to the Ottoman empire. The population of the province is estimated at a million and a half. The chief town is Sennaar, formerly the capital and residence of the monarch. It stands on the left bank of the Blue Nile, 1150 miles south of Cairo. It has extensive suburbs, about $3\frac{1}{2}$ miles in circuit. The town is ill built, consisting principally of low houses; and it contains several mosques and a ruined palace. There is some trade in basket-work, arms, and silver articles. The population has dwindled from upwards of 12,000 to 7000.

SENNERTUS, Daniel, called by some the German Galen, was an eminent physician, and was born at Breslau in 1572. In 1593 he was sent to Würtemberg, where he made great progress in philosophy and in physic. He visited the universities of Leipsic, Jena, Frankfort-on-the-Oder, and Berlin; but he soon returned to Würtemberg, where he was promoted to the degree of doctor of physic, and soon afterwards to a professorship in the same faculty. He was the first who introduced the study of chemistry into that university, and he gained a great reputation by his works and practice. He died of the plague at Würtemberg in 1637. He sought to reconcile the doctrines of Paracelsus with those of Galen, and seems, in all respects, to have been in advance of his age. He thought the seed of all living creatures animated, and that the soul of this seed produced organization. He was accused of impiety for asserting that the souls of beasts are not material, for this was affirmed to be the same thing with asserting that they are immortal; but he rejected this consequence, as well he might. The writings of Sennertus, a number of which were translated into English, were published in folio at Venice in 1645, and subsequently at Lyon and at Paris.

SENS, a town of France, capital of an arrondissement in the department of Yonne, near the right bank of the Yonne, 70 miles S.E. of Paris. It is partially encircled by old walls, and entered by nine gates, three of which are of mediæval origin. Though a small town, it is neat and well built, with broad straight streets, which are kept clean by small brooks of water from the Vanne, an affluent of the Yonne. The principal building is the cathedral, a very magnificent specimen of the early Gothic style, remarkable for its tracery and painted glass. It contains the canonical vestments of Thomas à Becket, probably genuine, as he fled hither from the anger of Henry II. The town has also an ecclesiastical seminary, hospital, theatre, public baths, and promenades. There are a large public library, a college with a museum, and courts of law. Leather, cotton, yarn, straw-hats, woollen fabrics, hardware, candles, tiles, earthenware, &c., are manufactured here; and there is a considerable trade in corn, flour, wine, wool, hemp, timber, and manufactured articles. Sens occupies the site of the ancient Agendicum, and derived its modern name from the Senones, in whose territory it stood. Under the Romans it was the chief town of Lugdumensis Quarta, and the meeting-place of several roads. Some sculptured stones, of Roman workmanship, have been built into the walls of the town. Pop. (1856) 9869.

SENSATIONALISM, or Sensualism, is a term employed to designate those systems of philosophy which either directly or indirectly deduce all our knowledge from sensation, or from the experience which sense affords. Such, for example, are the sensational philosophers of the eighteenth century.

SEPOURY, or Sipery, a town and fortress of Hindustan, province of Agra and district of Gohud, taken by the British in 1781. It is 18 miles S.W. of Narwa.

SEPOYS. See Hindustan.

SEPTEMBER, the ninth month of the year, consisting of thirty days. It took its name as being the seventh month from March, with which the Romans began their year. Since 1752 our legal year has commenced in January.

SEPTUAGESIMA, in the calender, denotes the third Sunday before Lent, or before Quadragesima Sunday. It is supposed by some to take its name from its being about seventy days before Easter.

SEPTUAGINT, a Greek version of the Old Testament, which received this name either from the supposition that it was the work of LXX. or LXXII. translators, or more probably because it received the sanction of the Jewish Sanhedrim, which consisted of that number of members. If the latter reason be correct, the title is exactly equivalent to our Bishop's Bible, so called because it was a translation recommended by the authority of the English bishops.

Archbishop Usher places the date of this version B.C.

Septuagint. 277, following the story of its origin, which was so long current under the name of Aristeas, who professes to have been an officer of Ptolemy's guard at the time when the transaction took place. The story is as follows. Ptolemy Philadelphus having heard of the Jewish law from Demetrius Phaleteus, to whom he had entrusted the care of his Alexandrian library, ordered that a copy of it should be sent for, and that it should be rendered into Greek by properly qualified interpreters from Jerusalem. Aristeas and two other nobles took this opportunity to urge on the king the liberation of the Jews who had been taken captive by Ptolemy Soter, saying that unless this was done, obstacles would be put in the way of his wish. Accordingly, at the enormous expense of 660 talents, he procured the freedom of 198,000 Jewish captives, and then, by the advice of Demetrius, wrote to the high-priest Eleazer asking for a Hebrew copy of the law, and seventy-two translators (six out of each tribe), competent to render it into Greek. Aristeas was one of the bearers of this letter and of the splendid gifts which accompanied it, and he returned to Egypt with the translators, and a copy of the law written in golden letters. On their arrival at court, the translators having proved their wisdom by impromptu answers to the seventy-two questions put to them, were conducted to the Pharos, and there by common conference completed their task in seventy-two days, whereupon the king dismissed them home with regal munificence.

Besides Aristeas, the Septuagint is mentioned by Aristobulus[1] (an Alexandrian Jew who wished to prove the foolish surmise that the Greeks had plagiarized their philosophy from Scripture); by Philo,[2] and by Josephus.[3] Philo adds the further particulars, that each translator rendered the *whole* book; that they were found at the conclusion to have agreed verbally with each other by the miraculous aid vouchsafed to them; and that a solemn anniversary was kept in honour of the occasion. Justin Martyr, following common rumour, still farther improves the story, and believed that he had actually seen the ruins of the seventy cells in which the distinct versions were miraculously made; and thus in one form or other this marvellous fiction received full credence among the ancient fathers—*e.g.*, Irenæus, Clemens Alexandrinus, Hilary, Augustine, and Cyril of Jerusalem. Epiphanius also repeats the story with variations and additions; and it was believed for centuries with the most unquestioning confidence. The obvious inference was, that the LXX. version, with all its errors and imperfections, must be regarded as inspired.

But it has now been demonstrated that the book of Aristeas is an idle forgery, a mere religious romance, written by a Hellenistic Jew to magnify his nation, and to exalt the credit of this Greek version. His whole narrative bears the stamp of Jewish exaggeration and self-complacency. The author, professing to be a heathen, uses throughout language which could only have emanated from a Jew. The questions he puts in the mouth of Ptolemy are absurdly incongruous; the sum which he makes him disburse in accomplishing his wish (amounting to some 2.000,000[4] sterling) in utterly incredible; the distinction of the twelve tribes is an historical improbability, and several of the other particulars alluded to by him are confusions, anachronisms, or Pharisaical inventions. In fact, it is now admitted that the pseudo-Aristeas furnishes ample materials for the refutation of his own fiction, and since the learned work of Dr Hody, *De Bibliorum Textibus originalibus*, we are not aware that any one has attempted to defend the genuineness of his treatise.

But the question remains, is there a single germ of truth amid this mass of fable? It is indeed difficult to arrive at any certainty, but internal evidence supplies us with some strong probabilities. For instance it is clear,

1. That the version was the work of Alexandrian and not of Palestinian Jews. This appears at once from the freedom with which the Hebrew text is treated, since the Jews of Palestine would have been far more likely to adhere scrupulously to the most literal methods of rendering; a tendency which subsequently gave rise to the version of Aquila, which was called by them the *Hebraica veritas.* The language in which the LXX. is written is that Hellenistic Greek, that κοινὴ διάλεκτος which became so general after the time of Alexander the Great, and there are a number of expressions which could only have been used by a native of Alexandria. Thus, to take a few of the instances adduced by Hody,[5] the word shekel is in the pentateuch rendered by δίδραχμος; epha by Ὀιφι, which, it appears from Phavorinus, was an Egyptian measure; Zaphnath-Paaneah, the Hebrew name of Joseph, is turned into its Egyptian equivalent ψονθομφάνηχ; in Amos v. 26 the Egyptian Ῥεφὰν is substituted for the Hebrew Ciun; and in Job viii. 11 "reed" is rendered by "papyrus." A still more curious and decisive instance of this is the fact, that Thummim, the jewelled ornament of the high-priest's robe, is translated Ἀλήθεια or "truth," though the Hebrew word means "perfection;" we should be at a loss to account for this but for the information found in Ælian,[6] that the senior priest of the Egyptian hierarchy wore round his neck, while performing his judicial functions, an ornament of sapphires called by this very name "Truth." Besides all this, the translators, in the Apocryphal additions to the book of Esther, makes express mention of Ptolemy Philometor and Cleopatra; and when we add, that the universal tradition of the Jews themselves agrees in the main with these inferences (although Aristeas says that the translators came from Palestine), we may regard the Alexandrian origin of the version as sufficiently established.

But did the impulse which originated it come from within or from without? Alexander had transplanted a vast multitude of Jews to his new city, and had there given many privileges. Finding Alexandria a desirable place of residence, and being forced to speak the Greek language, which was at that time the common medium of communication, they gradually forgot the Chaldee, as, during the Babylonish captivity, they had forgotten the Hebrew. The Chaldee interpretation of the Scriptures used in their synagogues was, therefore, as obsolete to them as the original tongue, and they would doubtless feel the want of religious teaching in a language which they could comprehend. A literary motive may well have been combined with this religious motive, and it is by no means impossible that the general desire on the subject may have owed its first accomplishment to the additional influence of a king of Egypt, who wished so curious a record as the Pentateuch to be treasured up in the Alexandrian Library. In favour of this supposition is the annual festival, at which, according to Philo, the event is commemorated. The pseudo-Aristeas attributes the design to Ptolemy Philadelphus, and he has been generally followed; but the common Jewish account referred it to his father Ptolemy Lagus, and Hody reconciles the discrepancy by supposing the work to have been commenced during the years B.C. 286–285, when father and son were associated on the throne. Ptolemy Lagus, although kind to the Jews, was yet unpopular among them, because he had carried so many of them into captivity; and this may account for the omission of his name in the fable of Aristeas. It is probable that the Pentateuch alone was first translated, both from the distinct assertions by ancient writers to this effect, and from internal evidence;

Septuagint.

but in any case the manuscript, if procured for the Alexandrian Library, remained totally unknown, since nothing is more certain than the complete ignorance respecting Jewish history and institutions displayed not only by earlier authors, but even by the polished writers of the Roman empire.

2. The reasonings by which Hody and others attempt to arrive at a conclusion respecting the date of other portions of the Septuagint are very uncertain. For instance, it is argued from the use of the word γαισός in Joshua (viii. 18), that this book could not have been rendered until the employment of Gallic mercenaries by the Egyptian kings, *i. e.*, some twenty years after the death of Ptolemy Lagus, because γαισός means a peculiar kind of Gallic javelin.[1] But this argument is of very slender authority, nor can we deduce any strong inference from the mention of Ptolemy Philometor in the epilogue to Esther. It is, however, most probable, from a passage in the book[2] of the son of Sirach, that the whole had been completed before B.C. 130, in the reign of Ptolemy Physcon.

3. It is quite certain that it was made at different times and by different persons, although it is impossible to decide the exact number of translators employed on it. The common story speaks of 72; Epiphanius, of 36; the Jerusalem Talmud, of 5; and some of the Rabbis, of 3. Perhaps the real number was about 12 or 15. The different translators have adopted very different methods of rendering the same word, and even different modes of spelling the same common names; sometimes these names are made indeclinable, and sometimes a Greek termination is given to them. The rendering of Hebrew names for animals, trees, precious stones, weights and measures, are not only various but even irreconcileable. Thus, כְּפִיר, "a lion," is in Job iv. 10 rendered by δράκων; תְּאוֹ, "an oryx," is in Is. li. 20 represented by σευτλίον, a vegetable; and not to give any further specimens, תַּנִּין, "a whale," is rendered κῆτος, Gen. i. 21; "a dragon," Ps. lxxiv. 16, &c.; "a siren," Job. xx. 39; "a sparrow," Jer. x. 22; "a hedgehog," Is. xvi. 22; "a bird," Is. xxxv. 7; "a fig," Neh. ii. 13; and "affliction," Ps. xliii. 19! These instances are the first that came to hand out of ten pages[3] of similar ones in Hody's learned work; and some of these which he adduces prove that even the Pentateuch was not the work of a single hand. The Pentateuch is the part which was earliest and best executed; and of the books which it contains, Leviticus is translated best, and Numbers worst. The historical books are only tolerably rendered; the book of Proverbs admirably; the Prophets (especially Isaiah) indifferently. The vision of Daniel was so incomplete and erroneous, that Theodotion's version was substituted for it; it was long lost, and a manuscript of it was only rediscovered in 1772 in the Codex Chisianus at Rome. The translator of Job was a man of fine taste, profoundly read in the Greek poets, but a poor Hebrew scholar; this has led him into the awkward habit of omitting the passages which he did not understand.

From some curious agreements of the LXX. with the Samaritan Pentateuch, in some 2000 places, Hassencamp, and others have supposed that the translators made use of a Samaritan manuscript. But although there are those remarkable agreements, and although it has been thought that some variations in the LXX. may be accounted for by different readings, originating in the shape of the Samaritan letters, yet the numerous disagreements of the two tend to show that the points in which both differ from the Masorethic text are accounted for by the operation in both of false[4] principles of criticism; as, for instance, the desire to remove objections, to reconcile discrepancies, &c. And in some of these cases, where *both* have made an attempt of this kind (*e.g.*, Gen. v. 3-28; Ex. xii. 40), the method of the Samaritan is so much the more ingenious, that it is impossible to suppose that the Greek would not have adopted it had he been aware of it. There is, therefore, no necessity to assume great interpolation, numerous glosses, wilful corruptions, or any other of the numerous hypotheses which have been suggested to account for the numerous passages in which the Samaritan and the Greek agree, while both differ from the Hebrew. It is utterly incredible that Jews would ever have persuaded themselves to translate from a Samaritan text; and Abul Phatach's rival story of the origin of the Greek version of the Samaritan Pentateuch (which, according to him, was greatly preferred by Ptolemy Philadelphus), at least proves how unlikely it would have been for the Jews to use any other than the Masorethic text.

The importance of the Septuagint for all purposes of biblical criticism can hardly be overrated; and the influence which has been exercised by it for centuries renders the study of it imperative on every theologian. The fabulous accounts of its origin show the extravagant reputation in which it was held. Josephus used it in general; Philo, being ignorant of Hebrew, used it exclusively, and believed in its inspiration. Even in the Targums there are traces of a similar belief. Undertaken as it was without any suspicion of the controversies to which the interpretation of prophecy would subsequently give rise, and executed by men for the most part candid, zealous, and competent, it forms an invaluable commentary on the Hebrew text, and an historical specimen of the early method of exegesis. By rendering the Bible accessible to the learned of every country, it was an effectual safeguard against wilful interpolation, "so as to preclude all suspicion that it could be materially altered either by Jews or Christians, to support their respective opinions as to the person and character of the Messiah; the substance of the text being by this translation fixed and authenticated at least 270 years before the appearance of our[5] Lord." It was the version from which our blessed Saviour, in all probability, was taught to read when a child at Nazareth,—the version which he loved to quote, if not to the Pharisees and doctors of the law, at least to the common people, who heard him gladly, —the version which formed the text-book of apostolic teaching; from which all the ancient versions, except the Syriac, were made; which constituted the sole Scriptures of the Old Testament for the first four centuries; from which Augustine drew his meditations and Chrysostom his homilies. "The entire phraseology of the New Testament is formed on the peculiar style of the LXX,"[6] and any one who will consult Mr Grinfield's *Scholia Hellenictica*, may see at a glance that there is scarcely a page of the Gospels or Epistles which does not bear ample testimony to the fact, that the minds of the sacred writers were imbued with the style and language of this Greek version. It is well known that this Hellenistic Greek differs widely from the classical standard; and although it is a common error to attribute to Bentley the assertion that the dialect would have been altogether unintelligible to Demosthenes, yet certainly a Greek of the age of Pericles would have found it marvellously obscure. Hence the expressions of the LXX. are the ultimate source of our theological language, and "the Hebraic or Hellenistic Greek is the *sacred idiom.*" To it we owe such words as the ἀγάπη, ἁγιωσύνη, πνεῦμα, δικάιωσις, ἐυχαριστεῖν—the very keywords of the Christian

 religion. "There are many words," says Bishop Pearson, "which, from the mere usage of the Greek tongue, cannot be understood; which by collation with the Hebrews and the LXX. become easily intelligible. No one knows what σάρξ, what πνεῦμα signify among the Greek authors; and if you collect all the senses in which the Greeks use these words, you will find none that reach the apostle's meaning."[1] Thus, the dissemination of the LXX. paved the way for Christianity, and prepared the minds of men for the advent of an expected Saviour.

Direct quotations from the LXX. abound in the New Testament. In St Stephen's speech alone there are no less than twenty-eight, and the language of the Epistle to the Hebrews is "a kind of Mosaic, composed of bits and fragments of the LXX." Our Lord quoted it repeatedly. Out of the thirty-seven quotations made by him from the Old Testament, thirty-three are said to agree with the Greek[2] almost verbatim. It is certainly a striking and most important fact, that the apostles quote it and argue from it *even where it differs from the Hebrew;* "et quidem iis in locis," says Dr Mill on Heb. xiii. 25, "in quibus, si reponerentur Hebrea, non modo periret vis argumentationis Apostolicæ, sed *ne quidem ullus foret argumentationi locus.*" Instances of this may be found by the student in Luke iii. 37, Matt. xv. 8, 9, Acts ii. 25, Rom. x. 18, Heb. i. 7, ii. 7, x. 5, &c.

On these grounds it has been repeatedly argued, that, in order to maintain the doctrine of verbal or plenary inspiration, it is absolutely necessary to adopt the belief of the early Christian world as to the *inspiration* of the Greek translators. We have already seen that such a supposition prevailed among the Jews; it was the express belief of Irenæus, Clemens Alexandrinus, Hilary, and many of the fathers; it was strongly and frequently asserted by Augustine, and even his stout opponent St Jerome, whose study of the original Hebrew had given him a less favourable opinion, occasionally recurs to the old prejudice, and speaks of the Alexandrian interpreters as actuated by the extraordinary influences of the Holy Spirit. Even in modern times so strange an hallucination has not been totally dispelled; and Mr Grinfield's *Apology* supports the divine authority of the version with an earnestness and ingenuity which is deserving of a better cause.

For whatever inferences may be drawn from the fact, the dignity of truth demands the statement that the Septuagint abounds in errors, transpositions, interpolations, omissions, and defects of every kind, which abundantly prove that the translators were extremely fallible. Sometimes they show an imperfect acquaintance with Hebrew, sometimes with Greek, and sometimes they have made mistakes which can be attributed to carelessness alone. Nor are these variations due solely to defective knowledge; it is tolerably clear that they sometimes arise from a distinct purpose. Even the version of the Pentateuch is not free from this literary dishonesty. "It is obvious,"[3] says an able writer, "that the translator of Exodus had a plan which he strictly followed; and for the maintenance of his design he sacrificed the original text. Sometimes it was for a philosophical, sometimes for a political reason, at another time for the sake of saving the reputation for humanity of the Jewish legislator. Often he altogether neglected to translate words from which it might have appeared that the ordinances of the Jewish law were unnecessarily severe." Thus, in Ex. xiii. 13, he wilfully changes "thou shalt break his neck," into "thou shalt ransom it;" a rendering which is in direct contradiction to Lev. xxvii. 11. In Ex. xxiv. 10, 11, "they saw the God of heaven" is, from the Alexandrian pseudo-philosophical avoidance of anthropomorphism, absurdly rendered, "they saw *the place where* the God of Israel stood." In Ex. xv. 3, "the Lord is a man of war," is, for a similar reason, changed into "the Lord brings wars to nought;" and the same influence is at work in verse 10. Ex. xxxii. 9 is altogether *omitted* by this translator as unfavourable to the Jews; and he has given us a further indication of his political bias by the remarkable way in which he has softened the harsh expression of Ex. xxxii. 22. These instances, though taken from a single book, are chosen from a portion confessedly the best executed of the whole, and are no unfair specimens of the want of due regard to the text which sometimes misled them, even when their knowledge was not at fault. They are surely amply sufficient to prove, that to attribute inspiration to these Hellenists, is nothing else than an apotheosis of partial incompetence and positive mistake. In fact, the Septuagint translation must rather be regarded in the light of a paraphrase executed from the critical and religious[4] standpoint of Alexandrian Jews some two centuries before Christ. This will account for more inaccuracies and arbitrary alterations than any other principle; although besides this, it is possible that their manuscripts were often corrupt, and certain that they were without vowel points, final letters, or any of the other aids afforded by the later method of writing Hebrew. Nor must we overlook the enormous difficulty which had to be overcome in *creating* a style which should give in Greek a tolerable expression of Hebraic idioms and modes of thought.

The Jews first began to dislike and reject the Septuagint, when they found that its renderings were peculiarly valuable for the purposes of Christian controversy. They therefore adopted in lieu of it the version of Aquila, the chief merit of which is its slavish literalism. There seems, however, to be no adaquate proof that they instituted a stated fast on the 8th of Tebet, to execrate the anniversary of its completion, as we have no authority for this statement earlier than Justin Martyr.[5] Since the Septuagint had long been used in almost all their synagogues, this condemnation of it came a little too late in the day; and the Christians, who had no means of consulting the original, prized the translation with an extravagant veneration, and accepted it as an inspired production, and even preferred it to the Hebrew text. Jerome's profound learning led him to see that such views were untenable, and in forming the design of making a fresh translation from the Hebrew, he pointed out the necessity for doing so by showing the errors of the LXX. This proposal alarmed St Augustine as much as the suggestion of a revision of our English version alarms the more timid divines of the present day; and when Jerome was driven by the Bishop's opposition into further arguments, he finally forbade the use of Jerome's translation within his diocese. Ruffinus was even more violent and unreasonable in his attacks on the proposed innovation; and, on the whole, the Septuagint maintained its high authority until the conclusion of the eighteenth century, when it began to be rated at its true value, as a version which cannot be regarded as possessing any claims to equal authority with the Hebrew text, although it is exceedingly important for all the purposes of Scriptural interpretation.

When the Greek text began to accumulate a vast number of glosses, interpolations, marginal readings, alterations, and mistakes, Origen undertook his stupendous work, the *Hexapla*, in order to compare it with the Hebrew, and restore it, if possible, to its primitive condition. This noble undertaking, which might well entitle its author to the surname of "Adamantine," occupied (according to Epiphanius)

no less than twenty-eight years; but, in spite of its value, unfortunately increased the evil which it was intended to cure, since subsequent copyists often confounded and mixed together the various other texts which Origen had printed in parallel columns, side by side with the version of the LXX.[1]

The four chief editions of the LXX. are the Complutensian, the Aldine, the Sixtine, and the Grabian, which mainly follows the Codex Alexandrinus. A thorough revision of the text, and a good concordance, are still wanted: the lexicons of Biel and Schleusner are full of valuable information, but are still capable of very great improvement.

A vast number of books have been written on the Septuagint, and it only remains to enumerate the most important. Popular accounts may be found in Kitto's *Cyclopædia*, in Dr Davidson's *Bibl. Introduction*, in Horne's *Introduction*, vol. ii., and in Herzog's *Cyclopædia*, of which there is an English translation by Dr Bonberger. The classical book on the story of Aristeas is Hodius *De Bibl. Text. originalibus*, Oxon. 1705; and it is also examined in Gregory's *History of the LXX.*, Lond. 1664, and Van. Dale's *Dissert. super Aristeâ*, &c., Amst. 1705. An account of the disputes of Jerome and Augustin may be found in Du Pin's lives of these fathers. For further information see Pearson's *Prefatio Parænetica;* Walton's *Prolegomena*, c. ix.; Grabe's *Prolegomena;* Valcknaer, *De Aristobulo Judæo;* Thiersch, *De Pentat. Versione;* Toepler, *De Pent. Jut. Indole;* Studer, *De Vers. Alex. Origine*, &c. Important German books are, Dähne's *Judisch-Alexandr. Philosophie*, Halle, 1834, and Frankel's *Vorstudien*, Leipzig, 1841. The study of the LXX. is at present attracting much attention in England; and we have recently had valuable contributions to the literature of this subject by Mr Grinfield, Dean Howard, and Prof. Selwyn. (F. W. F.)

SEPULCHRE, Regular Canons of St, a religious order, formerly instituted at Jerusalem in honour of the holy sepulchre, or the tomb of Jesus Christ. Many of these canons were brought from the Holy Land into Europe, particularly into France, by Louis the Younger; into Poland, by Jaxa, a Polish gentleman; into Flanders, by the counts of that country; and many also came into England. This order was, however, suppressed by Pope Innocent VIII., who gave its revenues and effects to that of the Lady of Bethlehem; and this also becoming extinct, they were bestowed on the knights of St John of Jerusalem. These canons follow the rule of St Augustin.

Sepulchre, *Knights of the Holy*, a military order, established in Palestine about the year 1114. Those of this class chose Philip II., king of Spain, for their master, in 1558, and afterwards his son; but the grand-master of the order of Malta prevailed on him to resign; and when afterwards the Duke de Nevers assumed the same quality in France, the same grand-master, by his interest and credit, procured a like renunciation by him, and a confirmation of the union of this order to that of Malta.

SEPULVEDA, Juan Ginez de, a learned Spanish chronicler, was born at Pozoblanco, near Cordova, in 1490. He was educated first at Cordova, and afterwards at the university of Alcalá. Leaving the university in 1515, he set out for Italy, where he studied under the celebrated Pomponazzi, of Bologna. Having written the life of his patron, Cardinal Albornoz, he subsequently went to Rome and Naples, where he assisted Cardinal Caetano in revising the Greek text of the New Testament. He returned to Rome in 1529, and was appointed some years later chaplain and historiographer to Charles V. Leaving Italy, he now returned to his native country, and was induced to attack the celebrated bishop, Las Casas, who was then engaged in pleading the cause of the suffering Indians. But the royal council refused their imprimatur, and the world was deprived of this courtly book. Sepulveda wrote an *Apologia* in 1550; but this was unfortunately seized by order of the emperor. This learned Spaniard died in 1574. Sepulveda seems to have been a man of considerable literary merit; and Erasmus, who was no mean judge, pronounces him one of the best writers of his nation. Besides a number of works, which still lie in manuscript, his published writings were re-edited in 1780, in 4 vols. folio, by the Royal Academy of History of Madrid. This edition contained a sketch of the life and writings of the author.

SEQUANI, a Celtic nation of ancient Gaul, occupying part of the upper valley of the Saône or Arar, separated on the E. by the Jura range from the Helvetii; on the W. by the Arar from the Aedui, having the Leuci and the Lingone on the N., and the Allobroges and Ambarri on the S. They thus occupied the northern departments of Ain, Jura, and Doubs, with parts of those of Saône-et-Loire and Côte d'Or. Besides the Arar, the country was watered by the Dubis (Doubs), on which stood their chief town Vesontio, now Besançon. They fed large numbers of hogs, and exported ham and bacon to Rome. Before the conquest of Gaul by Cæsar, the Arverni and Aedui, the two most powerful nations of that country, were in a state of hostility; and the Sequani allied themselves with the former. In order more effectually to crush their enemies, these two nations hired a large body of Germans, under Ariovistus, from over the Rhine. With their assistance they totally defeated the Aedui; but the Germans seized for themselves a third part of the territory of the Sequani; and would have made further encroachments, had not Cæsar defeated them, and expelled them from the land. Though driven across the Rhine at that time, the Germans seem to have returned at a subsequent period.

SEQUESTRATION, in common law, is setting aside the thing in controversy from the possession of both the parties that contend for it. In this sense it is either voluntary, as when done by the consent of the parties; or necessary, as where it is done by the judge, of his own authority, whether the parties are inclined or the reverse. (See Bankruptcy.)

SEQUIN, or Zecchino, a gold coin of Venice, value about 9s. 6½d.

SERAGLIO (Persian *seraw*, or Turkish *serai*, both of which signify *a house*), is commonly used to express the house or palace of a prince. In this sense it is frequently used at Constantinople, where the houses of foreign ambassadors are called seraglios. But it is commonly employed by way of eminence for the palace of the grand signior of Constantinople, where he keeps his court, where his concubines are lodged (properly called *hareem*), and where the youth are trained up for the chief posts of the empire.

SERAING, a town of Belgium, on the right bank of the Meuse, in the province and 3 miles S.W. of Liège. It is chiefly remarkable for its immense iron-works, among which is probably the most extensive manufactory of machinery in the world. It occupies the former palace of the bishops of Liège, which has thus lost all its palatial and ecclesiastical aspect. Seraing has also iron-furnaces, forges, and coal-mines, employing from 3000 to 4000 hands, and a large number of steam-engines. Pop. 4857.

SERAMPORE, a town of British India, in the presidency of Bengal, and district of Hoogly, on the right bank of the Hoogly, 18 miles N. of Calcutta. It is a neat, clean, well-built place, somewhat like a European town. The principal building is the court-house, which was the government-house while the Danes possessed the town; and the chief manufacture carried on here is that of paper, which is

[1] For accounts of this great work see Fritsche in Herzog's *Cyclopædia*, "Alexandr. Bibelüber.," &c.

of good quality. Serampore belonged to Denmark till 1845, when it was purchased by the British, as it had proved very inconvenient by affording a refuge to swindlers and insolvent debtors from Calcutta. The place attracted more attention than it would otherwise have obtained, as being the seat of the first mission-station from Europe in India. It was founded by Wiliam Carey towards the close of the last century, and has since been removed to Calcutta. Pop. of the town and suburbs, 13,000.

SERAPIS. See Mythology.

SERES, a town of European Turkey, Macedonia, in the eyalet and 35 miles N.E. of Salonica, on the Strymon, in a plain rich in cotton and rice, and studded with numerous villages. It is well built and clean, with fine palaces, mosques, and gardens, large bazaars, and public gardens. Cotton-spinning is actively carried on here; and there is an extensive trade in corn, tobacco, and cotton. Seres is one of the most important commercial towns in Turkey. Pop. 30,000.

SERGEANT, or Serjeant-at-Law, or of the Coif, is the highest degree taken at the common law, as that of doctor is of the civil law; and as these are supposed to be the most learned and experienced in the practice of the courts, there is one court appointed specially for them to plead in, namely, the Common Pleas, where the common law of England is most strictly observed. But they are not restricted from pleading in any other court, where the judges, who cannot have that honour till they have taken the degree of sergeant-at-law, call them brothers.

Sergeant-at-Arms, or Mace, an officer appointed to attend the person of the king, to arrest traitors, and such persons of quality as offend, and to attend the lord high-steward when sitting in judgment on a traitor. There are four other sergeants-at-arms, created in the same manner; one, who attends the lord-chancellor; a second, the lord-treasurer; a third, the speaker of the House of Commons; and a fourth, the lord mayor of London on solemn occasions.

Common Sergeant, an officer in the city of London, who attends the lord mayor and court of aldermen on court days, and is in council with them on all occasions, within and without the precincts or liberties of the city.

Sergeant, in war, is a non-commissioned officer in a company of foot or troop of dragoons, armed with an halbert, and appointed to see discipline observed, to teach the soldiers the exercise of arms, and to improve their discipline. He receives the orders from the adjutant, which he communicates to his officers. Each company has generally two sergeants.

SERGEL, Johann Tobias von, an eminent Swedish sculptor, was born at Stockholm on the 8th of September 1740. He was at first apprenticed to a stone-mason, and was engaged in that capacity at the royal palace of Stockholm, where he had the good fortune to draw upon himself the notice of the sculptor L'Archeveque, who at once took him as a pupil. After assisting his master for some years he obtained, in 1767, a travelling pension, when he went to Rome, and remained there for twelve years. During his stay in Italy he executed numerous works of great merit; and, on his visiting Paris, his "Othryades," or the figure of a wounded Greek soldier, now placed in the Luxembourg, gained him admission to the Academy of the Fine Arts. He had just reached London when he received an offer from Gustavus III. of Sweden of the office of court sculptor. He lost no time in reaching Stockholm, and in 1784 accompanied his majesty to Rome, and induced him to purchase the celebrated "Endymion" for the royal museum of Stockholm. Catherine II. of Russia was anxious to secure the services of Sergel, and made him very flattering offers to go and reside at St Petersburg. But the sculptor was too much attached to his master to think of leaving him; and when, in a few years, the untimely end of Gustavus cast a gloom over all the court, it plunged Sergel in so deep a melancholy that he is reported never to have recovered. He died in his native city on the 26th of February 1814, in his seventy-fourth year.

Sergel's works are all marked by great vigour of conception, by simplicity, and grace of style, and by an entire freedom from the mannerism which tainted the most graceful productions of the chisels of his cotemporaries. His best statues are his "Karl III.," "Juno," "Cupid and Venus," "Diomedes carrying off the Palladium," "Othryades," "a Faun," "Gustavus III., "Oxenstierna," "Mars and Venus," and a "Venus Callipyge." He executed a number of excellent groups, and some fine busts and portrait medallions.

SERGIPE, or Sergipe del Rey, the smallest of the provinces of Brazil, bounded on the N. by that of Alagoas, E. by the Atlantic, S. and W. by the province of Bahia, lying between S. Lat. 9. 15. and 11. 27., W. Long. 36. 20. and 39. 15. Area, 11,079 square miles. It extends for 110 miles along the coast, and nearly 140 inland. The coast line is in general low and sandy, and the surface of the country is level, except where it is broken by a few hills. These occur chiefly in the western part of the province, and are generally covered with forests. The largest river is the São Francisco, which flows eastwards into the Atlantic, forming the northern boundary of the province. The Itapicuru forms the southern boundary, flowing in the same direction; and the country is also watered by the Vazabarris and Sergipe, which also fall into the Atlantic. Rock-crystal, limestone, and saltpetre are the principal minerals found here. The soil on the whole is not remarkable for its fertility; for although the eastern portion produces rice, cotton, sugar-canes, tobacco, flax, and other crops in abundance, the western part of the province is of a very sterile and unproductive nature, being in many places stony, and throughout ill supplied with water. The rivers and lakes, of which there are several in the N.W., abound in fish, and the latter also in wild-fowl. Cattle, mules, and horses are reared in considerable numbers. The forests furnish valuable timber and dyeworks. Among the exports of the province the most important are cotton, sugar, brandy, tobacco, and cattle. The mouths of the rivers form many harbours along the coast, but they are in general small and shallow. Sergipe is divided into five comarcas and seventeen districts. It returns two senators and four deputies to the Brazilian legislature. The capital is Sargipe or São Christovão, a town of 3000 inhabitants, on the Atlantic coast. Pop. (1856) 183,600.

SERICA, the name given by the ancients to a tract of Eastern Asia, lying, according to Ptolemy, east of Scythia extra Imaum, north of India, and west of the land of the Sinae. It probably occupied the country now called Mongolia, and the western part of China. The people were called Seres, and were chiefly known to the Greek and Roman nations on account of the silk which they produced, and in which they carried on a lucrative trade. Indeed, so closely were they connected with this branch of trade that the classical name for a silkworm was *ser*, and for silk-cloth *serica vestis*. Some have supposed that the name of the insect was transferred to the people; but this is not so probable as the converse, for there are many instances of articles of commerce deriving their names from the places whence they come. According to the ancient accounts, the Seres were a mild and gentle people, avoiding as much as possible (like the Chinese of the present day), all intercourse with other nations. They were probably of the Mongolian race.

SERINAGUR. See Sireenuggur.

SERINGAPATAM (*Shri Ranga Patanam*, the city of Shri Ranga or Vishnu), a town of India, in the Rajah of

Mysore's dominions, 9 miles N.E. of Mysore, and 248 west of Madras, on the west end of an island in the Cauvery, N. Lat. 12. 25., E. Long. 76. 45. It is now a dull, deserted town, the mere ghost of its former magnificence, when it was the capital of Mysore and residence of Tippoo Sultan, with a population, it is said, of no less that 300,000. The fortifications, which are very strong, though not skilfully constructed, form an irregular pentagon, protected on two sides, the N. and S.W., by the river, and extending a mile and a half in length, from N.W. to S.E., by half that breadth. The strongest parts of the defences were towards the east and south, the safety of the other sides having been too much trusted to the Cauvery, though that river is fordable in the dry season. It was from this side that the town was stormed by the British in 1799, in preference to making a breach in the massive walls on the land side. The grass and trees now grow luxuriantly about the place where the deadly conflict took place, and where Tippoo himself fell. The principal buildings within the fortifications are the large, straggling, mean-looking palace, now in a state of decay; the Hindoo temple of Vishnu, and the sultan's mosque, containing the tombs of the nobles who fell in his cause, and commanding a fine view from its minarets. Seringapatam is said to have been founded in 1454 by a devotee of Vishnu. Its early history is involved in obscurity; but in 1610 it was possessed by Raj Wadegar, a Mysore chief. In 1697 it was besieged, but ineffectually, by the Mahrattas; and again, in 1772, after it had been for seven years occupied by Hyder Ali as his capital, these formidable assailants were bought off by a sum of L.150,000. Tippoo Sultan, the son and successor of Hyder Ali, also resided in Seringapatam, and erected the formidable defences of the town. On the 5th of April 1799 it was invested by the British, and on the 4th of May taken by storm. The town and fort were retained for some time as a military station, but afterwards abandoned on account of their insalubrity. The population in 1800 was 31,895; at present it is only 12,744.

SERINO, a town of the kingdom of Naples, province of Principato Uttra, on the Sabbato, 6 miles S.S.E. of Avellino. It consists of several adjacent villages, containing churches, convents, an hospital, and manufactures of hardware. Pop. 8000.

SERMIDE, a town of Austrian Italy, in the province and 27 miles S.E. of Mantua, on the right bank of the Po. It contains churches, public offices, and a court of law. Weaving and dyeing are carried on here. Pop. 5594.

SEROHEE, a town of India, capital of a state of the same name, in Rajpootana, 67 miles N.E. of Nusseerabad. It covers a large extent of ground, and contains many good brick-houses; but much of the town is uninhabited. The chief building is the palace of the rao or chief, which stands on a small hill, but is of no great beauty. Serohee has become, since it was taken under the British protection, a place of much commerce and wealth; and it is especially celebrated for the manufacture of sword-blades. The state of Serohee is bounded on the W. and N. by that of Joudpore, E. by Godwar and Oodeypore, and S. by the Guicowar's dominions. It has an area of 3024 square miles. The eastern and south-eastern parts are mountainous; the country has a general slope towards the N.W., and is watered chiefly by affluents of the Loni, which flows in that direction into the Gulf of Cutch. Mount Aboo, in this country, reaches the elevation of 5000 feet above the sea. There are many ruins, and other traces of the former civilization and prosperity of the country. Serohee was formerly joined to Joudpore; but is now independent, and since 1823 has been protected by the British.

SERON, a town of Spain, Andalusia, in the province and 28 miles N. of Almenia, on the right bank of the Almanzor. The principal buildings are a church, several hermitages, a court-house, and prison; and the manufactures of the town comprise linen, blankets, and earthenware. There are also oil and flour mills. The surrounding region is rich in iron, lead, and copper; and there were formerly many smelting places for these metals, but only two are now used. Nitre and white marble are also obtained in the vicinity. Pop. 5619.

SERPA, a town of Portugal, in the province of Alemtejo, on a height near the Guadiana, 17 miles E.S.E. of Beja. It is pretty well built, walled, and entered by five gates. There are here two churches, a castle, schools, and hospitals. Some contraband trade is carried on with Spain. Pop. 5600.

SERPENT, a powerful bass musical instrument of the wind kind, invented by a French priest at Auxerre in 1590. See the article MUSIC.

SERPENTINE VERSES begin and end with the same word; as, "Ambo florentes ætatibus, Arcades ambo."

SERPENTS. See REPTILIA.

SERPUCHOV, a town of European Russia, in the government and 56 miles S.S.W. of Moscow, at the point where the Nara and Serpeika fall into the Oka. It has a citadel, which stands on an eminence, and is surrounded by high walls now falling into decay. There are in the town a cathedral and numerous other churches, various public edifices, schools, and charitable institutions. Sailcloth, leather, paper, and tiles are made here; weaving is also carried on; and there is a considerable trade in corn, timber, cattle, tallow, hemp, &c. The town is very ancient, having been in existence as early as 1328. Pop. (1850) 12,196.

SERRA CAPRIOLA, a town of the kingdom of Naples, province of Capitanata, on a hill looking down upon the Fortore, 13 miles N.W. of San Severo. It is a small place, with several churches, convents, an hospital, &c. Near it are ruins, supposed to be those of the ancient Teate. Pop. 4000.

SERRANUS, JOANNES, or *Jean de Serres*, a learned French Protestant, was born about 1540 at Villeneuve-de-Berg. He acquired the Greek and Latin languages at Lausanne, and devoted himself to the study of the philosophy of Aristotle and of Plato. On his return to France he studied divinity, and in 1574 he began to distinguish himself by his writings, but was obliged to forsake his country after the dreadful massacre of St Bartholomew. He became minister of Nismes in 1582, but was never regarded as a very zealous Calvinist. He has even been suspected, though without reason, of having actually abjured the Protestant religion. He was one of the four clergymen whom Henry IV. consulted about the Catholic religion, and who returned for answer, "that Catholics might be saved." He wrote afterwards a treatise in order to reconcile the two communions, entitled *De Fide Catholioo, sive de Principiis Religionis Christianæ, communi omnium Christianorum consensu, semper et ubique ratis*, 1607. This work was disliked by the Catholics, and received with such indignation by the Calvinists of Geneva that many writers have affirmed that they poisoned the author. It is certain at least that he died at Geneva in 1598. His principal works are—A Latin translation of Plato, published by Henry Stephens; *A treatise on the Immortality of the Soul; De Statu Religionis et Republicæ in Francia; Mémoire de la Troisième Guerre Civile et derniers Troubles de France sous Charles IX.*, &c.; *Inventaire Général de l'Histoire de France, illustré par le Conférence de l'Eglise et de l'Empire; Recueil des Choses Memorables avenues en France sous Henry II., François II., Charles IX., Henri III.* These three historical treatises have been justly accused of partiality and passion; faults which it is next to impossible for a contemporary writer to avoid, especially if he bore any part in the transactions which he describes.

His style is incorrect and inelegant; and he has been accused by his enemies of making numerous mistakes and mis-statements of facts.

SERRAVALLE, a town of Austrian Italy, Venice, in a mountain valley on the Maschio, 24 miles N. of Treviso. It has a large market-place, a cathedral, and other churches, convents, schools, and an hospital. Woollen and silk stuffs, as well as paper, are made here; and there is a considerable trade in corn, wine, and honey. Pop. 5131.

SERTORIUS, QUINTUS, a clever Roman adventurer, was born of respectable parents at the Sabine village of Nursia, late in the second century before Christ. He gave early marks of being a ready speaker and skilful manœuverer, who, to great personal strength, added a stubborn endurance of fatigue. He commenced his military career in Gaul, where, in the bloody battle fought on the Rhone, B.C. 105, he was wounded, and saved his life by swimming across the river, clad in complete armour. Sertorius continued to distinguish himself, now by entering the Teuton camp at Aix as a spy, again by massacring the inhabitants of the town of Castulo in Spain, and anon, after repeated provocation, by spearing 4000 of those slaves whom Marius kept about him as a body guard. In 83 B.C. he was raised from the office of quæstor to that of prætor. After trying, ineffectually, to check the progress of Sulla on his return from the conquest of Mithridates, Sertorius was advised to betake himself to Further Spain, where he could administer the affairs of that province in comparative peace. With a handful of men, and very little means, he made his way to Spain, where he set about raising an army of Roman settlers and Spaniards, and equipping a fleet. While thus engaged, Luscus was despatched by Sulla to oppose the progress of Sertorius. The agile adventurer immediately put to sea, but was attacked by an overwhelming number of Mauritanians, and compelled to scud for the Pityussæ Islands, where he was joined by some Cilician rovers, who aided him in extinguishing the Roman garrison. Attacked by the fleet of Luscus, and his light ships being harassed by stormy weather, he was forced to land at the mouth of the Guadalquiver, after a wild passage through the Straits of Gibraltar. Having met some seamen who had just arrived, it was said, from the *Insulæ Fortunatæ*, Sertorius is reported to have contemplated setting out for those "Happy Isles," where he might spend the rest of his days far away from the strife of men. Ambition, as it generally does, urged him on to his end. He now turned on his former opponents, the Mauritanians, and took their king, in the city of Tingis, or Tangier. He afterwards went to aid the Libyans against the Romans. While in Africa he was presented with a fawn, which in time became so tame as to accompany its master wherever he went. The influence of this creature on the superstitious inhabitants of his camp is reported to have been very great. This "fawn of Sertorius" has become famous in literary as well as in political history. Corneille made it the subject of a tragedy, and R. H. E. Landor, in modern times, has chosen it as the subject of a tale. Sertorius had now to face the Roman forces under Metellus and Pompeius. To recount the endless manœuvres and skirmishes of his guerilla warfare, how suddenly he swept down upon the foe, like a beast of prey, at dusk; how nimbly he withdrew his handful of men as the sleepy foe roused themselves to the full danger of their situation; how quickly he would cross the sierras of Spain with his little band, as if their course was aided by the upper denizens of the air, would be much more than we here have space for, and it must accordingly be sought out in Plutarch's life of Sertorius. In these raids there was often much bloodshed, and Sertorius generally came off with the victory. Some say this active adventurer in time became lazy, and indulged himself with women and wine. It is very certain that his cruelty and suspicion became greater, and not altogether without cause. He had taken Spaniards for his guard, in distrust of his own countrymen. These Iberians were by no means satisfied with the humble rank assigned to them. Yet they were Romans who conspired against him. Invited to a banquet by his own generals, he was suddenly stabbed by Marius Antonius, B.C. 72. Thus ended the war of Sertorius, and Spain now passed into the peaceful possession of Rome. The curious will find considerable resemblance between the exploits of this ill-fated Roman adventurer and an English nobleman, Mordaunt, Earl of Peterborough, who achieved such astonishing deeds of arms in the Spanish peninsula during the reign of Queen Anne.

SERVAN, ST, a town of France, in the department of Ille-et-Vilaine, on the south side of the harbour of St Malo, at the mouth of the Rance, in the English Channel. It is a suburb of St Malo, and a favourite watering-place. The most remarkable building is an isolated tower, now used as a prison. This edifice stands on a rock, between the two harbours, and is approached by a drawbridge. One of the harbours is suitable for large, the other for small vessels. Shipbuilding is carried on here; many of the inhabitants are employed in cod-fishing; and there is a considerable trade in beer, wine, brandy, ship-biscuits, cordage, &c. Pop. 10,257.

SERVANDONI, GIOVANNI GERONIMO, a celebrated architect, was born at Florence in 1695. He rendered himself famous by his exquisite taste in architecture, and by his genius for decorations, fêtes, and embellishments. He was employed and rewarded by most of the princes in Europe. In Portugal he was honoured with the order of Christ. In France he was architect and painter to the king, and member of the different academies established for the advancement of these arts. He received the same titles from the kings of Britain, Spain, Poland, and from the Duke of Wirtemberg. Notwithstanding these advantages, his want of economy was so great that he left nothing behind him. He died at Paris in 1766. Paris is indebted to him for many of its ornaments. He made decorations for the theatres of London and Dresden. He was permitted to exhibit shows, consisting of ornamental decorations. Some of these were exceedingly grand; his "Descent of Æneas into Hell" in particular, and his "Enchanted Forest," are well known. He built and embellished a theatre at Chambor for Marshal Saxe, and furnished the plan and model of the theatre-royal at Dresden. He was employed frequently by the king of Portugal, to whom he presented several elegant plans and models. The Prince of Wales, too, the father of George III., engaged him in his service; but the death of that prince prevented the execution of the designs which had been projected. He presided at the magnificent fête given at Vienna on account of the marriage of the Archduke Joseph and the Infanta of Parma.

SERVANT. See MASTER AND SERVANT.

SERVETUS, or SERVETO, *alias* REVES, MICHAEL, a learned Spanish physician, and a renowned heretic, was born at Villanova, in Aragon, in 1509. His father, who exercised the profession of a notary, early designed him for the church, but subsequently perceiving in him a decided taste for theological speculation, and an open hostility to scholasticism, he deemed it more prudent to educate him for the law. In 1528 he went to the University of Toulouse, where he formed a connection with some inquiring youths who had become interested in the Lutheran innovations. On his leaving Toulouse in 1530, he found himself an ardent reformer, and set out for Italy and Germany to publish his new doctrines. Taking up his residence at Bâle, near Œcolampadius, he was at first well received by that reformer. Servetus, however, in his youthful zeal, had driven his speculations much too far for the

purposes of the Reformation, and Œcolampadius, on becoming aware of his views regarding the doctrine of the Trinity, is said at once to have withdrawn his friendship from him. A like reception awaited him at Strasbourg from Bucer and Capito. Hope was high, and intellectual strength was unquestionable in Servetus; he accordingly resolved to publish a book regarding the Trinity, which appeared at Haguenau in 1531, under the title of *De Trinitatis Erroribus, Libri vii.* This was followed up by another publication next year, entitled, *Dialogorum de Trinitate, Libri duo,* and with an appendix, consisting of *De Justicia Regni Christi, capitula quatuor, Per Michaelem Serveto, alias Reves, ab Aragonia Hispanum,* 1532, in which he came forward with those theories which were subsequently more fully developed in succeeding publications. These feelers which Servetus had cast out brought in rather alarming intelligence, which prompted him at once to change his place of residence, his profession, and his name. He accordingly packed up for France in 1533, under the title of Villanovanus, and settled in Paris, where he studied medicine with brilliant success. Having graduated in medicine, he wrote a learned book, entitled, *Ratio Syruporum,* which he gave to the world under the authorship of Michael Villanovanus. Servetus could not be at peace. His ever active intellect, and his restless desire for controversy, got him into endless difficulties. Having quarrelled with the physicians of Paris, he wrote an *Apologia,* which was suppressed by order of parliament, and Servetus, judging discretion to be the better part of valour betook himself to Lyons in 1535. Here he engaged with an eminent printing firm of the day to correct the press, and during his residence here he published, with characteristic notes, a good edition of Ptolemy's *Geography.* The medical hostility which his presence had engendered in the capital having now died out, he set out for Paris in 1537, where he taught geography, mathematics, and even astrology, with success. The last branch of knowledge not being quite to the taste of the doctors of the Sorbonne, drew down upon the head of Servetus another sentence of the parliament. The ubiquitous Spaniard forsook the capital for ever, and took up his residence at Charlieu, near Lyons, where he began practice as a physician. In 1540, solicited by the invitations of the Roman Catholic Archbishop, Pierre Paumier, whom he had formerly met in Paris, he was induced to exchange his residence for Vienne, in Dauphiné. Here he was diligent in the pursuit of his profession of a physician, and filled up his leisure hours with literary work for the booksellers of Lyons. It was during this time he published his edition of the Bible in Latin, with a preface and notes.

Theology, which he had ostensibly exchanged for medicine, was nevertheless his darling study. He allowed few days of his life to pass by without seeing a new theological speculation raised or completed. His mind had now become mature, and his circumstances were prosperous; why should not he endeavour to urge on the Reformation of Christianity which had already been begun, but which had not, in his estimation, gone anything like so far as truth would warrant? Why should not he make himself a name that would be remembered as well as Luther and Calvin, when he should no longer be known? Why, in short, should not he give publicity to those opinions which he knew only too well how to maintain, and which few men could surpass him in ingeniously, and even sophistically, defending? Some, or all of these motives, doubtless actuated the subtle and ambitious heretic, and he resolved now to put himself in communication with the great Genevan divine, and see what would come out of it. Some say he had known Calvin in Paris, but it is most probable his knowledge of him was merely epistolary. After the exchange of some preliminary courtesies, Servetus asked Calvin's judgment of a portion of his future volume *Christianismi Restitutio.* The Reformer combated very sharply this portion of his lucubrations, and Servetus replied with all the cool bitterness of a thorough-paced controversialist This was what Calvin was not prepared for, and possibly his temper had become more than ruffled by the rude manner of the Spanish doctor. In Calvin's letter to Farel, of 13th February 1546, he thus writes of Servetus:—"He offers to come hither, if I please. But I do not wish to pledge my word for his safety; for if he come, I shall not suffer him to depart alive, if my influence be of any avail." (Calvin's *Letters,* vol. ii., 1857.) This is very definite. Servetus now had recourse successively to Abel Popin, a pastor at Geneva, and to Pierre Viret, pastor at Lausanne, without any better result. He had now completed his *Christianismi Restitutio,* and Marinus, a German publisher at Bâle, got the first offer of it. The German was too wary to engage in any such enterprise, and Servetus had accordingly to prevail upon a bookseller in Vienne secretly to engage in the printing of it. The work was gone about with due caution, and on its publication in 1553, it was forwarded to Frellon, publisher in Lyons, who had formerly employed Servetus, and through whom the Spaniard had corresponded with Calvin. It was through this man, it is reported, that Calvin came by his copy of the work of Servetus; others say it reached him through the ordinary channels of the trade. At all events, De Trie, then residing at Geneva, and a friend of the Reformer, sent to a Lyonese the first sheet of this work, and pronounced Servetus the author. More letters came to Lyons, in which were some of those sent to Calvin by Servetus himself. The upshot was that the engines of the Inquisition were set in motion, and had not the Spaniard escaped from the prison in which he was confined in Vienne, he would, without doubt, have suffered the extreme penalty of the law. The ordinary tribunal of the Bailiwick of Vienne sat in judgment on the outlaw, and condemned him to the flames on the 17th of June 1553. So far as it is possible to ascertain anything with regard to the opinions promulgated in the *Christianismi Restitutio,* they seem to have been decidedly anti-Trinitarian. The author sought to bring men back to the simple faith of primitive Christianity, which, in his opinion, both the Reformed and Roman Catholic churches had forsaken. What galled Calvin perhaps nearly as much as the doctrines the book contained was the spirit in which he, the Reformer of Geneva, was spoken of in that publication. It is difficult on any other assumption to account for his singular animosity against Servetus. All the accustomed respect paid to Calvin was here treated with derision, and he was plied at once with the most ingenious arguments and handled with the most scurrilous abuse.

For a time Servetus lay concealed in the French territory, but subsequently taking courage, he set out for Geneva, and arrived there towards the end of the month of July, on his way to Italy. It is not certain by whom he was recognised; some would have it by Calvin himself. But this seems doubtful. The words of the *Procès* are, "M. Servetus was recognised by some brethren." Calvin instructed his servant, Nicolas de la Fontaine, to have him imprisoned, and to stand security according to the *lex talionis,* then a judicial usage in Geneva. Calvin writes, in his letter to Farel of the 20th August 1553, "Nicolas was released from prison on the third day, having given up my brother as his surety; on the fourth day he was set free." (Calvin's *Letters,* vol. ii., 399.) The forty charges brought against Servetus had been found proven by the Senate. Calvin says in the same letter, "I hope that sentence of death will at least be passed upon him; but I desire that the severity of the punishment may be mitigated." The Senate of Geneva, despite the remonstrances of Calvin to the contrary, resolved to lay the case before

the Swiss Churches of Berne, Zurich, Schaffhausen, and Basle. Calvin now busied himself in writing to the leading brethren of the several churches regarding the criminality of Servetus. He urged upon them, with more than ordinary warmth, the necessity for giving a judgment which should at once rid the church and the world of this man and his "detestable mockeries." The churches were unanimous in their verdict of the theological culpability of Servetus, and mildly exhorted their Genevan brethren to rid the church of this noisome pest. (See Calvin's *Letters*, vol. ii., p. 417.) After such replies the decision could not be long doubtful. Yet the sentence which was pending has been denominated by Lord Brougham, the greatest lawyer of the present generation, as "a mockery of a trial." On the 27th of October 1553, Servetus was led forth to hear his doom pronounced. He had escaped the terrors of the Inquisition at Vienne, only to meet death at Geneva. From the site where the fatal pile was erected beyond the walls of the city, he bequeathed with his breath a mournful souvenir to the Reformation, and an eternal subject of accusation to the enemies of Calvin. Persecution was the sad legacy left by the middle ages to Christian communities. The error of Calvin in the death of Servetus was the error likewise of Bucer, of Œcolampadius, of Melanchthon, and of Bullinger, for they all agreed in the sentence of condemnation pronounced upon the unfortunate Spaniard. Hence, while one cannot but deplore the error into which they were led, and feel a just pity for a great victim, respect for the memory of the Reformers whom an unhappy time made the accusers and judges of Servetus cannot but commingle with that righteous indignation which every one must feel at such an enormous departure from the principles of enlightened justice.

Many copies of the *Christianismi Restitutio* had been conveyed to Frankfurt for the Easter fairs; and Calvin lost no time in sounding the alarm to the pastors of that church to have them instantly and entirely destroyed. So successfully was the work done, that only *three* copies of the book are now in existence, one in the Imperial Library of Paris, another in that of Vienna, and a third in a private collection. (See Rilliet, *Relation du Procès de Servet*, p. 9, 1844.) Among other curious things contained in this very rare book, there is an important theory regarding the circulation of the blood. Servetus held, in opposition to all physicians of his day, that the whole mass of the blood passes through the lungs by the pulmonary artery and vein. From this suggestion Harvey had only to advance a single step to render himself immortal. (The chief authorities for the life of Servetus are De la Roche, 1712; Mosheim (in German), 1748; Treschel (in German), 1839; and Rilliet (in French), 1844, translated by Tweedie, 1846; besides the latest published authority, in Calvin's *Letters*, 1857.)

SERVIA (Turkish *Syrp*, Slavonic *Serbia*), one of the Danubian principalities, nominally included in the Ottoman empire, but in reality only tributary to that power; lying between N. Lat. 43. 2. and 44. 58., E. Long. 19. 10. and 22. 20.; bounded on the N. by the Austrian dominions, E. by Wallachia and Bulgaria, S. by Rumilia and Albania, and W. by Bosnia. Length from E. to W., 160 miles; greatest breadth, 200; area, 21,152 square miles. The country is very mountainous, having a general inclination towards the north, where the Danube flows along the frontier, and receives all the running water of the country. The mountains consist of northern branches of the Balkan chain, and are the most considerable offshoots of that range, being higher and more numerous than those either in Bulgaria to the east or Bosnia to the west. The extreme S.W. of the principality is also occupied by an offshoot of the Dinaric Alps, which divides the waters of the Drina from those of the Morava. The whole country is traversed by ridges extending from south to north, forming between them numerous narrow valleys, which seldom expand into plains. The passes over the mountains towards the south are very difficult, even for foot-passengers and beasts of burden. Indeed, in this direction, there extends an almost unbroken mass of ridges and plateaus, as far as the borders of Macedonia, Albania, and the Herzegovina. At the north-eastern corner of the land a branch of the Carpathian Mountains extends down to the Danube, forming the division between Wallachia and the Austrian empire. On the north and east Servia is bounded by the Danube and its affluent the Save. The former river touches the boundary at Belgrade, where it is joined by the Save from the west. It then flows eastward as far as Orsova, where it turns to the south, and separates Wallachia from Servia. It receives from the south the Morava, which is formed by the confluence of the Bulgarian and Servian Morava; and the Timok, which, for a short distance, separates Bulgaria from Servia. The chief affluents of the Save are the Drina, forming the frontier of Servia towards Bosnia and the Kolubara. The scenery of Servia is exceedingly beautiful; for the mountains are almost all covered with dense forests of oaks and other trees; the valleys and rivers form an endless and agreeable diversity; and the lower ground is exceedingly fertile, covered in many places with rich meadows, and in others with fields of Turkish wheat, which grows most luxuriantly. The mountains of Servia are very rich in minerals, such as gold, silver, copper, iron, loadstone, lead, and coal; and the forests abound in valuable timber. The country is, however, little cultivated, and scantily peopled; and its great resources want the hand of industry to develop them. Wolves, bears, foxes, deer, and hares, are the most numerous wild animals of the land. Fish abound in the rivers; and silk-worms and bees are reared in large numbers. Corn is grown chiefly in the valleys of the Morava, Save, and lower Drina; and notwithstanding the defective system of cultivation, the quantity raised is more than sufficient for the wants of the country. Vines are cultivated along the banks of the Danube. On an average there is more red than white wine produced; but the white grapes of Semendria, from vineyards said to have been originally planted by the emperor Probus, are highly esteemed. Tobacco, hemp, and various kinds of fruit, especially plums, are also grown in different parts of Servia. Various measures have been adopted by the government for the improvement of the cultivation of the country, by the establishment of agricultural schools, and of a model farm; but the effect of these has not yet been apparent. The rearing of cattle is one of the most important sources of wealth to the country; and live stock form one of the most considerable exports of the country. The horses are of good breed, but more remarkable for strength and endurance than for beauty. Horned cattle are chiefly used here in the labour of the farm; and the sheep, which are numerous, supply the people with milk, butter, cheese, and wool. The rearing of swine is very profitable, and is spread over all the country. Manufacturing industry is in Servia still in its infancy, and is somewhat discouraged by the little demand that there is for manufactured goods. But the Servians have a great aptitude for mechanical employments, and produce many articles of excellent construction. The women weave, during the winter, linen, woollen, and silk cloth, to supply the wants of the whole family; and many of the men are employed as masons, carpenters, tilers, smiths, millers, tailors, &c. There is a government printing-office at Belgrade, a cloth factory at Topdschider, a glass-work at Jagodina, a foundry at Kragujewaz, and an extensive powder-mill at Stragari. The trade with foreign countries is very active, and daily increasing in importance. Owing to the very limited demand for articles of foreign produc-

tion, the exports greatly exceed the imports. The principal articles of export are cattle, pigs, leeches, hides, wool, tallow, wax, and honey. The chief places of trade are Belgrade, Jagodina, Schabaz, Negotin, and Aleksinaz. For year ending 31st October 1857 the total imports were, L.548,000; exports, L.740,000; goods in transit, L.206,600. Of the imports, L.412,000 were from Turkey, and L.133,000 from Austria; of the exports, L.173,800 were to Turkey, and L.552,000 to Austria.

The country suffers from the want of good means of communication. Of the navigable rivers in the land, only the Danube and the Save are used for purposes of traffic; but the full freedom of navigation on these rivers is secured as a fundamental privilege of the nation. Freedom of trade is also secured as a national right to all Servians, not only in their own country, but in the whole Ottoman empire. Servia has no coinage of its own; but Austrian, Turkish, and Russian moneys are in circulation. Public education is one of the chief objects of attention to the government; but it is still in a very backward condition. The parish schools are supported by each separate parish, and the higher institutions by the government. Of the former there ought by law to be at least one in each parish, but in many places this is not the case. The higher schools comprise four gymnasia, two schools of art, and one of agriculture; a lyceum, with faculties of law, natural science, and philosophy; a theological seminary; and a military academy. The number of scholars attending these various institutions in 1855 was 11,281, of whom by far the greatest number belonged to the parish schools. There is one learned society, the Society for Servian Literature in Belgrade. In 1856 there were published in the country 3 journals, which had 1450 subscribers; and there were introduced from other countries 6 Slavonian, 84 German, 7 English, 21 French, 4 Italian, 2 Hungarian, and 1 Turkish newspaper. The religion of the great majority of the people is that of the Greek Church; and the national Church of Servia acknowledges its canonical dependence on the Constantinopolitan patriarchate by an annual remittance of 9000 piasters (about L.90). The archbishop of Belgrade enjoys the title of Metropolitan of Servia, and the supremacy over the three bishops who form with himself the National Synod, the highest ecclesiastical court in the country. Each bishop presides in a diocesan consistory; and all the prelates are appointed from the monastic order by the synod, with the concurrence of the prince. The number of the inferior clergy is 651, and that of the convents 38. Roman Catholics and Protestants are allowed to establish congregations, and to manage independently their church and school funds; but any secession from the national church is rigorously forbidden. Jews and Mohammedans are permitted the free exercise of their religion. Servia forms an integral part of the Turkish empire, but stands to it in a peculiar relation of dependence, according to which the nation and its prince are bound to loyalty and obedience to the sultan, and to the payment of an annual tribute of 2,300,000 piasters (about L.23,000); while, on the other hand, the Porte guarantees to the principality full internal sovereignty, the free election of their princes, an independent national government, full freedom of religion, legislation, trade, and navigation, and the right to maintain a national defensive force. The dignity of prince is hereditary in the male line, and was settled in 1842 on the family of Alexander Georgewitch. The Turks in the country are immediate subjects of the Porte; and there are 7 Turkish fortresses, 5 under the governor of Belgrade, and 2 under the Pasha of Widdin. The power of the prince is limited by a senate of 17 members, which possesses the chief legislative powers; and there is also a general assembly of the people which meets from time to time; but the extent of its powers is not accurately defined. There is no distinction of ranks, except what is derived from occupation. Most of the people are Servians, but the country also contains about 106,000 Wallachians, a few thousand Bulgarians, 16,000 Turks, about 1800 Jews, 18,000 gypsies, and about 6000 European foreigners. The country is divided into 17 circles, exclusive of the city of Belgrade; and it contained, in 1854, 39 towns, 2306 villages, and 160,294 houses. The total population in the same year was 1,029,082; the number of births, 34,167; of marriages, 11,863; and of deaths, 26,894. The annual average for 1837–53 was 1 birth to every 28·3 persons; 1 marriage to every 97; and 1 death to every 43·5; and the average annual increase of the population was 1·23 per cent.

The territory of Servia formed part of the Roman empire, and was included in the province of Upper Mœsia. From their conquerors, the original inhabitants received by degrees the benefits of civilization and Christianity; but both of these were exposed to many dangers from the inroads of the barbarians. Attila, and after him Theodoric, severely afflicted the country; but it gradually recovered from these misfortunes, and was again united to the Roman empire of the east. Afterwards it was ravaged by the Avars; and, finally, about the middle of the seventh century, the Serbs or Servians entered and occupied the land which they still possess. They spread themselves, however, over a much wider region, extending from the Euxine to the Adriatic, and from the Danube far into the valleys of the Balkan. Nominally under the protection of the Byzantine empire, they derived little advantage from that circumstance, in their constant wars with the Bulgarians and neighbouring Slavonic nations; and they made many attempts to attain an independent position. These efforts were at last successful in 1217, when Pope Honorius erected Servia into a kingdom, independent alike of Hungary and the Eastern Empire. The greatest of the monarchs of Servia was Stephan Duschan. At his coronation in 1333, he was acknowledged as the feudal lord of Ragusa, and his authority extended over Ætolia and Macedonia. He assumed the title of king and emperor, and bore on his banners the imperial double eagle. Before his death in 1356, the Servian sway extended over Bulgaria, Bosnia, Dalmatia, and a part of Albania; and he had even hoped, at the head of 80,000 men, to put a final end to the Byzantine empire. But he was cut off by death, and the monarchy began thereafter to decline, and was unable to stand before the advancing arms of the Turks. In the very year of Stephan's death, these formidable opponents first gained a firm footing in Europe; and in 1389, Lazarus, the last king of Servia, was beheaded in the tent of Amurad I., after the bloody battle of Amselfeld. Another victory gained by the Turks on the same field, sixty years later, brought the country completely under their power. Servia was, however, afterwards the scene of many contests between the Christian and the Turks, and contains the battle-fields of Batucsina (1689), Nissa (1689), Belgrade (1717), Groczka (1739), and others. The country remained under the Turkish yoke till the beginning of the present century; but at last the oppression which they suffered drove the people to rebellion. The first leader who raised the standard of independence, in 1801, was George Petrowitch, surnamed Czerny, or the Black. The Servians flocked to his standard, speedily drove the Turks to take refuge in the fortresses, and proceeded to besiege these. In 1806 they totally defeated a large Turkish army at Schabaz, soon after took Belgrade, and before the end of 1807 were in possession of the whole country. In 1811 George Czerny was appointed Prince of Servia; but not recognised by the Porte, and the conditions offered by that power in 1812 not being accepted, a fresh war ensued, which terminated unfavourably for the Servians. George Czerny had to flee, and the country was again re-

duced under the Turkish sway. Another leader rose up in the person of Melosch Olrenowitch, who restored, in some measure, the independence of his country, and concluded a treaty with the Porte in 1815. Two years later, George Czerny, returning to the country, was put to death by order of Melosch, who was determined to avoid any precipitate measures of hostility to the Turks. In 1827 Melosch was appointed Prince; but in 1839 he was forced to abdicate this dignity. Upon this, various contending factions strove for the supreme power in Servia; but, finally, a general assembly of the people, in 1842, elected Alexander Georgewitch, son of George Czerny, to be hereditary prince, and this choice was subsequently ratified by the Porte. The principality of Servia, which had previously been under the protection of Russia, was by the treaty of Paris, in 1856, placed under the collective guarantee of the contracting powers in that treaty.

SERVICE, Choral, in the Romish Church, &c., consists of a certain order of antiphonies and psalms sung to what is called *canto fermo* in Italian, *canto llano* in Spanish, and *plain-chant* in French. This kind of chant, in its simplest form, consists of slow sounds of equal duration, and without any embellishment, sung in unisons and octaves. In other cases the *canto fermo* is accompanied by parts in harmony, but always with due regard to a certain *antique* and very simple style of melody and of harmony, which is founded upon the peculiar *tonality* and *cadences* of the *canto fermo*, and without which it loses its characteristic effects. The *canto corale*, or choral chant, is often particularly named *canto Gregoriano*, or Gregorian chant, from the great pains taken by St Gregory, in the sixth century, to improve and to teach to his pupils the oriental church chants derived from the Greeks. St Ambrose before him had introduced the oriental choral chants into the western church of Italy. (See Music.) With regard to the tunes introduced into the early reformed church in the time of Luther and Calvin, some curious particulars are to be found in Bayle's *Dictionnaire Historique et Critique*, article Marot. The Puritans in England suppressed the church choral service, and permitted psalm-singing only. Charles II. revived the choral service in England. For minute accounts of the origin, progress, and revolutions of this species of music in various Christian churches, the reader may consult Gerbert, *De Cantu et Musica Sacra*, Padre Martini's *Storia*, Hawkins' and Burney's *Histories of Music*. For technicalities, &c., consult, among other works, A. E. Choron's *Méthode de Plain-Chant*, &c., Paris, 1818; and his *Principes pour apprendre le Plain-Chant*, Paris, 1818. (G. F. G.)

SERVITUDE, Penal. See Prison Discipline.

SERVIUS TULLIUS. See Roman History, § 4.

SESOSTRIS, or Rameses II. See Egypt.

SESSA, a town of the kingdom of Naples, province of Terra di Lavoro, on the western slope of the Massic Hills, on a small affluent of the Garigliano, 17 miles E. of Gaeta. It occupies the site of the ancient Suessa Aurunca, and is indeed built on the volcanic tufa which has covered the remains of that town; for an amphitheatre and some other buildings have been discovered beneath the town. The modern town is meanly built, but is the see of a bishop, and contains a cathedral, several other churches, convents, and charitable institutions. Some of the churches contain good pictures and monuments. Pop. 4000.

SESSION, Court of. See Scotland.

SESTERTIUS. See Coin.

SESTINI, Domenico, an eminent numismatist, naturalist, and traveller, was born at Florence about 1750. Having gained a solid grounding in classical learning, he entered upon the ecclesiastical profession, and in 1774 he became keeper of the cabinet of antiquities of Prince Biscari in Sicily. After holding this office for four years, he was appointed tutor to the Neapolitan ambassador at Constantinople, and was subsequently employed by Sir Robert Ainslie, the English ambassador, to collect medals for him. After various journeys taken from Constantinople, Sestini returned to Italy, where he published some six or seven works, mostly on his travels, and which were, for the most part, done into French. He subsequently visited the Levant, Salonichi, Tuscany, Germany, Paris, Florence, and Pisa. He resided, sometimes years, and sometimes only a few months, at those places. He was appointed honorary professor in the University of Pisa in 1814, and afterwards repaired to Hungary, where he was employed to arrange and catalogue the rich collection of coins and medals in the possession of Count Wiczay at Herderwar. Leopold II. subsequently chose Sestini to the office of royal antiquarian, and after his death, which occurred at Florence in 1832, he purchased his library and manuscripts, and among others, the work of his life in 14 vols. folio, the *Sistéma Numismatico*. Sestini wrote a great many works on his favourite branch of archæology, which will be found, with a biography of the author, in the *Antologia* of Florence for July 1832.

SETTLE, a market town of England, in the West Riding of Yorkshire, near the left bank of the Ribble, at the foot of a lofty limestone rock called Castleberg, rising in the midst of a fertile valley 54 miles W.N.W. of York. It is substantially built, and has one principal, and several smaller streets, and a market-place, in which stands a fine Elizabethan edifice for public purposes. The parish church stands on the other side of the river; but there is another established place of worship in the town, besides those belonging to the Wesleyan and Primitive Methodists, Independents, and Quakers. Settle contains cotton factories, worked by water-power, ropeworks, and paper-mills. Weekly markets and annual fairs are held here. Pop. 1976.

SETTLE, Elkanah, an English poet, who owes his reputation entirely to the ridicule which Dryden and Pope have heaped upon him, was born at Dunstable in 1648. He entered Trinity College, Cambridge, as a commoner, in 1666, where, although passing the university without a degree, he seems to have gained some sort of notoriety as a versifier. Dennis, Welstead, and Milbourn combine in placing Settle above Dryden during his college days; but the notoriety gained by youth is not always an earnest of after fame. Settle came up to London as a literary adventurer, and what with his university repute and the patronage of the profligate Rochester, he succeeded for a time in lording it over Dryden, who had then just entered upon his literary career. *Cambyses*, a tragedy, did not lower his reputation in the eyes of his professed admirers. His *Empress of Morocco*, printed in a style of unparalleled splendour, was acted by the lords and ladies of Whitehall, was applauded for a month at the theatre, and was sold at double its published price. The foolish author, quite intoxicated by his success, triumphantly ran a-muck of Dryden in a vaunting preface. Dryden, who could ill brook the taunts of an upstart adventurer, combined with Shadwell and Crowe in writing scurrilous notes to the *Empress*. The indignant author answered them after his fashion; but his fame had unfortunately now reached its culmination. He published a lame burlesque of Dryden's *Absalom and Achitophel*, entitled *Absalom Senior, or Absalom and Achitophel Transposed*, which had the effect of rousing the fierce wrath of the great poet, who, in the second part of his *Absalom and Achitophel*, impaled Settle and Shadwell under the names of Doeg and Og, and has rendered them quite an unenviable immortality.

> "Who by my muse to all succeeding times,
> Shall live, in spite of their own doggrel rhymes."

He satirizes, as only Dryden could, Settle's blundering

melody, his rude bombast, and his poverty of thought, and has left what, after all allowance has been made for the essential spirit of unfairness in which the poem is conceived, will be regarded by all readers as one of the most amusing pieces of poetical criticism on record. Pope has likewise once and again stumbled on poor unfortunate Settle in his *Dunciad* (Books i., 90, 146; iii., 37, 283), where he alludes in the most caustic terms to his glory as city poet and as Whig pamphleteer to Shaftesbury. Settle had the gratification of burning the Pope in effigy, to the no small delight of the London mob, in November 17, 1680; but afterwards he suddenly changed his party, and recanted his political heresies in 1683. The revolution extinguished him for ever, and he was compelled, as Dryden mockingly prophesied of him, to aspire to become "the master of a puppet-show." He kept a booth at Bartholomew fair, where in his old age he is said to have played the part of the dragon in green leather, in *St George for England*, with great effect! He was subsequently taken into the Charterhouse, where he died in 1723.

SETUBAL, erroneously called by the English St Elbes, a town of Portugal, in the province of Estremadura, on the north shore of a bay of the same name, 20 miles S.E. of Lisbon. It is encircled by old ruinous walls, and the whole valley in which it stands is commanded by several heights, which are crowned with forts. The town extends along the shore for about three-quarters of a mile, and consists for the most part of narrow crooked streets, extending parallel to the shore, or at right angles to it. There are several squares adorned with fountains. The houses are in general substantially built; and the most conspicuous edifices are four churches, some of which contain good paintings. There are two upper schools, and two hospitals, one of which occupies a handsome building. The harbour is large, deep, and furnished with commodious quays; but its entrance is obstructed by sand-banks. Large quantities of salt are made in the vicinity of Setubal, and exported to England, Sweden, and other countries. Corn, wine, and fruits are the chief other articles of trade. Setubal is an ancient town; and indeed, if we believe the Portuguese sages, was founded by Tubal, the grandson of Noah. There are many ancient remains in the vicinity, belonging probably to the ancient Cetobriga. After the expulsion of the Moors, Setubal was deserted for a long time; and it was only in the seventeenth century that it was fortified. The town suffered severely, along with Lisbon, from the earthquake of 1755. The people are extensively engaged in fishing. Pop. 15,201.

SEVAJEE. See HINDUSTAN.

SEVASTOPOL. See SEBASTOPOL.

SEVENOAKS, a market-town of England, in the county of Kent, on a hill 17 miles W. of Maidstone, and 23 S.S.E. of London. It is well built, and has two principal streets, which are wide, and contain many large houses. The parish church is a large edifice, chiefly in the perpendicular style, with a lofty tower. The other places of worship belong to Wesleyans and Baptists. There is a free grammar school, founded in 1418 by Sir William Sennocke, with two exhibitions to Cambridge, an endowed school, a range of almshouses, and a market-house. Near the town is Knole Park, a fine old mansion, in the midst of a magnificent park. Markets are held weekly at Sevenoaks, chiefly for corn. Pop. 1850.

SEVER, ST, a town of France, capital of an arrondissement in the department of Landes, in a fertile tract on the left bank of the Adour, 49 miles E.N.E. of Bayonne. This well-built place contains several fine edifices, among which are a magnificent church, a court-house, hospital, and barracks. It has a college, a court of law, tanneries, potteries, and oil mills. The chief articles of trade are corn, wine, brandy, and lithographic stones. Pop. (1856) 4679.

SEVERN, in point of length and importance, second to the Thames among British rivers; in the beauty and majesty of its aspect, surpassed by none. It rises at a place called Maes Hafren, in the moors, high up the eastern side of Plinlimmon, on the south-western border of Montgomeryshire. From that point its course is nearly semicircular to the sea, first towards the north-east, then southwards, and finally in a south-westerly direction to the Bristol Channel, which it enters at a point only 80 miles in a straight line S.E. of its source, though its length is about 200 miles. The counties it traverses are, in their order, Montgomeryshire, Shropshire, Worcestershire, and Gloucestershire. For the first 15 miles of its course the Severn flows over a rough precipitous bed, through a narrow valley, and is interrupted by many falls, some of which are of considerable size. At Llanidloes, the valley expands to the width of 1 or 2 miles, and assumes a more fertile and beautiful appearance. It is bounded on the S.E. by the range of the Plinlimmon Hills, and on the N.W. by the Berwyn Mountains. Its chief affluents here are the Clywedog and the Vyrnwy. From this gradually widening vale it emerges on the borders of Shropshire, and, turning to the S.E., enters the broad rich plain of Shrewsbury. With enlarged but gentle stream it flows beneath the dark castle and more modern towers of Shrewsbury; and skirted now by woods, now by meadows, it passes the western base of the Wrekin, and pursues its course through the county, receiving from the right the Meole, Cound, Mar Brook, and Bore Brook; and from the left the Perry Tern, Bell Brook, and Worf. Before leaving Shropshire, the river acquires a southerly direction, in which it continues to flow through Worcestershire. In this county it passes the towns of Stourport and Worcester, and, after entering Gloucestershire, those of Tewkesbury and Gloucester. From Buildwas under the Wrekin, to Gloucester, a distance of 72 miles, the fall of the river is only 104 feet; and from Stourport to Gloucester the breadth is very nearly the same, about 150 feet. Below the latter town, the breadth of the Severn, and the bold picturesque character of its banks, continually increase. Its course for some distance below Gloucester is very tortuous; but at Sharpness Point it expands very much, and, after a further course of 18 miles, the estuary of the Severn widens out into the Bristol Channel, just at the point where it receives from the left the Lower Avon or Bristol River; and from the right the Wye, which rises in Plinlimmon, close to its own source. From Gloucester downwards, the general course of the river is S.W. Besides the rivers already mentioned, the most important affluents of the Severn are the Teme from the right, the Upper Avon and the Frome from the left. In the lower part of its course, the Severn flows through a valley about 12 miles broad, bounded on the east by the Coteswold, and on the west by the Malvern Hills, neither of which rise to any great height. The whole extent of land drained by the Severn is 4500 square miles; and to this must be added 1400 drained by the Wye, making a total of 5900 square miles. Owing to the extent of this area, and the marly character of the greater part of it, the quantity of mud deposited in the estuary is greater than in that of any other river in Europe. The tide enters the estuary with great force; and the tidal wave or bore is here about 9 feet high. Inundations have frequently been caused by the sudden rise of the tide. At the mouth of the Severn it rises 48 feet, and at Chepstow, on the Wye, as high as 60 feet. The navigation of the Severn is of very great importance. It extends to 160 miles above its mouth, and affords to North Wales and the adjacent country the means of conveying their produce to the sea. Several canals connect it with the more important places in the adjacent parts of England. The Stroudwater Canal, and the Severn and Thames Canal, connect the waters of these two rivers; the Gloucester and Berkeley

Canal avoids the tedious windings of the Severn below the former town; and various other canals connect different parts of the river with Birmingham, Liverpool, and other towns. The Severn abounds in fish of many different kinds. The ancient name of the river was Hafren, by which it is still known above Llanidloes. It was called by the Romans Sabrina, a name it is said to have derived from a British princess who was drowned in it; and Milton has employed this name in his *Comus* to designate the goddess of the river.

SEVERUS. See Roman History, § 5.

SEVIGNÉ, Marie de Rabutin Chantal, Marquise de, was born in 1627. When only a year old she lost her father, who was killed in the descent of the English on the isle of Rhé, where he commanded a company of volunteers. In 1644 she married the Marquis of Sevigné, who was slain in a duel by the Chevalier d'Albret, in 1651. She had by him a son and a daughter, to the education of whom she afterwards religiously devoted herself. Her daughter was married in 1669 to the Count de Grignan, who conducted her to Provence. Madame de Sevigné consoled herself by writing frequent letters to her daughter, but she fell at last the victim to her maternal tenderness. In one of her visits to Grignan, she fatigued herself so much during the sickness of her daughter, that she was seized with a fever, which carried her off on the 14th of January 1696. We have two portraits of Madame de Sevigné; the one by the Comte de Bussi, and the other by Madame de la Fayette. Bussi describes her as a lively gay coquette, a lover of flattery, fond of titles, honour, and distinction; M. de la Fayette, as a woman of wit and good sense, as possessed of a noble spirit, formed for dispensing benefits, incapable of debasing herself by avarice, and blessed with a generous, obliging, and faithful heart. Both these portraits are in some measure just.

Madame de Sevigné was acquainted with all the wits of her age. It is said that she decided the famous dispute between Perrault and Boileau concerning the preference of the ancients to the moderns. She left behind her a most valuable collection of letters, a good edition of which is that of 1775, in eight volumes 12mo. "These letters," says Voltaire, "are filled with anecdotes, written with freedom, and in a natural and animated style; are an excellent criticism on studied letters of wit, and still more on those fictitious letters which aim at the epistolary style, by a recital of false sentiments and feigned adventures to an imaginary correspondent." It were to be wished that a proper selection had been made of these letters. They may be looked on as a relation of the manners, the tone, the genius, the fashions, and the etiquette, of the court of Louis XIV. They also contain many curious anecdotes nowhere else to be found. The most complete edition of these epistles is that of De Montmerqué, 13 vols., 1818, which contains many letters never before published. J. Ad. Aubenas has written the *Histoire de Madame de Sevigné de sa famille et de ses amis*, Paris, 1842; and Alphonse de Lamartine has written an elaborate account of her in his *Memoirs of Celebrated Characters*, Vol. III., 1856. A volume of *Sevigniana* was published at Paris in 1756.

SEVILLE (Sp. *Sevilla*), a province of Spain, Andalusia, bounded on the N. by the province of Badajoz, N.E. by that of Cordova, S.E. and S. by those of Malaga and Cadiz, and W. by that of Haelva. Area, 8011 square miles. It is in general a flat country, lying in the valley of the Guadalquiver, which traverses the province in a very irregular course from N.E. to S.W.; but near its northern and southern frontiers there are elevations of considerable height. In the north, Seville includes some of the highest summits of the Sierra Morena; and in the south, part of the Sierra of Ronda. Next to the Guadalquiver, the largest river in the province is its affluent the Jenil, which forms the boundary between Seville and Cordova. The Guadalquiver also receives from the right the Biar and the Cola; from the left the Corbones and the Guadaira, besides other streams of less importance. The mineral resources of the country are considerable. Coal is obtained in the Sierra Morena, marble and limestone in the Sierra of Ronda. Iron, silver, lead, and copper also exist in the province. The soil is extremely fertile, and produces in abundance all sorts of corn, wine, oil, vegetables, oranges, and other fruits. Tobacco, hemp, and flax are also grown. The climate is very warm and genial; the temperature in summer ranges from 90° to 100°, and in winter seldom descends lower than 48°; so that frost and snow are entirely unknown here. These rich and genial regions, which were made by the ancients the seat of the Elysian fields, have always offered a strong temptation to warlike tribes, and have been but feebly defended against their attacks by the indolent and peaceful natives of the soil. Manufactures are not carried on to any great extent here; the rich produce of the land sufficing to supply most of the necessaries and some of the luxuries of life. Silk fabrics are made in the capital; and in addition to this, coarse woollen cloth, linen, earthenware, cast-iron, soap, and brandy are manufactured in the province. Corn, oil, wool, fruits, and other articles are exported. The roads in this province, as in the whole of Andalusia, are very bad, being for the most part mere mule tracks. A railway has, however, been constructed from Cadiz to Cordova, which traverses the province; and the Guadalquiver is navigated by steamers as far as Seville. Pop. (1857) 501,050.

Seville, the capital of the above province, on the left bank of the Guadalquiver, 62 miles N.N.E. of Cadiz, and 242 S.W. of Madrid. It is circular in shape, about 5 miles in circumference, and surrounded with Moorish walls, which have 15 gates and 66 towers. The portion of the walls near the Cordova gate is one of the most perfect specimens of *ta pia*, a sort of hard concrete, formed of mortar, rubble, and stones. These walls, as well as what is called the golden tower, from having been the place of deposit for the treasures of America, are said to be of Roman origin; but their structure is undoubtedly Moorish. The only real Roman remains in the town are two pillars in the Alameda Vieja, some well-preserved *suggrundaria*, or underground tombs for infants, a subterranean aqueduct, and some fragmentary remains. Of Moorish antiquities there is no lack, for the town is indeed more than half Moorish. The streets are narrow and crooked, forming a labyrinth very difficult for the stranger to find his way through; and the houses have open courtyards, surrounded by corridors, and covered in summer with awnings. These narrow streets and spacious houses are very suitable to the hot weather in summer, as they afford some shelter and relief from the rays of the sun, which are very oppressive in the wide streets and small houses that have been erected in the more modern parts of the town. The Alameda Vieja was formerly the chief public walk of Seville; it is planted with elm-trees, and adorned with fountains and statues; but now the Paseo de Christina, and Las Delicias, a beautiful walk along the river-side, are more frequented. The streets of Sierpe and Francos are also very fashionable promenades; and the Plaza del Dugue is used for the same purpose in the summer moonlight nights. The chief other public squares are the Plaza de Toros, or bull-arena, which accommodates 14,000 spectators, and the Plaza de la Constitucion, which has a very picturesque appearance, with its Moorish arcades and balconies. The cathedral of Seville is one of the largest and grandest in Spain. It occupies the site of a former mosque, which was pulled down in 1480. The only portions that remain of the Moorish edifice are a horse-shoe gate, and the beautiful giralda or belfry, which was built in 1196. It was originally 250 feet high, and was the tower

 from which the Muezzin summoned the people to prayers; but in 1568 a very elegant belfry was added, raising the total height to 350 feet. A magnificent view is obtained from the summit, which is crowned by a vane, consisting of a bronze image of The Faith. The cathedral is of the same oblong form that the ancient mosque had; and its dimensions are—length, 431 feet; breadth, 315; height of the nave, 145 feet; of the *cimborio*, or transept dome, 171 feet. There are seven aisles, the two nearest the walls at each side being divided into chapels. At the west end of the central aisle is the tomb of Fernando, the son of Christopher Columbus; above which is erected, during Easter week, a large wooden chapel for the reception of the host. The painted windows of this cathedral are among the finest in Spain, mostly done by foreign artists in the 16th century. A rich Doric frontage, adorned with precious marbles, leads to the choir, and above it are two organs, one of which has 5300 pipes and 110 stops, being 50 more of the latter than that of Haarlem, and 20 more than that of Rotterdam. In the choir, the stalls, the archiepiscopal throne, and the carvings of the high altar are very fine. Behind the high altar is the Royal Chapel, which almost forms a church by itself. It is large and gloomy, and contains the tomb of Ferdinand III., who took the city from the Moors. Much superior to this chapel is the chapter-house, 50 feet long by 34 broad. Notwithstanding the repeated spoliations it has suffered, this cathedral is a magazine of the fine arts, and contains many of the masterpieces of Murillo and other great painters of the Seville school. Its general appearance is a gorgeous gloom, quiet and solemn; and when the rays of the sun fall on the cross above the high altar, it has a very fine effect. Besides the cathedral, Seville contained at one time about 140 churches; but many of these were destroyed or turned to other uses during the French invasion. There are now about 30 parish churches, some of which are very fine. Among those destroyed by the French were the Magdalena, in which Murillo was baptized; and Santa Cruz, where he was buried. His house is still preserved, containing the room in which he used to paint. Many also of the numerous convents that Seville possessed have been suppressed. Next to the cathedral, however, the most splendid building is the Alcasar, or royal palace, which has some Roman columns from the old prætorian palace on the same site. The principal hall, that of the ambassadors', in this palace is not inferior to that in the Alhambra; and the small chapel of Isabella is covered with some of the finest Moorish tiling in Spain. The University of Seville was founded in 1504, and transferred in 1767 to the Jesuits' convent, after their expulsion. It has one of the best collections of paintings in the town, and is usually attended by upwards of 1000 students. There are many other fine buildings in the town, such as the Lonja, or Exchange, in the classical style, the town-hall, court-house, the former mint, the archiepiscopal palace, the corporation house, and the Casa de Pilatos, a palace now belonging to the Duke de Medina Celi, built in the 15th century, it is said, after the model of Pilate's house in Jerusalem. There is a very good museum of paintings, an academy of the fine arts, two theatres, several colleges, a normal seminary, and numerous elementary schools. The number of benevolent institutions was at one time very great, there having been in 1558 no fewer than 76 hospitals; but many of these have since been suppressed. There are still, however, a considerable number, and some of them are very large and magnificent establishments. Seville contains two prisons and a house of correction, which are large and well managed. The largest manufactory in Seville is an enormous one of tobacco, outside the walls, occupying an area of 662 feet by 524. It has 28 interior courts, and employs no fewer than 4000 persons in the manufacture of cigars. Earthenware, crystal, machinery, soap, leather, cotton, linen, and silk fabrics, hats, &c., are also manufactured here. The manufactured articles are, however, of very inferior quality. Seville is said to have been formerly much more important as a manufacturing town than it is at present; and although many of the statements about its former prosperity are evidently and egregiously exaggerated, there is no reason to doubt that at one time it was an important seat of the silk manufacture. From about the middle of the seventeenth to the beginning of the present century, this branch of industry, with many fluctuations, continued to maintain a high position; but subsequently it has very much fallen off. The trade of the place, too, has declined from the period when it enjoyed a monopoly of the commerce with America, as the difficulty of navigating the river with large vessels caused Seville to be supplanted by the more convenient port of Cadiz. The chief articles exported are wool, leather, silk, oil, oranges, quicksilver, lead and copper; while the imports consist principally of iron, steel, hardware, timber, cloth, cheese, butter, &c. The total value of the imports in 1856 was, L.558,893; and of the exports, L.606,614. In the same year there entered the port 262 vessels; tonnage, 30,164: and there cleared 281; tonnage, 31,688. The first settlement that took place on the site of Seville was a Phœnician colony, under the name of Hispal, which has passed through the Hispalis of the Romans, and the Ishbiliah of the Moors, into the Sevilla of the modern Spaniards. Little is known of its history previous to the Roman conquest of the Peninsula. Julius Cæsar conquered it in 45 B.C., and patronized the town in opposition to Cordova, which had adhered to the cause of Pompey. It was, however, inferior in importance both to that town and to Gades, until the invasion of the Goths, who made it their capital; but in the sixth century the court was removed to the more central situation of Toledo. Seville opened its gates to the Moors in 711; and remained in their possession till 1247, when it was besieged by the Christians under Ferdinand III. of Castile and Leon. This siege, which issued in the capture of the city in the following year, is the most remarkable event by which the city has been distinguished. It was the capital of Spain from that period till the time of Charles V., who transferred that honour to Valladolid. In 1729 a treaty was concluded at Seville between England, France, and Spain. In 1810 it surrendered to the French under Soult, but was evacuated by them in 1812, after the battle of Salamanca. Many eminent men have been born in Seville or its vicinity. Among these are—the emperor Trajan; the philanthropic Las Casas; Rueda, the founder of Spanish comedy; Ulloa, the traveller; Murillo and Velasquez, the painters. Seville is, for size, the third city in Spain. Pop. (1857) 152,000.

SÈVRES, DEUX, a department of France, bounded on the N. by that of Maine-et-Loire, E. by that of Vienne, S. by those of Charente and Charente-Inférieure, and W. by that of Vendée. Its length, from N. to S., is about 79 miles; greatest breadth, 41; area, 2341 square miles. It is traversed by a chain of low hills, called the Hills of Gâtine, which extends from the mountains of Auvergne N.W. to the mouth of the Loire, entering the department from Vienne at the S.E., and leaving it at the N.W., on the borders of Vendée. Their mean height is not more than 450 feet; and they separate the valley of the Loire on the N.E. from those of the Charente, Sèvre Niortaise, and Lay, on the S.W. Neither the Loire nor the Charente traverse any part of the department, but they receive some considerable tributaries from it; the Loire receiving the Sèvre Nantaise flowing towards the N.W., and the Thouet with its tributaries the Cebron, Argenton, and Dive; and the Charente receiving the Boulonne. The Sèvre Niortaise receives the Mignon, which flows along the south-western boundary of the department. Of these rivers, three are

navigable for some distance, the Dive, the Sèvre Niortaise, and the Mignon. There are no considerable lakes in the country, but some ponds and marshes among the hills. The hills themselves are rugged and granitic, covered with wood, and traversed by numerous valleys. From these hills the ground descends on either side to extensive plains; those on the north having, like the hills generally, a granitic formation, while towards the south the prevailing structure of the country is calcareous. Thus, though the soil of the department is, on the whole, rich and fertile, it varies considerably in productiveness in different parts; the southern plain being in general superior to the northern. Agriculture is the chief employment of the people; but it is in a very backward state, few efforts being made to improve the soil. Corn and wine are the principal productions of the country; a considerable extent of ground is occupied by meadows and forests, chiefly on the slopes of the hills; hemp and flax grow in the more moist tracts; and hops are raised with success especially in the neighbourhood of Niort. Of the entire area of the department, there are calculated to be 1.010,000 acres of arable land; 185,000 of meadows; 50,000 of vineyards; 90,000 of wood; and 55,000 of heaths and waste land. The vineyards, which exist only in the south-west portion of the department, produce very good white wines, and excellent brandy. The extensive natural meadows of the country support cattle of good breeds, and sheep of a large size, which by a cross with the Spanish breed have been much improved in the quality of their wool; pigs, mules, and asses are also reared. It is estimated that the department contains 33,000 horses, 114,000 horned cattle, 426.000 sheep, 42,000 pigs, 20,000 goats, 13,000 mules, and 4000 asses. The mineral productions of the country are not of very great importance. Small quantities of iron, marble, mill-stones, chalk, potter's clay, and saltpetre, are the only minerals that are worked. Among the manufactories are those of woollen and cotton stuffs; of leather at Niort; besides distilleries, potteries, oil-mills, &c. The principal articles of trade are live stock; especially mules, which are sent in large numbers to Spain, and cattle which are sent either to Normandy to be fattened, or to Paris. Corn, wine, and brandy are also among the articles of commerce. Internal communication is facilitated by the navigable rivers, by numerous roads, and by a railway which traverses the southern part of the country. Deux Sèvres forms, along with Vienne, the diocese of the Bishop of Poitiers, and contains 5 Calvinist churches. It has 5 courts of law, subordinate to the appeal court at Poitiers, a tribunal of commerce, 4 colleges, a normal seminary, 2 superior and 527 elementary schools. The department has for its capital Niort, and is divided into four arrondissements, as follows:—

	Cantons.	Communes.	Pop. 1856.
Niort	10	93	108,160
Bressuire	6	91	71,192
Melle	7	91	77,384
Parthenay	8	79	71,110
Total	31	354	327,846

Sèvres, a town of France, department of Seine-et-Oise, on the left bank of the Seine, between the hills of Mendon and St Cloud, 6 miles N.W. of Paris. It is chiefly remarkable for the manufacture of the fine porcelain that takes its name from the town. The manufactory was removed from Vincennes to the present large building, in 1755, when it was purchased by Louis XV. It is now the property of the nation. There is here a large museum of porcelain, containing specimens of all ages and countries. Sèvres is also remarkable for the colouring of the china; and has manufactures of colour, enamel, and painted glass. Pop. 4891.

SEWESTAN, a tract of land in Afghanistan, forming the south-eastern corner of that country, lying between N. lat. 29° 30′ and 30° 30′; about E. long. 69° 30′. It forms part of the Khanat of Candahar. On the east it is separated by the Suliman Mountains from the Punjab; on the south from Beloochistan by the mountains about Kohun; on the west it is inclosed by the Toba and Hala ranges; and towards the north it has no definite limit. It consists of a flat dry clayey plain, whose excessive heat is only alleviated by the streams that flow in some places from the hills. The chief town is Sewee, or Sebee, near the southern frontier, in a tract of land which is one of the best cultivated parts of the country.

SEXAGESIMA, the second Sunday before Lent, or the next to Shrove Sunday; so called as being about the sixtieth day before Easter.

SEXAGESIMALS, or Sexagesimal Fractions, are such as have 60, or some multiple of 60, for their denominator. The denominator being usually omitted, 4°, 59′, 32″, 50‴, 16⁗, is to be read, 4 degrees, 59 minutes, 32 seconds, 50 thirds, and 16 fourths.

SEXTANT, denotes the sixth part of a circle, or an arch comprehending sixty degrees. The word sextant is more particularly used for an astronomical instrument made like a quadrant, excepting that its limb only comprehends sixty degrees. (See Quadrant and Mural Circle.)

SEXTUS EMPIRICUS, the celebrated author of the *Pyrrhonian Hypotyposes*, was a physician who attached himself to the school of the Empirici, and hence the name by which he is usually known. He was a pupil of Herodotus of Tarsus (Diog. Laërt. ix. *Timon*), who was himself a physician, and most probably a contemporary of Galen. This serves to settle, with some degree of accuracy, the era of Sextus, who must have flourished about the first half of the third century after Christ. Nothing whatever is known of his life. He has given full proof to all succeeding thinkers in the two books which he has left behind him, of the precise complexion of his creed, and the amount of ingenuity with which he was capable of defending it. The first work, Πυῤῥώνιαι Ὑποτύπωσεις ἢ σκεπτικὰ ὑπομνήματα, contains a complete repository of the doctrines of the sceptics. His second work, Πρὸς τοὺς μαθηματικοὺς ἀντιῤῥητικοί, in eleven books, is against the mathematicians, or dogmatists, and attempts to refute every vestige of positive knowledge which man has ever elaborated. The works combined form the most correct account extant of the ancient sceptical thinkers, and their mode of assailing all manner of dogmatism. It is a perfect store-house of doubts regarding every imaginable phasis of human knowledge. It is set forth with eminent clearness, and contains an exposition of the doctrines maintained by the sceptical school. Sextus now and then degenerates into pure logomachy, a thing to be expected, but with this exception, it is really wonderful the amount of acute pertinacious pursuit with which every idea, real or supposed, is hunted down and strained into the sceptical alembic. He enunciates at the outset what he understands by scepticism. It is, he says, a disposition to doubt of everything beyond mere phenomena. Sextus carries out this definition with the most rigid exactness. It is, without doubt, one of the most refreshing books that a man of reflection can meet with, and it is really surprising to find that the same everlasting problems, which, sixteen centuries ago, were perplexing the minds of thinking men, are still occupying the attention and exciting the passions of philosophers, and apparently will do so to the very end. For an account of the tenets of this author see Scepticism. The *Editio Princeps* of the Greek text of Sextus was that of Paris and Geneva, 1621. The second impression of the works of Sextus Empiricus was by J. A. Fabricius, Leipzig, 1718. A good edition of the Greek text is that of Bekker, Berlin, 1842. The first Latin translation of the *Hypo-*

typoses was published by H. Stephens, in 1562. The first Latin version of the work against the Dogmatists is by G. Hervet, Antwerp and Paris, 1569. Buhle translated the *Hypotyposes*, or outlines, in 1801; and there is an anonymous French version, or rather paraphrase, of them, supposed to be by one Huart, a teacher of mathematics, published in 1725. An English version of the works of Sextus is still a desideratum; but the text would require considerable purification before a respectable translation could be executed. None of the medical works of Sextus remain.

SEYCHELLES, a group of islands in the Indian Ocean, lying between S. Lat. 3. 33. and 5. 35., E. Long. 55. 15. and 56. 10.; 915 miles N. of Mauritius, 566 N.E. of Madagascar, and 1470 S.W. of the continent of India. They are 29 in number, but most of them are of very small size, being merely rocks rather than islands. They stand on a bank of coral and sand, rising from the depths of the ocean to a distance varying from 12 to 40 fathoms from its surface. This bank stretches from north to south for a distance of about 200 miles, and from east to west 30 or 40 miles. The islands themselves, with the exception of two of coralline structure, are granitic, and have a very rugged and irregular appearance, rising into peaks in the centre, which are not cultivated, but covered with perpetual verdure. The soil is good, and the climate warm and equable; hurricanes and violent gales are unknown. Sugar canes, tobacco of excellent quality, cloves, and many kinds of trees, among which is the *coco de mer*, or Seychelles cocoa-nut, peculiar to these islands, grow luxuriantly. Cotton is also raised, and an active trade is carried on in it; but though of excellent quality, it has not yet come into competition with that of the United States. Turtles abound in the islands, and the sperm whale is frequently met with at no great distance. The people are much given to seafaring pursuits, and there is a great want of agricultural labourers. Mahé, the the largest of the islands, is about 17 miles long by 4 broad, and rises to the height of 2000 feet. It is well wooded, and watered by many rivulets. The scenery is very picturesque, and the soil varied, but fertile. On its east coast is a fine bay called Port Victoria, 4 miles deep by 3½ wide, and capable of accommodating a large number of vessels. Next in size to the island of Mahé are those of Praslin, Silhouette, Digue, and Curieuse. The Seychelles are a dependency of Mauritius, and are under a civil commissioner, subject to the government of that island. The public expenditure for 1855 amounted to L.4090, while the revenue was little more than half that sum; the total revenue for the three years 1853–4–5 being L.6495. Education is in a backward state, and there were only forty-nine children attending school in 1855. Most of the inhabitants are Roman Catholics; and indeed there is no Protestant church in the islands, though a chaplain of that religion officiates in Mahé. The Seychelles were first discovered by Vasco di Gama in 1502; but it was not till 1742 that they were explored by Captain Picault, who took possession of them in the name of the King of France, and called them after the French marine minister at that time. They were captured by the British in 1794, and ceded to them along with Mauritius by the treaty of 1815. The population in 1856 of the Seychelles, including the other dependencies of Mauritius, was 8007.

SEYNE, a seaport of France, in the department of Var, on the Mediterranean, 3 miles S.W. of Toulon, at the west end of the inner roadstead of that town. It is regularly laid out and well built, and has spacious quays, a good harbour, and a shipbuilding-yard. Many of the inhabitants are employed in tunny and sardine fisheries, and there is a considerable coasting trade. Pop. 4582.

SÉZANNE, a town of France, in the department of Marne, on the slope of a hill, 25 miles S.W. of Epernay. It was formerly fortified, and the site of its defences is now occupied with fine boulevards. There is a curious old church, with painted glass in the windows. Flour, oil, vinegar, leather, coarse cloth, tiles, and earthenware are made here; and there is some trade in honey and wax. Pop. 4453.

SEZZA, or SEZZE (anc. *Setia*), a town of the Papal States, in the province and 18 miles S.W. of Frosinone. The place was anciently celebrated for its wine, but this is not now above mediocrity. Here are the remains of an old temple of Saturn, and of the Cyclopean fortifications of the town. Figs and other fruits are grown in the neighbourhood. Pop. 8650.

SFAX, or SFAKUS, a town of Tunis, on the west shore of the Gulf of Cabes, 70 miles N.N.E. of Cabes. N. Lat. 34. 44., E. Long. 10. 40. It stands in a very fertile region; and outside the walls by which it is surrounded, lie beautiful gardens. Most of the houses are well built, and there is one large mosque, besides others of smaller size. There are important manufactories of woollen cloth and mats in the town; and an active trade is carried on in fruits, soap, wax, and wool. Sfax is a place of resort for the caravans that come from Gadames in the Sahara. The harbour is very much choked up with mud. As none but natives are allowed to live in the town, there are many dwellings outside the walls. Pop. 6000.

SFORZA. See ITALY.

'SGRAVESANDE. See GRAVESANDE.

SHADWELL, THOMAS, a dramatic writer, well known as the hero of Dryden's satire of *MacFlecknoe*, was born in Norfolk in 1640 of an ancient Staffordshire family. He was educated at Caius College, Cambridge, and subsequently went to study law at the Inner Temple. Disgusted with the drudgery attendant upon legal pursuits, he quitted law and London together, and spent some time in foreign travel. Returning to England, he betook himself to writing for the stage, and gained considerable reputation among the reigning wits of the time, of whom the chief were Dryden, Otway, and Rochester, as a smart, witty talker, but he was pronounced much too hasty a writer. Shadwell, who was a large, round, unwieldy man, set up as a second Ben Jonson, and in eating and drinking he must be confessed to have rivalled his master, but came very far short of him in genius. He rose to be poet-laureate and historiographer to the king on the retirement of Dryden in 1688, and was one of the most important writers of the Whig party. Dryden, who had formerly been his friend, has immortalized him in perhaps the keenest personal satire in the English language. Conceived, as the *MacFlecknoe* is, in a thoroughly satirical spirit, of course all hope of fairness is at once banished from the mind on reading the first line of it. Yet with such immense gusto does the poet bring all the resources of his wonderful art to crush his opponent, and with such singular relish does he heap upon him the most unmeasured contempt, that one cannot help excusing the satirist while one laughs hugely at *MacFlecknoe*. Dryden has been often blamed for the untruthfulness of his representation; he should have been blamed rather for being a satirist. Not satisfied with the bruising which Shadwell had received in the *MacFlecknoe*, Dryden has drawn another immortal portrait of him on his way home from a treason-tavern—

> "Round as a globe, and liquored every chink,
> Goodly and great, he sails behind his link;"

in the second part of his *Absalom and Achitophel*. Shadwell did not escape the bitter mockery of Pope in his *Dunciad*. The great defect of Shadwell in dramatic composition seems to have been his precipitation. Rochester, who, with all his faults, must be allowed the character of great penetration, has left a much more flattering delineation of this much maligned poet than any that has yet been given of him. His Lordship says he had unquestionable genius, but his artistic

skill was below mediocrity. This nobleman further adds:—"If Shadwell had burnt all he wrote, and printed all he spoke, he would have had more wit and humour than any other poet." Shadwell died in 1692 in consequence of too large a dose of opium, which he is reported to have been in the habit of taking.

A complete edition of Shadwell's works was published in 1720, in 4 vols. 12mo. His dramatic works are:—*The Sullen Lovers*, 1668; *The Royal Shepherdess*, 1669; *The Humorist*, 1671; *The Miser*, 1672; *Epsom Wells*, 1673; *Psyche*, 1675; *The Libertine*, 1676; *The Virtuoso*, 1676; *Timon of Athens*, 1678; *A True Widow*, 1679; *The Woman Captain*, 1680; *The Lancashire Witches*, 1682; *The Squire of Alsatia*, 1688; *Bury Fair*, 1689; *The Amorous Bigot*, 1690; *The Scowerers*, 1691; and *The Volunteers*, 1693.

SHAFTESBURY, Earl of. See Cooper.

SHAFTESBURY, a market-town, municipal, and parliamentary borough of England, in Dorsetshire, on the summit of a high, narrow hill, commanding a fine view over the fertile country which stretches at its foot, 22 miles N.E. of Dorchester, and 95 S.W. of London. On account of its lofty and exposed situation, it has a cold, bleak, but healthy atmosphere. Irregularly laid out, the houses are for the most part well built of the freestone quarried in the vicinity. Of the places of worship in the town, four belong to the Established Church: St Peter's, near the centre of the town, an ancient edifice, but modernized for the worse; Trinity Church, in the midst of the lime-trees of its spacious churchyard; St James'; and Rombald's. The Independents, Wesleyans, and Quakers have also places of worship here. The town-hall is a handsome building, recently erected by the Marquis of Westminster. There is an endowed blue coat school in the town, national and other schools, a reading-room, savings' bank, and some charitable institutions. The manufacture of buttons was formerly carried on at Shaftesbury, but has entirely fallen off. Some trade is carried on in butter and cheese, as well as in the agricultural produce of the fine land round about. Weekly markets and three annual fairs are held. The borough is governed by a mayor, three other aldermen and eighteen councillors; and it returns one member to Parliament. The modern town is supposed to occupy the site of the place called Caersepton by the ancient Britons. It was a Roman station, but attained to no great importance till the foundation of the celebrated abbey here by Alfred about 888. Both before and after this time it was destroyed by the Danes, but each time it was afterwards restored. It is said to have contained at the time of the Norman conquest 166 houses and 12 churches. In the abbey of Shaftesbury, Canute died in 1035, and Elizabeth, the wife of King Robert the Bruce of Scotland, was confined for some time in 1313. The family of Ashley Cooper take the title of earl from the town of Shaftesbury. It was first conferred by Charles II. in 1672 on his favourite statesman. Pop. (1851) of the municipal borough, 2503; of the parliamentary borough, 9404.

SHAHABAD, a district of British India, Bengal, lying between N. Lat. 24. 30. and 25. 46.; E. Long. 83. 20. and 84. 56.; bounded on the N. by the districts of Ghazeepoor and Sarun, E. by that of Patna, S.E. and S. by that of Behar, and W. by those of Mirzapore and Benares. Length from N.E. to S.W. 106 miles; breadth 56; area, 4403 square miles. It is almost entirely inclosed by natural boundaries, formed by the Ganges on the N., the Carumnassa on the W., and the Sone on the S.E. and E. The last two rivers both fall into the Ganges, which, as well as the Sone, is navigable here. The south-western part of the district is occupied by a hilly country, rising to the height of about 700 feet above the sea, and about 500 above the low lands on the banks of the Ganges. This latter portion consists of an extensive plain, liable to annual inundations of the Ganges. Most of the land is arable; and the soil is either sandy or clayey, producing, without irrigation, wheat, barley, and some other crops; while the northern portions of the country are rendered exceedingly rich by the overflowing of the river, and are planted chiefly with rice, which produces two crops a year. Maize, millet, lentils, beans, and various other plants are also grown. The chief commercial crops are sugar, cotton, opium, indigo, and tobacco. A large portion of the country is covered with wood and jungle; but the trees are generally stunted, and yield little good timber. Cotton cloth, silk, paper, spirits, oil, and sugar are manufactured. The chief exports are silk, paper, cotton, wheat, and other grains, pulse, bamboos, and opium; the imports include tobacco, sugar, iron, copper, lead, tin, zinc, salt, &c. Shahabad is traversed by the route from Calcutta to Allahabad, and also by that from Dinapoor to Ghazeepoor. The country at one time formed part of the great Magadha empire; but came into the power of the sultans of Lahore towards the close of the twelfth century. The southern part of the district was ceded to the British by the Emperor of Delhi in 1765, and the northern part by the Vizier of Oude in 1775. Pop. 1,600.000.

SHAH ADDULAZIM, a village of Persia, in the province of Irak Ajemi, 5 miles S.E. of Teheran. It is famous as the birth-place of the Caliph Harunur-rashid, and also for a noble mosque which it contains; and still more renowned as occupying the site of the ancient Rhagae, now Rhe, the capital of Arsaces, and the birth-place of Hasan Sabah, the prince of the Assassins, called the "Old Man of the Mountain," who founded the sect of the Ismaelians. The sepulchre of Togral Beg, the Seljuk prince, who conquered Persia in the eleventh century, stands beside the village near the hills. It is a large polygonal brick tower.

SHAHJEHANPORE, a district of British India, N.W. provinces, lying between N. Lat. 27. 15. and 28. 45.; E. Long. 79. 23., and 80. 30.; having Oude on the E., and the districts of Budaon and Bareilly on the W., that of Pilleebheet on the N., and Furruckabad on the S. Its shape is irregular, somewhat like a crescent concave to the west; and its area is 2483 square miles. The country has a general slope downwards from N.W. to S.E.; and in this direction the principal rivers flow. The Gogra washes its north-eastern, and the Ganges its south-western frontier for a short distance. Between these flow the Goomtee, Gurrah, Ramgunga, and others of smaller size. All these rivers ultimately flow into the Ganges. The most elevated portion of the district is in the extreme north, and attains a height of 798 feet above the sea, the bed of the Ganges is about 500 feet above the sea. In the north a large part of the land is occupied by the marshy forests and jungles that lie at the base of the sub-Himalaya range. Gigantic trees, interspersed with thick underwood or tall herbage, cover the land, and a deadly malaria has emptied these forests of men and domestic animals; the elephant, rhinoceros, tiger, panther, and other wild animals roam undisturbed. This country is only useful for a short season for pasturage, and for the production of timber. The southern part of Shahjehanpore enjoys a healthy climate, and a soil rich, well wooded, and highly cultivated. Wheat, rice, maize, cotton, sugar, tobacco, pulse, and many kinds of fruit are grown. The people are generally employed in agriculture, in which they are skilful and industrious. About three-fourths of them are Hindoos, and the rest Mohammedans. Shahjehanpore formed part of the dominions of the Rohilla Patans until their total defeat and overthrow by the British in 1774. It was then transferred to the vizier of Oude, and finally ceded to the East India Company in 1801. Pop. (1848) 812,588. The chief town is Shahjehanpore, on the left bank of the Garrah. It is large and generally well built, and contains a castle, and several stately old mosques, all in a ruinous condition. The bazaars are well stocked and frequented. Pop. 62,785.

SHAKSPEARE.[1]

Shakspeare.

Shakspeare.

William Shakspeare, the protagonist on the great arena of modern poetry, and the glory of the human intellect, was born at Stratford-upon-Avon, in the county of Warwick, in the year 1564, and upon some day, not precisely ascertained, in the month of April. It is certain that he was baptized on the 26th; and from that fact, combined with some shadow of a tradition, Malone has inferred that he was born on the 23d. There is doubtless, on the one hand, no absolute necessity deducible from law or custom, as either operated in those times, which obliges us to adopt such a conclusion; for children might be baptized, and were baptized. at various distances from their birth: yet, on the other hand, the 23d is as likely to have been the day as any other; and more likely than any earlier day, upon two arguments. First, because there was probably a tradition floating in the seventeenth century, that Shakspeare died upon his birth-day: now it is beyond a doubt that he died upon the 23d of April. Secondly, because it is a reasonable presumption, that no parents, living in a simple community, tenderly alive to the pieties of household duty, and in an age still clinging reverentially to the ceremonial ordinances of religion, would much delay the adoption of their child into the great family of Christ. Considering the extreme frailty of an infant's life during its two earliest years, to delay would often be to disinherit the child of its Christian privileges; privileges not the less eloquent to the feelings from being profoundly mysterious, and, in the English church, forced not only upon the attention, but even upon the eye, of the most thoughtless. According to the discipline of the English church, the unbaptized are buried with "maimed rites," shorn of their obsequies, and sternly denied that "sweet and solemn farewell" by which otherwise the church expresses her final charity with all men; and not only so, but they are even *locally* separated and sequestrated. Ground the most hallowed, and populous with Christian burials of households,

> That died in peace with one another,
> Father, sister, son, and brother.

opens to receive the vilest malefactor; by which the church symbolically expresses her maternal willingness to gather back into her fold those even of her flock who have strayed from her by the most memorable aberrations; and yet, with all this indulgence, she banishes to unhallowed ground the innocent bodies of the unbaptized. To them and to suicides she turns a face of wrath. With this gloomy fact offered to the very external senses, it is difficult to suppose that any parents would risk their own reproaches by putting the fulfilment of so grave a duty on the hazard of a convulsion fit. The case of royal children is different; their baptisms, it is true, were often delayed for weeks; but the household chaplains of the palace were always at hand, night and day, to baptize them in the very agonies of death.[2] We must presume, therefore, that William Shakspeare was born on some day very little anterior to that of his baptism; and the more so because the season of the year was lovely and genial, the 23d of April in 1564 corresponding in fact with what we now call the 3d of May, so that, whether the child was to be carried abroad, or the clergyman to be summoned, no hindrance would arise from the weather. One only argument has sometimes struck us for supposing that the 22d might be the day, and not the 23d; which is, that Shakspeare's sole grand-daughter, Lady Barnard, was married on the 22d of April 1626, ten years exactly from the poet's death; and the reason for choosing this day *might* have had a reference to her illustrious grandfather's birthday; which, there is good reason for thinking, would be celebrated as a festival in the family for generations. Still this choice *may* have been an accident, or governed merely by reason of convenience. And, on the whole, it is as well perhaps to acquiesce in the old belief, that Shakspeare was born and died on the 23d of April. We cannot do wrong if we drink to his memory on both 22d and 23d.

On a first review of the circumstances, we have reason to feel no little perplexity in finding the materials for a life of this transcendent writer so meagre and so few; and amongst them the larger part of doubtful authority. All the energy of curiosity directed upon this subject, through a period of one hundred and fifty years (for so long it is since Betterton the actor began to make researches) has availed us little or nothing. Neither the local traditions of his provincial birth-place, though sharing with London through half

---

[1] Mr Campbell, in his edition of Shakspeare's dramatic works, observes that "the poet's name has been variously written Shaxpeare, Shackspeare. Shakspeare, and Shakspere;" to which varieties might be added Shagspere, from the Worcester Marriage License, published in 1836. But the fact is, that by combining with all the differences in spelling the first syllable, all those in spelling the second, more than twenty-five distinct varieties of the name may be expanded (like an algebraic series), for the choice of the curious in mis-spelling. Above all things, those varieties which arise from the intercalation of the middle *e* (that is, the *e* immediately before the final syllable *spear*), can never be overlooked by those who remember, at the opening of the Dunciad, the note upon this very question about the orthography of Shakspeare's name, as also upon the other great question about the title of the immortal Satire, Whether it ought not to have been the Dunceiade, seeing that Dunce, its great author and progenitor, cannot possibly dispense with the letter *e*. Meantime we must remark, that the first three of Mr Campbell's variations are mere caprices of the press; as is Shagspere; or, more probably, this last euphonious variety arose out of the gross clownish pronunciation of the two hiccuping "*marksmen*" who rode over to Worcester for the license; and one cannot forbear laughing at the bishop's secretary for having been so misled by two varlets, professedly incapable of signing their own names. The same drunken villains had cut down the bride's name *Hathaway* into *Hathwey*. Finally, to treat the matter with seriousness, Sir Frederick Madden has shown, in his recent letter to the Society of Antiquaries, that the poet himself in all probability wrote the name uniformly *Shakspere*. Orthography, both of proper names, of appellatives, and of words universally, was very unsettled up to a period long subsequent to that of Shakspeare. Still it must usually have happened that names written variously and laxly by others, would be written uniformly by the owners; especially by those owners who had occasion to sign their names frequently, and by literary people, whose attention was often, as well as consciously, directed to the proprieties of spelling. *Shakspeare* is now too familiar to the eye for any alteration to be attempted; but it is pretty certain that Sir Frederick Madden is right in stating the poet's own signature to have been uniformly *Shakspere*. It is so written twice in the course of his will, and it is so written on a blank leaf of Florio's English translation of Montaigne's Essays; a book recently discovered, and sold, on account of its autograph, for a hundred guineas.

[2] But, as a proof that, even in the case of royal christenings, it was not thought pious to "tempt God," as it were, by delay, Edward VI. the only son of Henry VIII. was born on the 12th day of October in the year 1537. And there was a delay on account of the sponsors, since the birth was not in London. Yet how little that delay was made, may be seen by this fact: The birth took place in the dead of the night, the day was Friday; and yet, in spite of all delay, the christening was most pompously celebrated on the succeeding Monday. And Prince Arthur, the elder brother of Henry VIII. was christened on the very next Sunday succeeding to his birth, notwithstanding an inevitable delay, occasioned by the distance of Lord Oxford, his godfather, and the excessive rains, which prevented the earl being reached by couriers, or himself reaching Winchester, without extraordinary exertions.

a century the honour of his familiar presence, nor the recollections of that brilliant literary circle with whom he lived in the metropolis, have yielded much more than such an outline of his history as is oftentimes to be gathered from the penurious records of a grave-stone. That he lived, and that he died, and that he was " a little lower than the angels ;"—these make up pretty nearly the amount of our undisputed report. It may be doubted indeed whether at this day we are as accurately acquainted with the life of Shakspeare as with that of Chaucer, though divided from each other by an interval of two centuries, and (what should have been more effectual towards oblivion) by the wars of the two roses. And yet the traditional memory of a rural and a sylvan region, such as Warwickshire at that time was, is usually exact as well as tenacious ; and, with respect to Shakspeare in particular, we may presume it to have been full and circumstantial through the generation succeeding to his own, not only from the curiosity, and perhaps something of a scandalous interest, which would pursue the motions of one living so large a part of his life at a distance from his wife, but also from the final reverence and honour which would settle upon the memory of a poet so pre-eminently successful; of one who, in a space of five-and-twenty years, after running a bright career in the capital city of his native land, and challenging notice from the throne, had retired with an ample fortune, created by his personal efforts, and by labours purely intellectual.

How are we to account, then, for that deluge, as if from Lethe, which has swept away so entirely the traditional memorials of one so illustrious? Such is the fatality of error which overclouds every question connected with Shakspeare, that two of his principal critics, Steevens and Malone, have endeavoured to solve the difficulty by cutting it with a falsehood. They deny in effect that he *was* illustrious in the century succeeding to his own, however much he has since become so. We shall first produce their statements in their own words, and we shall then briefly review them.

Steevens delivers *his* opinion in the following terms :—" How little Shakspeare was once read, may be understood from Tate, who, in his dedication to the altered play of King Lear, speaks of the original as an obscure piece, recommended to his notice by a friend ; and the author of the Tatler, having occasion to quote a few lines out of Macbeth, was content to receive them from Davenant's alteration of that celebrated drama, in which almost every original beauty is either awkwardly disguised or arbitrarily omitted." Another critic, who cites this passage from Steevens, pursues the hypothesis as follows :—" In fifty years after his death, Dryden mentions that he was then become *a little obsolete*. In the beginning of the last century, Lord Shaftesbury complains of his *rude unpolished style, and his antiquated phrase and wit*. It is certain that, for nearly a hundred years after his death, partly owing to the immediate revolution and rebellion, and partly to the licentious taste encouraged in Charles II.'s time, and perhaps partly to the incorrect state of his works, he was ALMOST ENTIRELY NEGLECTED." This critic then goes on to quote with approbation the opinion of Malone,—" that if he had been read, admired, studied, and imitated, in the same degree as he is now, the enthusiasm of some one or other of his admirers in the last age would have induced him to make some inquiries concerning the history of his theatrical career, and the anecdotes of his private life." After which this enlightened writer re-affirms and clenches the judgment he has quoted by saying,—" His admirers, however, *if he had admirers in that age*, possessed no portion of such enthusiasm."

It may perhaps be an instructive lesson to young readers, if we now show them, by a short sifting of these confident dogmatists, how easy it is for a careless or a half-read man to circulate the most absolute falsehoods under the semblance of truth ; falsehoods which impose upon himself as much as they do upon others. We believe that not one word or illustration is uttered in the sentences cited from these three critics, which is not *virtually* in the very teeth of the truth.

To begin with Mr Nahum Tate:—This poor grub of literature, if he did really speak of Lear as " an *obscure* piece, recommended to his notice by a friend," of which we must be allowed to doubt, was then uttering a conscious falsehood. It happens that Lear was one of the few Shakspearian dramas which had kept the stage unaltered. But it is easy to see a mercenary motive in such an artifice as this. Mr Nahum Tate is not of a class of whom it can be safe to say that they are " well known :" they and their desperate tricks are essentially obscure, and good reason he has to exult in the felicity of such obscurity ; for else this same vilest of travesties, Mr Nahum's Lear, would consecrate his name to everlasting scorn. For himself, he belonged to the age of Dryden rather than of Pope : he " flourished," if we can use such a phrase of one who was always withering, about the era of the Revolution ; and his Lear, we believe, was arranged in the year 1682. But the family to which he belongs is abundantly recorded in the Dunciad ; and his own name will be found amongst its catalogues of heroes.

With respect to *the author of the Tatler*, a very different explanation is requisite. Steevens means the reader to understand Addison ; but it does not follow that the particular paper in question was from his pen. Nothing, however, could be more natural than to quote from the common form of the play as then in possession of the stage. It was *there*, beyond a doubt, that a fine gentleman living upon town, and not professing any deep scholastic knowledge of literature (a light in which we are always to regard the writers of the Spectator, Guardian, &c.), would be likely to have learned anything he quoted from Macbeth. This we say generally of the writers in those periodical papers ; but, with reference to Addison in particular, it is time to correct the popular notion of his literary character, or at least to mark it by severer lines of distinction. It is already pretty well known, that Addison had no very intimate acquaintance with the literature of his own country. It is known also, that he did not think such an acquaintance any ways essential to the character of an elegant scholar and *littérateur*. Quite enough he found it, and more than enough for the time he had to spare, if he could maintain a tolerable familiarity with the foremost Latin poets, and a very slender one indeed with the Grecian. *How* slender, we can see in his " Travels." Of modern authors, none as yet had been published with notes, commentaries, or critical collations of the text ; and, accordingly, Addison looked upon all of them, except those few who professed themselves followers in the retinue and equipage of the ancients, as creatures of a lower race. Boileau, as a mere imitator and propagator of Horace, he read, and probably little else, amongst the French classics. Hence it arose that he took upon himself to speak sneeringly of Tasso. To this, which was a bold act for his timid mind, he was emboldened by the countenance of Boileau. Of the elder Italian authors, such as Ariosto, and, *a fortiori*, Dante, he knew absolutely nothing. Passing to our own literature, it is certain that Addison was profoundly ignorant of Chaucer and of Spenser. Milton only,—and why? simply because he was a brilliant scholar, and stands like a bridge between the Christian literature and the Pagan,—Addison had read and esteemed. There was also in the very constitution of Milton's mind, in the majestic regularity and planetary solemnity of its *epic* movements, something which he could understand and appreciate : as to the meteoric and incalculable eccentricities of the *dramatic* mind, as it dis-

played itself in the heroic age of our drama, amongst the Titans of 1590-1630, they confounded and overwhelmed him.

In particular, with regard to Shakspeare, we shall now proclaim a discovery which we made some twenty years ago. We, like others, from seeing frequent references to Shakspeare in the Spectator, had acquiesced in the common belief, that, although Addison was no doubt profoundly unlearned in Shakspeare's language, and thoroughly unable to do him justice (and this we might well assume, since his great rival Pope, who had expressly studied Shakspeare, was, after all, so memorably deficient in the appropriate knowledge),—yet, that of course he had a vague popular knowledge of the mighty poet's cardinal dramas. Accident only led us into a discovery of our mistake. Twice or thrice we had observed, that if Shakspeare were quoted, that paper turned out not to be Addison's; and at length, by express examination, we ascertained the curious fact, that Addison has never in one instance quoted or made any reference to Shakspeare.[1] But was this, as Steevens most disingenuously pretends, to be taken as an exponent of the public feeling towards Shakspeare? Was Addison's neglect representative of a general neglect? If so, whence came Rowe's edition, Pope's, Theobald's, Sir Thomas Hanmer's, Bishop Warburton's, all upon the heels of one another? With such facts staring him in the face, how shameless must be that critic who could, in support of such a thesis, refer to "*the author of the Tatler*," contemporary with all these editors. The truth is, Addison was well aware of Shakspeare's hold on the popular mind; too well aware of it. The feeble constitution of the poetic faculty, as existing in himself, forbade his sympathising with Shakspeare; the proportions were too colossal for his delicate vision; and yet, as one who sought popularity himself, he durst not shock what perhaps he viewed as a national prejudice. Those who have happened, like ourselves, to see the effect of passionate music and "deep-inwoven harmonics" upon the feeling of an idiot, may conceive what we mean. Such music does not utterly revolt the idiot; on the contrary, it has a strange but a horrid fascination for him: it alarms, irritates, disturbs, makes him profoundly unhappy; and chiefly by unlocking imperfect glimpses of thoughts and slumbering instincts, which it is for his peace to have entirely obscured, because for him they can be revealed only partially, and with the sad effect of throwing a baleful gleam upon his blighted condition. Do we mean, then, to compare Addison with an idiot? Not generally, by any means. Nobody can more sincerely admire him where he was a man of real genius, viz. in his delineations of character and manners, or in the exquisite delicacies of his humour. But assuredly Addison, as a poet, was amongst the sons of the feeble; and between the authors of Cato and of King Lear there was a gulf never to be bridged over.[2]

But Dryden, we are told, pronounced Shakspeare already in *his* day "*a little obsoletè*." Here now we have wilful, deliberate falsehood. *Obsolete*, in Dryden's meaning, does not imply that he was so with regard to his popularity (the question then at issue), but with regard to his diction and choice of words. To cite Dryden as a witness for any purpose against Shakspeare,—Dryden, who of all men had the most ransacked wit and exhausted language in celebrating the supremacy of Shakspeare's genius, does indeed require as much shamelessness in feeling as mendacity in principle.

But then Lord Shaftesbury, who may be taken as half way between Dryden and Pope (Dryden died in 1700, Pope was then twelve years old, and Lord S. wrote chiefly, we believe, between 1700 and 1710), "complains," it seems, "of his rude unpolished style, and his antiquated phrase and wit." What if he does? Let the whole truth be told, and then we shall see how much stress is to be laid upon such a judgment. The second Lord Shaftesbury, the author of the Characteristics, was the grandson of that famous political agitator, the Chancellor Shaftesbury, who passed his whole life in storms of his own creation. The second Lord Shaftesbury was a man of crazy constitution, querulous from ill health, and had received an eccentric education from his eccentric grandfather. He was practised daily in *talking* Latin, to which afterwards he added a competent study of the Greek; and finally he became unusually learned for his rank, but the most absolute and undistinguishing pedant that perhaps literature has to show. He sneers continually at the regular-built academic pedant; but he himself, though no academic, was essentially the very impersonation of pedantry. No thought however beautiful, no image however magnificent, could conciliate his praise as long as it was clothed in English; but present him with the most trivial common-places in Greek, and he unaffectedly fancied them divine; mistaking the pleasurable sense of his own power in a difficult and rare accomplishment for some peculiar force or beauty in the passage. Such was the outline of his literary taste. And was it upon Shakspeare only, or upon him chiefly, that he lavished his pedantry? Far from it. He attacked Milton with no less fervour; he attacked Dryden with a thousand times more. Jeremy Taylor he quoted only to ridicule; and even Locke, the confidential friend of his grandfather, he never alludes to without a sneer. As to Shakspeare, so far from Lord Shaftesbury's censures arguing his deficient reputation, the very fact of his noticing him at all proves his enormous popularity; for upon system he noticed those only who ruled the public taste. The insipidity of his objections to Shakspeare may be judged from this, that he comments in a spirit of absolute puerility upon the name *Desdemona*, as though intentionally formed from the Greek word for *superstition*. In fact, he had evidently read little beyond the list of names in Shakspeare; yet there is proof enough that the irresistible beauty of what little he *had* read was too much for all his pedantry, and startled him exceedingly; for ever afterwards he speaks of Shakspeare as one who, with a little aid from Grecian sources, really had something great and promising about him. As to modern authors, neither this Lord Shaftesbury nor Addison read anything for the latter years of their life but Bayle's Dictionary. And most of the little scintillations of erudition which may be found in the notes to the Characteristics, and in the Essays of Addison, are derived, almost without exception, and uniformly without acknowledgment, from Bayle.[3]

Finally, with regard to the sweeping assertion, that "for nearly a hundred years after his death Shakspeare was almost entirely neglected," we shall meet this scandalous falsehood by a rapid view of his fortunes during the century in question. The tradition has always been, that Shakspeare was honoured by the especial notice of Queen Elizabeth, as well as by that of James I. At one time we were disposed to question the truth of this tradition; but that was for want of

[1 "Mr De Quincey is certainly mistaken when he says that Addison has never in one instance quoted or made any reference to Shakspeare. No. 160 (of the *Spectator*) bears the signature of C., and immediately follows the *Vision of Mirza*, bearing the same signature."—*Charles Knight*. In No. 160 Shakspeare is placed amongst the first class of great geniuses.]

2 Probably Addison's fear of the national feeling was a good deal strengthened by his awe of Milton and of Dryden, both of whom had expressed a homage towards Shakspeare which language cannot transcend. Amongst his political friends, also, were many intense admirers of Shakspeare.

3 He who is weak enough to kick and spurn his own native literature, even if it were done with more knowledge than is shown by Lord Shaftesbury, will usually be kicked and spurned in his turn; and accordingly it has been often remarked, that the *Characteristics* are unjustly neglected in our days. For Lord Shaftesbury, with all his pedantry, was a man of great talents. Leibnitz had the sagacity to see this through the mists of a translation.

having read attentively the lines of Ben Jonson to the memory of Shakspeare, those generous lines which have so absurdly been taxed with faint praise. Jonson could make no mistake on this point: he, as one of Shakspeare's familiar companions, must have witnessed at the very time, and accompanied with friendly sympathy, every motion of royal favour towards Shakspeare. Now he, in words which leave no room for doubt, exclaims

> Sweet swan of Avon, what a sight it were
> To see thee in our waters yet appear;
> And make those flights upon the banks of Thames
> *That so did take Eliza and our James.*

These princes, then, *were* taken, were fascinated, with some of Shakspeare's dramas. In Elizabeth the approbation would probably be sincere. In James we can readily suppose it to have been assumed; for he was a pedant in a different sense from Lord Shaftesbury; not from undervaluing modern poetry, but from caring little or nothing for any poetry, although he wrote about its mechanic rules. Still the royal *imprimatur* would be influential and serviceable no less when offered hypocritically than in full sincerity. Next let us consider, at the very moment of Shakspeare's death, who were the leaders of the British youth, the *principes juventutis*, in the two fields, equally important to a great poet's fame, of rank and of genius? The Prince of Wales and John Milton; the first being then about sixteen years old, the other about eight. Now these two great powers, as we may call them, these presiding stars over all that was English in thought and action, were both impassioned admirers of Shakspeare. Each of them counts for many thousands. The Prince of Wales[1] had learned to appreciate Shakspeare, not originally from reading him, but from witnessing the court representations of his plays at Whitehall. Afterwards we know that he made Shakspeare his closet companion, for he was reproached with doing so by Milton. And we know also, from the just criticism pronounced upon the character and diction of Caliban by one of Charles's confidential counsellors, Lord Falkland, that the king's admiration of Shakspeare had impressed a determination upon the court reading. As to Milton, by double prejudices, puritanical and classical, his mind had been preoccupied against the full impressions of Shakspeare. And we know that there is such a thing as keeping the sympathies of love and admiration in a dormant state, or state of abeyance; an effort of self-conquest realized in more cases than one by the ancient fathers, both Greek and Latin, with regard to the profane classics. Intellectually they admired, and would not belie their admiration; but they did not give their hearts cordially, they did not abandon themselves to their natural impulses. They averted their eyes and weaned their attention from the dazzling object. Such, probably, was Milton's state of feeling towards Shakspeare after 1642, when the theatres were suppressed, and the fanatical fervour in its noontide heat. Yet even then he did not belie his reverence intellectually for Shakspeare; and in his younger days we know that he had spoken more enthusiastically of Shakspeare than he ever did again of any uninspired author. Not only did he address a sonnet to his memory, in which he declares that kings would wish to die, if by dying they could obtain such a monument in the hearts of men; but he also speaks of him in his *Il Penseroso* as the tutelary genius of the English stage. In this transmission of the torch (λαμπαδοφορια) Dryden succeeds to Milton; he was born nearly thirty years later; about thirty years they were contemporaries; and by thirty years, or nearly, Dryden survived his great leader. Dryden, in fact, lived out the seventeenth century. And we have now arrived within nine years of the era when the critical editions started in hot succession to one another. The names we have mentioned were the great influential names of the century. But of inferior homage there was no end. How came Betterton the actor, how came Davenant, how came Rowe, or Pope, by their intense (if not always sound) admiration for Shakspeare, unless they had found it fuming upwards like incense to the Pagan deities in ancient times from altars erected at every turning upon all the paths of men?

But it is objected that inferior dramatists were sometimes preferred to Shakspeare; and again, that vile travesties of Shakspeare were preferred to the authentic dramas. As to the first argument, let it be remembered, that if the saints of the chapel are always in the same honour, because *there* men are simply discharging a duty, which once due will be due for ever; the saints of the theatre, on the other hand, must bend to the local genius, and to the very reasons for having a theatre at all. Men go thither for amusement: this is the paramount purpose; and even acknowledged merit or absolute superiority must give way to it. Does a man at Paris expect to see Molière reproduced in proportion to his admitted precedency in the French drama? On the contrary, that very precedency argues such a familiarization with his works, that those who are in quest of relaxation will reasonably prefer any recent drama to that which, having lost all its novelty, has lost much of its excitement. We speak of ordinary minds; but in cases of *public* entertainments, deriving part of their power from scenery and stage pomp, novelty is for all minds an essential condition of attraction. Moreover, in some departments of the comic, Beaumont and Fletcher, when writing in combination, really had a freedom and breadth of manner which excels the comedy of Shakspeare. As to the altered Shakspeare as taking precedency of the genuine Shakspeare, no argument can be so frivolous. The public were never allowed a choice; the great majority of an audience even now cannot be expected to carry the real Shakspeare in their mind, so as to pursue a comparison between that and the alteration. Their comparisons must be exclusively amongst what they have opportunities of seeing; that is, between the various pieces presented to them by the managers of theatres. Further than this it is impossible for them to extend their office of judging and collating; and the degenerate taste which substituted the caprices of Davenant, the rants of Dryden, or the filth of Tate, for the jewellery of Shakspeare, cannot with any justice be charged upon the public, not one in a thousand of whom was furnished with any means of comparing, but exclusively upon those (viz. theatrical managers) who had the very amplest. Yet even in excuse for *them* much may be said. The very length of some plays compelled them to make alterations. The best of Shakspeare's dramas, King Lear, is the least fitted for representation; and, even for the vilest alteration, it ought in candour to be considered that possession is nine points of the law. He who would not have introduced, was often obliged to retain.

Finally, it is urged, that the small number of editions through which Shakspeare passed in the seventeenth century, furnishes a separate argument, and a conclusive one, against his popularity. We answer, that, considering the

[1] Perhaps the most bitter political enemy of Charles I. will have the candour to allow that, for a prince of those times, he was truly and eminently accomplished. His knowledge of the arts was considerable; and, as a patron of art, he stands foremost amongst all British sovereigns to this hour. He said truly of himself, and wisely as to the principle, that he understood English law as well as a gentleman ought to understand it; meaning that an attorney's minute knowledge of forms and technical niceties was illiberal. Speaking of him as an author, we must remember that the *Eikon Basilikè* is still unappropriated; that question is still open. But supposing the king's claim negatived, still, in his controversy with Henderson, in his negotiations at the Isle of Wight and elsewhere, he discovered a power of argument, a learning, and a strength of memory, which are truly admirable; whilst the whole of his accomplishments are recommended by a modesty and a humility as rare as they are unaffected.

bulk of his plays collectively, the editions were *not* few: compared with any known case, the copies sold of Shakspeare were quite as many as could be expected under the circumstances. Ten or fifteen times as much consideration went to the purchase of one great folio like Shakspeare, as would attend the purchase of a little volume like Waller or Donne. Without reviews, or newspapers, or advertisements to diffuse the knowledge of books, the progress of literature was necessarily slow, and its expansion narrow. But this is a topic which has always been treated unfairly, not with regard to Shakspeare only, but to Milton, as well as many others. The truth is, we have not facts enough to guide us; for the number of editions often tells nothing accurately as to the number of copies. With respect to Shakspeare it is certain, that, had his masterpieces been gathered into small volumes, Shakspeare would have had a most extensive sale. As it was, there can be no doubt, that from his own generation, throughout the seventeenth century, and until the eighteenth began to accommodate, not any greater popularity in *him*, but a greater taste for reading in the public, his fame never ceased to be viewed as a national trophy of honour; and the most illustrious men of the seventeenth century were no whit less fervent in their admiration than those of the eighteenth and the nineteenth, either as respected its strength and sincerity, or as respected its open profession.[1]

It is therefore a false notion, that the general sympathy with the merits of Shakspeare ever beat with a languid or intermitting pulse. Undoubtedly, in times when the functions of critical journals and of newspapers were not at hand to diffuse or to strengthen the impressions which emanated from the capital, all opinions must have travelled slowly into the provinces. But even then, whilst the perfect organs of communication were wanting, indirect substitutes were supplied by the necessities of the times, or by the instincts of political zeal. Two channels especially lay open between the great central organ of the national mind, and the remotest provinces. Parliaments were occasionally summoned (for the judges' circuits were too brief to produce much effect); and during their longest suspensions, the nobility, with large retinues, continually resorted to the court. But an intercourse more constant and more comprehensive was maintained through the agency of the two universities. Already, in the time of James I., the growing importance of the gentry, and the consequent birth of a new interest in political questions, had begun to express itself at Oxford, and still more so at Cambridge. Academic persons stationed themselves as sentinels at London, for the purpose of watching the court and the course of public affairs. These persons wrote letters, like those of the celebrated Joseph Mede, which we find in Ellis's Historical Collections, reporting to their fellow-collegians all the novelties of public life as they arose, or personally carried down such reports, and thus conducted the general feelings at the centre into lesser centres, from which again they were diffused into the ten thousand parishes of England; for (with a very few exceptions in favour of poor benefices, Welch or Cumbrian), every parish priest must unavoidably have spent his three years at one or other of the English universities. And by this mode of diffusion it is that we can explain the strength with which Shakspeare's thoughts and diction impressed themselves from a very early period upon the national literature, and even more generally upon the national thinking and conversation.[2]

The question therefore revolves upon us in threefold difficulty, How, having stepped thus prematurely into this inheritance of fame, leaping, as it were, thus abruptly into the favour alike of princes and the enemies of princes, had it become possible that in his native place (honoured still more in the final testimonies of his preference when founding a family mansion), such a man's history, and the personal recollections which cling so affectionately to the great

[1] The necessity of compression obliges us to omit many arguments and references by which we could demonstrate the fact, that Shakspeare's reputation was always in a progressive state; allowing only for the interruption of about seventeen years, which this poet, in common with all others, sustained, not so much from the state of war (which did not fully occupy four of those years), as from the triumph of a gloomy fanaticism. Deduct the twenty-three years of the seventeenth century which had elapsed before the first folio appeared, to this space add seventeen years of fanatical madness, during fourteen of which *all* dramatic entertainments were suppressed, the remainder is sixty years. And surely the sale of four editions of a vast folio in that space of time was an expression of an abiding interest. *No other poet, except Spenser, continued to sell throughout the century.* Besides, in arguing the case of a *dramatic* poet, we must bear in mind, that although readers of learned books might be diffused over the face of the land, the readers of poetry would be chiefly concentred in the metropolis; and such persons would have no need to buy what they heard at the theatres. But then comes the question, whether Shakspeare kept possession of the theatres. And we are really humiliated by the gross want of sense which has been shown, by Malone chiefly, but also by many others, in discussing this question. From the Restoration to 1682, says Malone, no more than four plays of Shakspeare's were performed by a principal company in London. "Such was the lamentable taste of those times, that the plays of Fletcher, Jonson, and Shirley, were much oftener exhibited than those of our author." What cant is this! If that taste were "lamentable," what are we to think of our own times, when plays a thousand times below those of Fletcher, or even of Shirley, continually displace Shakspeare? Shakspeare would himself have exulted in finding that he gave way only to dramatists so excellent. And, as we have before observed, both then and now, it is the very familiarity with Shakspeare which often banishes him from audiences honestly in quest of relaxation and amusement. Novelty is the very soul of such relaxation; but in our closets, when we are *not* unbending, when our minds are in a state of tension from intellectual cravings, then it is that we resort to Shakspeare; and oftentimes those who honour him most, like ourselves, are the most impatient of seeing his divine scenes disfigured by unequal representation (good, perhaps, in a single personation, bad in all the rest); or to hear his divine thoughts mangled in the recitation; or (which is worst of all) to hear them dishonoured and defeated by imperfect apprehension in the audience, or by defective sympathy. Meantime, if one theatre played only four of Shakspeare's dramas, another played at least seven. But the grossest folly of Malone is, in fancying the numerous alterations so many insults to Shakspeare, whereas they expressed as much homage to his memory as if the unaltered dramas had been retained. The substance *was* retained. The changes were merely concessions to the changing views of scenical propriety; sometimes, no doubt, made with a simple view to the revolution effected by Davenant at the restoration, in bringing *scenes* (in the painter's sense) upon the stage; sometimes also with a view to the altered fashions of the audience during the suspensions of the action, or perhaps to the introduction of *after-pieces*, by which, of course, the time was abridged for the main performance. A volume might be written upon this subject. Meantime let us never be told, that a poet was losing, or had lost his ground, who found in his lowest depression, amongst his almost idolatrous supporters, a great king distracted by civil wars, a mighty republican poet distracted by puritanical fanaticism, the greatest successor by far of that great poet, a papist and a bigoted royalist, and finally, the leading actor of the century, who gave and reflected the ruling impulses of his age.

[2] One of the profoundest tests by which we can measure the congeniality of an author with the national genius and temper, is the degree in which his thoughts or his phrases interweave themselves with our daily conversation, and pass into the currency of the language. *Few French authors, if any, have imparted one phrase to the colloquial idiom;* with respect to Shakspeare, a large dictionary might be made of such phrases as "win golden opinions," "in my mind's eye," "patience on a monument," "o'erstep the modesty of nature," "more honour'd in the breach than in the observance," "palmy state," "my poverty and not my will consents," and so forth, without end. This reinforcement of the general language, by aids from the mintage of Shakspeare, had already commenced in the seventeenth century.

intellectual potentates who have recommended themselves by gracious manners, could so soon and so utterly have been obliterated?

Malone, with childish irreflection, ascribes the loss of such memorials to the want of enthusiasm in his admirers. Local researches into private history had not then commenced. Such a taste, often petty enough in its management, was the growth of after-ages. Else how came Spenser's life and fortunes to be so utterly overwhelmed in oblivion? No poet of a high order could be more popular.

The answer we believe to be this: Twenty-six years after Shakspeare's death commenced the great parliamentary war: this it was, and the local feuds arising to divide family from family, brother from brother, upon which we must charge the extinction of traditions and memorials, doubtless abundant up to that era. The parliamentary contest, it will be said, did not last above three years; the king's standard having been first raised at Nottingham in August 1642, and the battle of Naseby (which terminated the open warfare) having been fought in June 1645. Or even if we extend its duration to the surrender of the last garrison, that war terminated in the spring of 1646. And the brief explosions of insurrection or of Scottish invasion which occurred on subsequent occasions were all locally confined; and none came near to Warwickshire, except the battle of Worcester, more than five years after. This is true; but a short war will do much to efface recent and merely personal memorials. And the following circumstances of the war were even more important than the general fact.

First of all, the very mansion founded by Shakspeare became the military head-quarters for the queen in 1644, when marching from the eastern coast of England to join the king in Oxford; and one such special visitation would be likely to do more serious mischief in the way of extinction, than many years of general warfare. Secondly, as a fact, perhaps, equally important, Birmingham, the chief town of Warwickshire, and the adjacent district, the seat of our hardware manufactures, was the very focus of disaffection towards the royal cause. Not only, therefore, would this whole region suffer more from internal and spontaneous agitation, but it would be the more frequently traversed vindictively from without, and harassed by flying parties from Oxford, or others of the king's garrisons. Thirdly, even apart from the political aspects of Warwickshire, this county happens to be the central one of England, as regards the roads between the north and south; and Birmingham has long been the great central axis,[1] in which all the radii from the four angles of England proper meet and intersect. Mere accident, therefore, of local position, much more when united with that avowed inveteracy of malignant feeling, which was bitter enough to rouse a re-action of bitterness in the mind of Lord Clarendon, would go far to account for the wreck of many memorials relating to Shakspeare, as well as for the subversion of that quiet and security for humble life, in which the traditional memory finds its best *nidus*. Thus we obtain one solution, and perhaps the main one, of the otherwise mysterious oblivion which had swept away all traces of the mighty poet, by the time when those quiet days revolved upon England, in which again the solitary agent of learned research might roam in security from house to house, gleaning those personal remembrances which, even in the fury of civil strife, might long have lingered by the chimney corner. But the fierce furnace of war had probably, by its *local* ravages, scorched this field of natural tradition, and thinned the gleaner's inheritance by three parts out of four. This, we repeat, may be one part of the solution to this difficult problem.

And if another is still demanded, possibly it may be found in the fact, hostile to the perfect consecration of Shakspeare's memory, that after all he was a player. Many a coarse-minded country gentleman, or village pastor, who would have held his town glorified by the distinction of having sent forth a great judge or an eminent bishop, might disdain to cherish the personal recollections which surrounded one whom custom regarded as little above a mountebank, and the illiberal law as a vagabond. The same degrading appreciation attached both to the actor in plays and to their author. The contemptuous appellation of "play book," served as readily to degrade the mighty volume which contained Lear and Hamlet, as that of "play-actor," or "player-man," has always served with the illiberal or the fanatical to dishonour the persons of Roscius or of Garrick, of Talma or of Siddons. Nobody, indeed, was better aware of this than the noble-minded Shakspeare; and feelingly he has breathed forth in his sonnets this conscious oppression under which he lay of public opinion, unfavourable by a double title to his own pretensions; for, being both dramatic author and dramatic performer, he found himself heir to a two-fold opprobrium, and at an era of English society when the weight of that opprobrium was heaviest. In reality, there was at this period a collision of forces acting in opposite directions upon the estimation of the stage and scenical art, and therefore of all the ministers in its equipage. Puritanism frowned upon these pursuits, as ruinous to public morals; on the other hand, loyalty could not but tolerate what was patronized by the sovereign; and it happened that Elizabeth, James, and Charles I., were all alike lovers and promoters of theatrical amusements, which were indeed more indispensable to the relief of court ceremony, and the monotony of aulic pomp, than in any other region of life. This royal support, and the consciousness that any brilliant success in these arts implied an unusual share of natural endowments, did something in mitigation of a scorn which must else have been intolerable to all generous natures.

But whatever prejudice might thus operate against the perfect sanctity of Shakspeare's posthumous reputation, it is certain that the splendour of his worldly success must have done much to obliterate that effect; his admirable colloquial talents a good deal, and his gracious affability still more. The wonder therefore will still remain, that Betterton, in less than a century from his death, should have been able to glean so little. And for the solution of this wonder we must throw ourselves chiefly upon the explanations we have made as to the parliamentary war, and the local ravages of its progress in the very district, of the very town, and the very house.

If further arguments are still wanted to explain this mysterious abolition, we may refer the reader to the following succession of disastrous events, by which it should seem that a perfect malice of misfortune pursued the vestiges of the mighty poet's steps. In 1613, the Globe theatre, with which he had been so long connected, was burned to the ground. Soon afterwards a great fire occurred in Stratford; and next (without counting upon the fire of London, just fifty years after his death, which, however, would consume many an important record from periods far more remote), the house of Ben Jonson, in which probably, as Mr Campbell suggests, might be parts of his correspondence, was also burned. Finally, there was an old tradition that Lady Barnard, the sole grand-daughter of Shakspeare, had carried off many of his papers from Stratford; and these papers have never since been traced.

In many of the elder lives it has been asserted, that John Shakspeare, the father of the poet, was a butcher,

[1] In fact, by way of representing to himself the system or scheme of the English roads, the reader has only to imagine one great letter X, or a St Andrew's cross, laid down from north to south, and decussating at Birmingham. Even Coventry, which makes a slight variation for one or two roads, and so far disturbs this decussation, by shifting it eastwards, is still in Warwickshire.

and in others that he was a woolstapler. It is now settled beyond dispute that he was a glover. This was his professed occupation in Stratford, though it is certain that, with this leading trade, from which he took his denomination, he combined some collateral pursuits; and it is possible enough that, as openings offered, he may have meddled with many. In that age, and in a provincial town, nothing like the exquisite subdivision of labour was attempted which we now see realized in the great cities of Christendom. And one trade is often found to play into another with so much reciprocal advantage, that even in our own days we do not much wonder at an enterprising man, in country places, who combines several in his own person. Accordingly John Shakspeare is known to have united with his town calling the rural and miscellaneous occupations of a farmer.

Meantime his avowed business stood upon a very different footing from the same trade as it is exercised in modern times. Gloves were in that age an article of dress more costly by much, and more elaborately decorated, than in our own. They were a customary present from some cities to the judges of assize, and to other official persons; a custom of ancient standing, and in some places, we believe, still subsisting; and in such cases it is reasonable to suppose that the gloves must originally have been more valuable than the trivial modern article of the same name. So also, perhaps, in their origin, of the gloves given at funerals. In reality, whenever the simplicity of an age makes it difficult to renew the parts of a wardrobe except in capital towns of difficult access, prudence suggests that such wares should be manufactured of more durable materials; and, being so, they become obviously susceptible of more lavish ornament. But it will not follow, from this essential difference in the gloves of Shakspeare's age, that the glover's occupation was more lucrative. Doubtless he sold more costly gloves, and upon each pair had a larger profit; but for that very reason he sold fewer. Two or three gentlemen "of worship" in the neighbourhood might occasionally require a pair of gloves, but it is very doubtful whether any inhabitant of Stratford would ever call for so mere a luxury.

The practical result, at all events, of John Shakspeare's various pursuits does not appear permanently to have met the demands of his establishment; and in his maturer years there are indications still surviving that he was under a cloud of embarrassment. He certainly lost at one time his social position in the town of Stratford; but there is a strong presumption, in *our* construction of the case, that he finally retrieved it; and for this retrieval of a station which he had forfeited by personal misfortunes or neglect, he was altogether indebted to the filial piety of his immortal son.

Meantime the earlier years of the elder Shakspeare wore the aspect of rising prosperity, however unsound might be the basis on which it rested. There can be little doubt that William Shakspeare, from his birth up to his tenth or perhaps his eleventh year, lived in careless plenty, and saw nothing in his father's house but that style of liberal housekeeping which has ever distinguished the upper yeomanry and the rural gentry of England. Probable enough it is that the resources for meeting this liberality were not strictly commensurate with the family income, but were sometimes allowed to entrench, by means of loans or mortgages, upon capital funds. The stress upon the family finances was perhaps at times severe; and that it was borne at all, must be imputed to the large and even splendid portion which John Shakspeare received with his wife.

This lady, for such she really was in an eminent sense, by birth as well as by connections, bore the beautiful name of Mary Arden, a name derived from the ancient forest district[1] of the county; and doubtless she merits a more elaborate notice than our slender materials will furnish. To have been *the mother of Shakspeare*,—how august a title to the reverence of infinite generations, and of centuries beyond the vision of prophecy. A plausible hypothesis has been started in modern times, that the facial structure, and that the intellectual conformation, may be deduced more frequently from the corresponding characteristics in the mother than in the father. It is certain that no very great man has ever existed, but that his greatness has been rehearsed and predicted in one or other of his parents. And it cannot be denied, that in the most eminent men, where we have had the means of pursuing the investigation, the mother has more frequently been repeated and reproduced than the father. We have known cases where the mother has furnished all the intellect, and the father all the moral sensibility; upon which assumption, the wonder ceases that Cicero, Lord Chesterfield, and other brilliant men, who took the utmost pains with their sons, should have failed so conspicuously; for possibly the mothers had been women of excessive and even exemplary stupidity. In the case of Shakspeare, each parent, if we had any means of recovering their characteristics, could not fail to furnish a study of the most profound interest; and with regard to his mother in particular, if the modern hypothesis be true, and if we are indeed to deduce from *her* the stupendous intellect of her son, in that case she must have been a benefactress to her husband's family beyond the promises of fairyland or the dreams of romance; for it is certain that to her chiefly this family was also indebted for their worldly comfort.

Mary Arden was the youngest daughter and the heiress of Robert Arden of Wilmecote, Esq. in the county of Warwick. The family of Arden was even then of great antiquity. About one century and a quarter before the birth of William Shakspeare, a person bearing the same name as his maternal grandfather had been returned by the commissioners in their list of the Warwickshire gentry; he was there styled Robert Arden, Esq. of Bromich. This was in 1433, or the 12th year of Henry VI. In Henry VII.'s reign, the Ardens received a grant of lands from the crown; and in 1568, four years after the birth of William Shakspeare, Edward Arden, of the same family, was sheriff of the county. Mary Arden was therefore a young lady of excellent descent and connections, and an heiress of considerable wealth. She brought to her husband, as her marriage portion, the landed estate of Asbies, which, upon any just valuation, must be considered as a handsome dowry for a woman of her station. As this point has been contested, and as it goes a great way towards determining the exact social position of the poet's parents, let us be excused for sifting it a little more narrowly than might else seem warranted by the proportions of our present life. Every question which it can be reasonable to raise at all, it must be reasonable to treat with at least so much of minute research as may justify the conclusions which it is made to support.

The estate of Asbies contained fifty acres of arable land, six of meadow, and a right of commonage. What may we assume to have been the value of its fee-simple? Malone, who allows the total fortune of Mary Arden to have been L.110. 13s. 4d., is sure that the value of Asbies could not have been more than one hundred pounds. But why? Because, says he, the "average" rent of land at that time was no more than three shillings per acre. This we deny; but

[1] And probably so called by some remote ancestor who had emigrated from the forest of Ardennes, in the Netherlands, and *now* for ever memorable to English ears from its proximity to Waterloo.

Shakspeare.

upon that assumption, the total yearly rent of fifty-six acres would be exactly eight guineas.[1] And therefore, in assigning the value of Asbies at one hundred pounds, it appears that Malone must have estimated the land at no more than twelve years' purchase, which would carry the value to L.100. 16s. "Even at this estimate," as the latest annotator[2] on this subject *justly* observes, "Mary Arden's portion was a larger one than was usually given to a landed gentleman's daughter." But this writer objects to Malone's principle of valuation. "We find," says he, "that John Shakspeare also farmed the meadow of Tugton, containing sixteen acres, at the rate of eleven shillings per acre. Now what proof has Mr Malone adduced that the acres of Asbies were not as valuable as those of Tugton? And if they were so, the former estate must have been worth between three and four hundred pounds." In the main drift of his objections we concur with Mr Campbell. But as they are liable to some criticism, let us clear the ground of all plausible cavils, and then see what will be the result. Malone, had he been alive, would probably have answered, that Tugton was a farm specially privileged by nature; and that if any man contended for so unusual a rent as eleven shillings an acre for land not known to him, the *onus probandi* would lie upon *him*. Be it so; eleven shillings is certainly above the ordinary level of rent, but three shillings is below it. We contend, that for tolerably good land, situated advantageously, that is, with a ready access to good markets and good fairs, such as those of Coventry, Birmingham, Gloucester, Worcester, Shrewsbury, &c., one noble might be assumed as the annual rent; and that in such situations twenty years' purchase was not a valuation, even in Elizabeth's reign, very unusual. Let us, however, assume the rent at only five shillings, and land at sixteen years' purchase: upon this basis, the rent would be L.14, and the value of the fee-simple L.224. Now, if it were required to equate that sum with its present value, a very operose[3] calculation might be requisite. But contenting ourselves with the gross method of making such equations between 1560 and the current century, that is, multiplying by five, we shall find the capital value of the estate to be eleven hundred and twenty pounds, whilst the annual rent would be exactly seventy. But if the estate had been sold, and the purchase-money lent upon mortgage (the only safe mode of investing money at that time), the annual interest would have reached L.28, equal to L.140 of modern money; for mortgages in Elizabeth's age readily produced ten per cent.

A woman who should bring at this day an annual income of L.140 to a provincial tradesman, living in a sort of *rus in urbe*, according to the simple fashions of rustic life, would assuredly be considered as an excellent match. And there can be little doubt that Mary Arden's dowry it was which, for some ten or a dozen years succeeding to his marriage, raised her husband to so much social consideration in Stratford. In 1550 John Shakspeare is supposed to have first settled in Stratford, having migrated from some other part of Warwickshire. In 1557 he married Mary Arden; in 1565, the year subsequent to the birth of his son William his third child, he was elected one of the aldermen; and in the year 1568 he became first magistrate of the town, by the title of high bailiff. This year we may assume to have been that in which the prosperity of this family reached its zenith; for in this year it was, over and above the presumptions furnished by his civic honours, that he obtained a grant of arms from Clarencieux of the Heralds' College. On this occasion he declared himself worth five hundred pounds derived from his ancestors. And we really cannot understand the right by which critics, living nearly three centuries from his time, undertake to know his affairs better than himself, and to tax him with either inaccuracy or falsehood. No man would be at leisure to court heraldic honours when he knew himself to be embarrassed, or apprehended that he soon might be so. A man whose anxieties had been fixed at all upon his daily livelihood would, by this chase after the aërial honours of heraldry, have made himself a butt for ridicule such as no fortitude could enable him to sustain.

In 1568, therefore, when his son William would be moving through his fifth year, John Shakspeare (now honoured by the designation of *Master*) would be found at times in the society of the neighbouring gentry. Ten years in advance of this period he was already in difficulties. But there is no proof that these difficulties had then reached a point of degradation, or of memorable distress. The sole positive indications of his decaying condition are, that in 1578 he received an exemption from the small weekly assessment levied upon the aldermen of Stratford for the relief of the poor; and that in the following year, 1579, he is found enrolled amongst the defaulters in the payment of taxes. The latter fact undoubtedly goes to prove that, like every man who is falling back in the world, he was occasionally in arrears. Paying taxes is not like the honours awarded or the processions regulated by Clarencieux; no man is ambitious of precedency there; and if a laggard pace in that duty is to be received as evidence of pauperism, nine tenths of the English people might occasionally be classed as paupers. With respect to his liberation from the weekly assessment, that may bear a construction different from the one which it has received. This payment, which could never have been regarded as a burthen, not amounting to five pounds annually of our present money, may have been held up as an exponent of wealth and consideration; and John Shakspeare may have been required to resign it as an honourable distinction, not suitable to the circumstances of an embarrassed man. Finally, the fact of his being indebted to Robert Sadler, a baker, in the sum of five pounds, and his being under the necessity of bringing a friend as security for the payment, proves nothing at

[1] Let not the reader impute to us the gross anachronism of making an estimate for Shakspeare's days in a coin which did not exist until a century, within a couple of years, after Shakspeare's birth, and did not settle to the value of twenty-one shillings until a century after his death. The nerve of such an anachronism would lie in putting the estimate into a mouth of that age. And this is precisely the blunder into which the foolish forger of Vortigern, &c. has fallen. He does not indeed directly mention guineas; but indirectly and virtually he does, by repeatedly giving us accounts imputed to Shakspearian contemporaries, in which the sum-total amounts to L.5. 5s.; or to L.26. 5s.; or, again, to L.17. 17s. 6d. A man is careful to subscribe L.14. 14s. and so forth. But how could such amounts have arisen unless under a secret reference to guineas, which were not in existence until Charles II.'s reign; and, moreover, to guineas at their final settlement by law into twenty-one shillings each, which did not take place until George I.'s reign.

[2] Thomas Campbell the poet, in his eloquent Remarks on the Life and Writings of William Shakspeare, prefixed to a popular edition of the poet's dramatic works. London, 1838.

[3] After all the assistance given to such equations between different times or different places by Sir George Shuckborough's tables, and other similar investigations, it is still a very difficult problem, complex, and, after all, merely tentative in the results, to assign the true value in such cases; not only for the obvious reason, that the powers of money have varied in different directions with regard to different objects, and in different degrees where the direction has on the whole continued the same, but because the very objects to be taken into computation are so indeterminate, and vary so much, not only as regards century and century, kingdom and kingdom, but also, even in the same century and the same kingdom, as regards rank and rank. That which is a mere necessary to one, is a luxurious superfluity to another. And, in order to ascertain these differences, it is an indispensable qualification to have studied the habits and customs of the several classes concerned, together with the variations of those habits and customs.

all. There is not a town in Europe in which opulent men cannot be found that are backward in the payment of their debts. And the probability is, that Master Sadler acted like most people who, when they suppose a man to be going down in the world, feel their respect for him sensibly decaying, and think it wise to trample him under foot, provided only in that act of trampling they can squeeze out of him their own individual debt. Like that terrific chorus in Spohr's oratorio of St Paul, "*stone him to death*" is the cry of the selfish and the illiberal amongst creditors, alike towards the just and the unjust amongst debtors.

It was the wise and beautiful prayer of Agar, "Give me neither poverty nor riches;" and, doubtless, for quiet, for peace, and the *latentis semita vitæ*, that is the happiest dispensation. But, perhaps, with a view to a school of discipline and of moral fortitude, it might be a more salutary prayer, "Give me riches *and* poverty, and afterwards neither." For the transitional state between riches and poverty will teach a lesson both as to the baseness and the goodness of human nature, and will impress that lesson with a searching force, such as no borrowed experience ever can approach. Most probable it is that Shakspeare drew some of his powerful scenes in the Timon of Athens, those which exhibit the vileness of ingratitude and the impassioned frenzy of misanthropy, from his personal recollections connected with the case of his own father. Possibly, though a cloud of 270 years now veils it, this very Master Sadler, who was so urgent for his five pounds, and who so little apprehended that he should be called over the coals for it in the Encyclopædia Britannica, may have sate for the portrait of that Lucullus who says of Timon—

> Alas, good lord! a noble gentleman 'tis, if he would not keep so good a house. Many a time and often I have dined with him, and told him on't; and come again to supper to him, of purpose to have him spend less: and yet he would embrace no counsel, take no warning by my coming. Every man has his fault, and honesty is his; I have told him on't, but I could never get him from it.

For certain years, perhaps, John Shakspeare moved on in darkness and sorrow:

> His familiars from his buried fortunes
> Slunk all away; left their false vows with him,
> Like empty purses pick'd: and his poor self,
> A dedicated beggar to the air,
> With his disease of all-shunn'd poverty,
> Walk'd, like contempt, alone.

We, however, at this day are chiefly interested in the case as it bears upon the education and youthful happiness of the poet. Now if we suppose that from 1568, the high noon of the family prosperity, to 1578, the first year of their mature embarrassments, one half the interval was passed in stationary sunshine, and the latter half in the gradual twilight of declension, it will follow that the young William had completed his tenth year before he heard the first signals of distress; and for so long a period his education would probably be conducted on as liberal a scale as the resources of Stratford would allow. Through this earliest section of his life he would undoubtedly rank as a gentleman's son, possibly as the leader of his class, in Stratford. But what rank he held through the next ten years, or, more generally, what was the standing in society of Shakspeare until he had created a new station for himself by his own exertions in the metropolis, is a question yet unsettled, but which has been debated as keenly as if it had some great dependencies. Upon this we shall observe, that could we by possibility be called to settle beforehand what rank were best for favouring the development of intellectual powers, the question might wear a face of deep practical importance; but when the question is simply as to a matter of fact, what *was* the rank held by a man whose intellectual development has long ago been completed, this becomes a mere question of curiosity. The tree has fallen; it is confessedly the noblest of all the forest; and we must therefore conclude that the soil in which it flourished was either the best possible, or, if not so, that any thing bad in its properties had been disarmed and neutralized by the vital forces of the plant, or by the benignity of nature. If any future Shakspeare were likely to arise, it might be a problem of great interest to agitate, whether the condition of a poor man or of a gentleman were best fitted to nurse and stimulate his faculties. But for the actual Shakspeare, since what he was he was, and since nothing greater can be imagined, it is now become a matter of little moment whether his course lay for fifteen or twenty years through the humilities of absolute poverty, or through the chequered paths of gentry lying in the shade. Whatever *was*, must, in this case at least, have been the best, since it terminated in producing Shakspeare; and thus far we must all be optimists.

Yet still, it will be urged, the curiosity is not illiberal which would seek to ascertain the precise career through which Shakspeare ran. This we readily concede; and we are anxious ourselves to contribute any thing in our power to the settlement of a point so obscure. What we have wished to protest against is the spirit of partisanship in which this question has too generally been discussed. For, whilst some with a foolish affectation of plebeian sympathies overwhelm us with the insipid commonplaces about birth and ancient descent, as honours containing nothing meritorious, and rush eagerly into an ostentatious exhibition of all the circumstances which favour the notion of a humble station and humble connections; others, with equal forgetfulness of true dignity, plead with the intemperance and partiality of a legal advocate for the pretensions of Shakspeare to the hereditary rank of gentleman. Both parties violate the majesty of the subject. When we are seeking for the sources of the Euphrates or the St Lawrence, we look for no proportions to the mighty volume of waters in that particular summit amongst the chain of mountains which embosoms its earliest fountains, nor are we shocked at the obscurity of these fountains. Pursuing the career of Mahommed, or of any man who has memorably impressed his own mind or agency upon the revolutions of mankind, we feel solicitude about the circumstances which might surround his cradle to be altogether unseasonable and impertinent. Whether he were born in a hovel or a palace, whether he passed his infancy in squalid poverty, or hedged around by the glittering spears of body-guards, as mere questions of fact may be interesting; but, in the light of either accessories or counteragencies to the native majesty of the subject, are trivial and below all philosophic valuation. So with regard to the creator of Lear and Hamlet, of Othello and Macbeth; to him from whose golden urns the nations beyond the far Atlantic, the multitude of the isles, and the generations unborn in Australian climes, even to the realms ot the rising sun (the ἀνατολαι ἠελιοιο), must in every age draw perennial streams of intellectual life, we feel that the little accidents of birth and social condition are so unspeakably below the grandeur of the theme, are so irrelevant and disproportioned to the real interest at issue, so incommensurable with any of its relations, that a biographer of Shakspeare at once denounces himself as below his subject if he can entertain such a question as seriously affecting the glory of the poet. In some legends of saints, we find that they were born with a lambent circle or golden aureola about their heads. This angelic coronet shed light alike upon the chambers of a cottage or a palace, upon the gloomy limits of a dungeon or the vast expansion of a cathedral; but the cottage, the palace, the dungeon, the cathedral, were all equally incapable of adding one ray of colour or one pencil of light to the supernatural halo.

Having therefore thus pointedly guarded ourselves from misconstruction, and consenting to entertain the question

as one in which we, the worshippers of Shakspeare, have an interest of curiosity, but in which he, the object of our worship, has no interest of glory, we proceed to state what appears to us the result of the scanty facts surviving when collated with each other.

By his mother's side, Shakspeare was an authentic gentleman. By his father's he would have stood in a more dubious position; but the effect of municipal honours to raise and illustrate an equivocal rank has always been acknowledged under the popular tendencies of our English political system. From the sort of lead, therefore, which John Shakspeare took at one time amongst his fellow-townsmen, and from his rank of first magistrate, we may presume that, about the year 1568, he had placed himself at the head of the Stratford community. Afterwards he continued for some years to descend from this altitude; and the question is, at what point this gradual degradation may be supposed to have settled. Now we shall avow it as our opinion, that the composition of society in Stratford was such that, even had the Shakspeare family maintained their superiority, the main body of their daily associates must still have been found amongst persons below the rank of gentry. The poet must inevitably have mixed chiefly with mechanics and humble tradesmen, for such people composed perhaps the total community. But had there even been a gentry in Stratford, since they would have marked the distinctions of their rank chiefly by greater reserve of manners, it is probable that, after all, Shakspeare, with his enormity of delight in exhibitions of human nature, would have mostly cultivated that class of society in which the feelings are more elementary and simple, in which the thoughts speak a plainer language, and in which the restraints of factitious or conventional decorum are exchanged for the restraints of mere sexual decency. It is a noticeable fact to all who have looked upon human life with an eye of strict attention, that the abstract image of womanhood, in its loveliness, its delicacy, and its modesty, nowhere makes itself more impressive or more advantageously felt than in the humblest cottages, because it is there brought into immediate juxtaposition with the grossness of manners and the careless license of language incident to the fathers and brothers of the house. And this is more especially true in a nation of unaffected sexual gallantry,[1] such as the English and the Gothic races in general; since, under the immunity which their women enjoy from all servile labours of a coarse or out-of-doors order, by as much lower as they descend in the scale of rank, by so much more do they benefit under the force of contrast with the men of their own level. A young man of that class, however noble in appearance, is somewhat degraded in the eyes of women, by the necessity which his indigence imposes of working under a master; but a beautiful young woman, in the very poorest family, unless she enters upon a life of domestic servitude (in which case her labours are light, suited to her sex, and withdrawn from the public eye), so long in fact as she stays under her father's roof, is as perfectly her own mistress and *sui juris* as the daughter of an earl. This personal dignity, brought into stronger relief by the mercenary employments of her male connections, and the feminine gentleness of her voice and manners, exhibited under the same advantages of contrast, oftentimes combine to make a young cottage beauty as fascinating an object as any woman of any station.

Hence we may in part account for the great event of Shakspeare's early manhood, his premature marriage. It has always been known, or at least traditionally received for a fact, that Shakspeare had married whilst yet a boy; and that his wife was unaccountably older than himself. In the very earliest biographical sketch of the poet, compiled by Rowe, from materials collected by Betterton the actor, it was stated (and that statement is now ascertained to have been correct), that he had married Anne Hathaway, "the daughter of a substantial yeoman." Further than this nothing was known. But in September 1836 was published a very remarkable document, which gives the assurance of law to the time and fact of this event, yet still, unless collated with another record, does nothing to lessen the mystery which had previously surrounded its circumstances. This document consists of two parts: the first, and principal, according to the logic of the case, though second according to the arrangement, being a *license* for the marriage of William Shakspeare with Anne Hathaway, under the condition "of *once* asking of the bannes of matrimony," that is, in effect, dispensing with two out of the three customary askings; the second or subordinate part of the document being a *bond* entered into by two sureties, viz. Fulke Sandells and John Rychardson, both described as *agricolæ* or yeomen, and both marksmen (that is, incapable of writing, and therefore subscribing by means of *marks*), for the payment of forty pounds sterling, in the event of Shakspeare, yet a minor, and incapable of binding himself, failing to fulfil the conditions of the license. In the bond, drawn up in Latin, there is no mention of Shakspeare's name; but in the license, which is altogether English, *his* name, of course, stands foremost; and as it may gratify the reader to see the very words and orthography of the original, we here extract the *operative* part of this document, prefacing only, that the license is attached by way of explanation to the bond. "The condition of this obligation is suche, that if herafter there shall not appere any lawfull lett or impediment, by reason of any precontract, &c., but that Willm. Shagspere, one thone ptie" [on the one party], "and Anne Hathwey of Stratford, in the diocess of Worcester, maiden, may lawfully solemnize matrimony together; and in the

---

[1] Never was the *esse quam videri* in any point more strongly discriminated than in this very point of gallantry to the female sex, as between England and France. In France, the verbal homage to woman is so excessive as to betray its real purpose, viz. that it is a mask for secret contempt. In England, little is *said;* but, in the mean time, we allow our sovereign ruler to be a woman; which in France is impossible. Even that fact is of some importance, but less so than what follows. In every country whatsoever, if any principle has a deep root in the moral feelings of the people, we may rely upon its showing itself, by a thousand evidences, amongst the very lowest ranks, and in their daily intercourse, and their *undress* manners. Now in England there is, and always has been, a manly feeling, most widely diffused, of unwillingness to see labours of a coarse order, or requiring muscular exertions, thrown upon women. Pauperism, amongst other evil effects, has sometimes locally disturbed this predominating sentiment of Englishmen; but never at any time with such depth as to kill the root of the old hereditary manliness. Sometimes at this day a gentleman, either from carelessness, or from over-ruling force of convenience, or from real defect of gallantry, will allow a female servant to carry his portmanteau for him; though, after all, that spectacle is a rare one. And everywhere women of all ages engage in the pleasant, nay elegant, labours of the hay field; but in Great Britain women are never suffered to mow, which is a most athletic and exhausting labour, nor to load a cart, nor to drive a plough or hold it. In France, on the other hand, before the Revolution (at which period the pseudo-homage, the lip-honour, was far more ostentatiously professed towards the female sex than at present), a Frenchman of credit, and vouching for his statement by the whole weight of his name and personal responsibility (M. Simond, now an American citizen), records the following abominable scene as one of no uncommon occurrence: A woman was in some provinces yoked side by side with an ass to the plough or the harrow; and M. Simond protests that it excited no horror to see the driver distributing his lashes impartially between the woman and her brute yoke-fellow. So much for the wordy pomps of French gallantry. In England, we trust, and we believe, that any man, caught in such a situation, and in such an abuse of his power (supposing the case otherwise a possible one), would be killed on the spot.

same afterwards remaine and continew like man and wiffe. And, moreover, if the said Willm. Shagspere do not proceed to solemnization of mariadg with the said Anne Hathwey, without the consent of hir frinds;—then the said obligation" [viz. to pay forty pounds] "to be voyd and of none effect, or els to stand & abide in full force and vertue."

What are we to think of this document? Trepidation and anxiety are written upon its face. The parties are not to be married by a special license; not even by an ordinary license; in that case no proclamation of banns, no public asking at all, would have been requisite. Economical scruples are consulted; and yet the regular movement of the marriage "through the bell-ropes"[1] is disturbed. Economy, which retards the marriage, is here evidently in collision with some opposite principle which precipitates it. How is all this to be explained? Much light is afforded by the date when illustrated by another document. The bond bears date on the 28th day of November in the 25th year of our lady the queen, that is, in 1582. Now the baptism of Shakspeare's eldest child, Susanna, is registered on the 26th of May in the year following. Suppose, therefore, that his marriage was solemnized on the 1st day of December; it was barely possible that it could be earlier, considering that the sureties, drinking, perhaps, at Worcester throughout the 28th of November, would require the 29th, in so dreary a season, for their return to Stratford; after which some preparation might be requisite to the bride, since the marriage was *not* celebrated at Stratford. Next suppose the birth of Miss Susanna to have occurred, like her father's, two days before her baptism, viz. on the 24th of May. From December the 1st to May the 24th, both days inclusively, are 175 days; which, divided by seven, gives precisely twenty-five weeks, that is to say, six months short by one week. Oh, fie, Miss Susanna, you came rather before you were wanted.

Mr Campbell's comment upon the affair is, that "*if* this was the case," viz. if the baptism were really solemnized on the 26th of May, "the poet's first child would *appear* to have been born only six months and eleven days after the bond was entered into." And he then concludes that, on this assumption, "Miss Susanna Shakspeare came into the world a little prematurely." But this is to doubt where there never was any ground for doubting; the baptism was *certainly* on the 26th of May; and, in the next place, the calculation of six months and eleven days is sustained by substituting lunar months for calendar, and then only by supposing the marriage to have been celebrated on the very day of subscribing the bond in Worcester, and the baptism to have been coincident with the birth; of which suppositions the latter is improbable, and the former, considering the situation of Worcester, impossible.

Strange it is, that, whilst all biographers have worked with so much zeal upon the most barren dates or most baseless traditions in the great poet's life, realising in a manner the chimeras of Laputa, and endeavouring "to extract sunbeams from cucumbers," such a story with regard to such an event, no fiction of village scandal, but involved in legal documents, a story so significant and so eloquent to the intelligent, should formerly have been dismissed without notice of any kind, and even now, after the discovery of 1836, with nothing beyond a slight conjectural insinuation. For our parts, we should have been the last amongst the biographers to unearth any forgotten scandal, or, after so vast a lapse of time, and when the grave had shut out all but charitable thoughts, to point any moral censures at a simple case of natural frailty, youthful precipitancy of passion, of all trespasses the most venial, where the final intentions are honourable. But in this case there seems to have been something more in motion than passion or the ardour of youth. "I like not," says Parson Evans (alluding to Falstaff in masquerade), "I like not when a woman has a great peard; I spy a great peard under her muffler." Neither do we like the spectacle of a mature young woman, five years past her majority, wearing the semblance of having been led astray by a boy who had still two years and a half to run of his minority. Shakspeare himself, looking back on this part of his youthful history from his maturest years, breathes forth pathetic counsels against the errors into which his own inexperience had been ensnared. The disparity of years between himself and his wife he notices in a beautiful scene of the Twelfth Night. The Duke Orsino, observing the sensibility which the pretended Cesario had betrayed on hearing some touching old snatches of a love strain, swears that his beardless page must have felt the passion of love, which the other admits. Upon this the dialogue proceeds thus:

Duke. What kind of woman is't?
Viola. Of your complexion.
Duke. She is not worth thee then:—What years?
Viola. I' faith,
About your years, my lord.
Duke. Too old, by heaven. *Let still the woman take*
An elder than herself: so wears she to him,
So sways she level in her husband's heart.
For, boy, however we do praise ourselves,
Our fancies are more giddy and unfirm,
More longing, wavering, sooner lost and worn,
Than women's are.
Viola. I think it well, my lord.
Duke. Then *let thy love be younger than thyself,*
Or thy affection cannot hold the bent;
For women are as roses, whose fair flower,
Being once display'd, doth fall that very hour.

These counsels were uttered nearly twenty years after the event in his own life to which they probably look back; for this play is supposed to have been written in Shakspeare's thirty-eighth year. And we may read an earnestness in pressing the point as to the *inverted* disparity of years, which indicates pretty clearly an appeal to the lessons of his personal experience. But his other indiscretion, in having yielded so far to passion and opportunity as to crop by prelibation, and before they were hallowed, those flowers of paradise which belonged to his marriage-day; this he adverts to with even more solemnity of sorrow, and with more pointed energy of moral reproof, in the very last drama which is supposed to have proceeded from his pen, and therefore with the force and sanctity of testamentary counsel. The Tempest is all but ascertained to have been composed in 1611, that is, about five years before the poet's death; and indeed could not have been composed much earlier; for the very incident which suggested the basis of the plot, and of the local scene, viz. the shipwreck of Sir George Somers on the Bermudas (which were in consequence denominated the Somers' Islands), did not occur until the year 1609. In the opening of the fourth act, Prospero formally betrothes his daughter to Ferdinand; and in doing so he pays the prince a well-merited compliment of having "worthily purchas'd" this rich jewel, by the patience with which, for her sake, he had supported harsh usage, and other painful circumstances of his trial. But, he adds solemnly,

If thou dost break her virgin knot before
All sanctimonious ceremonies may
With full and holy rite be minister'd;

[1] Amongst people of humble rank in England, who only were ever asked in church, until the new-fangled systems of marriage came up within the last ten or fifteen years, during the currency of the three Sundays on which the banns were proclaimed by the clergyman from the reading desk, the young couple elect were said jocosely to be "hanging in the bell-ropes;" alluding perhaps to the joyous peal contingent on the final completion of the marriage.

in that case what would follow?

> No sweet aspersion shall the heavens let fall,
> To make this contract grow; *but barren hate,*
> *Sour-ey'd disdain and discord, shall bestrew*
> *The union of your bed with weeds so loathly*
> *That you shall hate it both.* Therefore take heed,
> As Hymen's lamps shall light you.

The young prince assures him in reply, that no strength of opportunity, concurring with the uttermost temptation, not

> the murkiest den,
> The most opportune place, the strong'st suggestion
> Our worser genius can———

should ever prevail to lay asleep his jealousy of self-control, so as to take any advantage of Miranda's innocence. And he adds an argument for this abstinence, by way of reminding Prospero, that not honour only, but even prudential care of his own happiness, is interested in the observance of his promise. Any unhallowed anticipation would, as he insinuates,

> take away
> The edge of that day's celebration,
> When I shall think, or Phœbus' steeds are founder'd,
> Or night kept chain'd below;

that is, when even the winged hours would seem to move too slowly. Even thus Prospero is not quite satisfied: during his subsequent dialogue with Ariel, we are to suppose that Ferdinand, in conversing apart with Miranda, betrays more impassioned ardour than the wise magician altogether approves. The prince's caresses have not been unobserved; and thus Prospero renews his warning:

> Look thou be true: do not give dalliance
> Too much the rein: the strongest oaths are straw
> To the fire i' the blood: be more abstemious,
> Or else—good night your vow.

The royal lover re-assures him of his loyalty to his engagements; and again the wise father, so honourably jealous for his daughter, professes himself satisfied with the prince's pledges.

Now in all these emphatic warnings, uttering the language "of that sad wisdom folly leaves behind," who can avoid reading, as in subtile hieroglyphics, the secret record of Shakspeare's own nuptial disappointments? We, indeed, that is, universal posterity through every age, have reason to rejoice in these disappointments; for to them, past all doubt, we are indebted for Shakspeare's subsequent migration to London, and his public occupation, which, giving him a deep pecuniary interest in the productions of his pen, such as no other literary application of his powers could have approached in that day, were eventually the means of drawing forth those divine works which have survived their author for our everlasting benefit.

Our own reading and deciphering of the whole case is as follows. The Shakspeares were a handsome family, both father and sons. This we assume upon the following grounds: First, on the presumption arising out of John Shakspeare's having won the favour of a young heiress higher in rank than himself; secondly, on the presumption involved in the fact of three amongst his four sons having gone upon the stage, to which the most obvious (and perhaps in those days a *sine qua non*) recommendation would be a good person and a pleasing countenance; thirdly, on the direct evidence of Aubrey, who assures us that William Shakspeare was a handsome and a well-shaped man; fourthly, on the implicit evidence of the Stratford monument, which exhibits a man of good figure and noble countenance; fifthly, on the confirmation of this evidence by the Chandos portrait, which exhibits noble features, illustrated by the utmost sweetness of expression; sixthly, on the selection of theatrical parts, which it is known that Shakspeare personated, most of them being such as required some dignity of form, viz. kings, the athletic (though aged) follower of an athletic young man, and supernatural beings. On these grounds, direct or circumstantial, we believe ourselves warranted in assuming that William Shakspeare was a handsome and even noble-looking boy. Miss Anne Hathaway had herself probably some personal attractions; and, if an indigent girl, who looked for no pecuniary advantages, would probably have been early sought in marriage. But as the daughter of "a substantial yeoman," who would expect some fortune in his daughter's suitors, she had, to speak coarsely, a little outlived her market. Time she had none to lose. William Shakspeare pleased her eye; and the gentleness of his nature made him an apt subject for female blandishments, possibly for female arts. Without imputing, however, to this Anne Hathaway any thing so hateful as a settled plot for ensnaring him, it was easy enough for a mature woman, armed with such inevitable advantages of experience and of self-possession, to draw onward a blushing novice; and, without directly creating opportunities, to place him in the way of turning to account such as naturally offered. Young boys are generally flattered by the condescending notice of grown-up women; and perhaps Shakspeare's own lines upon a similar situation, to a young boy adorned with the same natural gifts as himself, may give us the key to the result:

> Gentle thou art, and therefore to be won;
> Beauteous thou art, therefore to be assail'd;
> And, when a woman woos, what woman's son
> Will sourly leave her till he have prevail'd?

Once, indeed, entangled in such a pursuit, any person of manly feelings would be sensible that he had no retreat: *that* would be—to insult a woman, grievously to wound her sexual pride, and to insure her lasting scorn and hatred. These were consequences which the gentle-minded Shakspeare could not face: he pursued his good fortunes, half perhaps in heedlessness, half in desperation, until he was roused by the clamorous displeasure of her family upon first discovering the situation of their kinswoman. For such a situation there could be but one atonement, and that was hurried forward by both parties; whilst, out of delicacy towards the bride, the wedding was not celebrated in Stratford (where the register contains no notice of such an event); nor, as Malone imagined, in Weston-upon-Avon, that being in the diocese of Gloucester; but in some parish, as yet undiscovered, in the diocese of Worcester.

But now arose a serious question as to the future maintenance of the young people. John Shakspeare was depressed in his circumstances, and he had other children besides William, viz. three sons and a daughter. The elder lives have represented him as burdened with ten; but this was an error, arising out of the confusion between John Shakspeare the glover and John Shakspeare a shoemaker. This error has been thus far of use, that, by exposing the fact of two John Shakspeares (not kinsmen) residing in Stratford-upon-Avon, it has satisfactorily proved the name to be amongst those which are locally indigenous to Warwickshire. Meantime it is now ascertained that John Shakspeare the glover had only eight children, viz. four daughters and four sons. The order of their succession was this: Joan, Margaret, WILLIAM, Gilbert, a second Joan, Anne, Richard, and Edmund. Three of the daughters, viz. the two eldest of the family, Joan and Margaret, together with Anne, died in childhood: all the rest attained mature ages, and of these William was the eldest. This might give him some advantage in his father's regard; but in a question of pecuniary provision precedency amongst the children of an insolvent is nearly nominal. For the present John Shakspeare could do little for his son; and, under these circumstances, perhaps the father of Anne Hathaway would come forward to assist the new-married couple. This condition

of dependency would furnish matter for painful feelings and irritating words: the youthful husband, whose mind would be expanding as rapidly as the leaves and blossoms of spring-time in polar latitudes, would soon come to appreciate the sort of wiles by which he had been caught. The female mind is quick, and almost gifted with the power of witchcraft, to decipher what is passing in the thoughts of familiar companions. Silent and forbearing as William Shakspeare might be, Anne, his staid wife, would read his secret reproaches; ill would she dissemble her wrath, and the less so from the consciousness of having deserved them. It is no uncommon case for women to feel anger in connection with one subject, and to express it in connection with another; which other, perhaps (except as a serviceable mask), would have been a matter of indifference to their feelings. Anne would therefore reply to those inevitable reproaches which her own sense must presume to be lurking in her husband's heart, by others equally stinging, on his inability to support his family, and on his obligations to her father's purse. Shakspeare, we may be sure, would be ruminating every hour on the means of his deliverance from so painful a dependency; and at length, after four years' conjugal discord, he would resolve upon that plan of solitary emigration to the metropolis, which, at the same time that it released him from the humiliation of domestic feuds, succeeded so splendidly for his worldly prosperity, and with a train of consequences so vast for all future ages.

Such, we are persuaded, was the real course of Shakspeare's transition from school-boy pursuits to his public career: and upon the known temperament of Shakspeare, his genial disposition to enjoy life without disturbing his enjoyment by fretting anxieties, we build the conclusion, that had his friends furnished him with ampler funds, and had his marriage been well assorted or happy, we—the world of posterity—should have lost the whole benefit and delight which we have since reaped from his matchless faculties. The motives which drove him *from* Stratford are clear enough; but what motives determined his course *to* London, and especially to the stage, still remains to be explained. Stratford-upon-Avon, lying in the high road from London through Oxford to Birmingham (or more generally to the north), had been continually visited by some of the best comedians during Shakspeare's childhood. One or two of the most respectable metropolitan actors were natives of Stratford. These would be well known to the elder Shakspeare. But, apart from that accident, it is notorious that mere legal necessity and usage would compel all companies of actors, upon coming into any town, to seek, in the first place, from the chief magistrate, a license for opening a theatre, and next, over and above this public sanction, to seek his personal favour and patronage. As an alderman, therefore, but still more whilst clothed with the official powers of chief magistrate, the poet's father would have opportunities of doing essential services to many persons connected with the London stage. The conversation of comedians acquainted with books, fresh from the keen and sparkling circles of the metropolis, and filled with racy anecdotes of the court, as well as of public life generally, could not but have been fascinating by comparison with the stagnant society of Stratford. Hospitalities on a liberal scale would be offered to these men: not impossibly this fact might be one principal key to those dilapidations which the family estate had suffered. These actors, on *their* part, would retain a grateful sense of the kindness they had received, and would seek to repay it to John Shakspeare, now that he was depressed in his fortunes, as opportunities might offer. His eldest son, growing up a handsome young man, and beyond all doubt from his earliest days of most splendid colloquial powers (for assuredly of *him* it may be taken for granted,

Nec licuit populis parvum te, Nile, videre),

would be often reproached in a friendly way for burying himself in a country life. These overtures, prompted alike by gratitude to the father, and a real selfish interest in the talents of the son, would at length take a definite shape; and, upon some clear understanding as to the terms of such an arrangement, William Shakspeare would at length (about 1586, according to the received account, that is, in the fifth year of his married life, and the twenty-third or twenty-fourth of his age), unaccompanied by wife or children, translate himself to London. Later than 1586 it could not well be; for already in 1589 it has been recently ascertained that he held a share in the property of a leading theatre.

We must here stop to notice, and the reader will allow us to notice with summary indignation, the slanderous and idle tale which represents Shakspeare as having fled to London in the character of a criminal, from the persecutions of Sir Thomas Lucy of Charlecot. This tale has long been propagated under two separate impulses: chiefly, perhaps, under the vulgar love of pointed and glaring contrasts; the splendour of the man was in this instance brought into a sort of epigrammatic antithesis with the humility of his fortunes; secondly, under a baser impulse, the malicious pleasure of seeing a great man degraded. Accordingly, as in the case of Milton,[1] it has been affirmed that Shakspeare had suffered corporal chastisement, in fact (we abhor to utter such words), that he had been judicially whipped. Now, first of all, let us mark the inconsistency of this tale: the poet was whipped, that is, he was punished most disproportionately, and yet he fled to avoid punishment. Next, we are informed that his offence was deer-stealing, and from the park of Sir Thomas Lucy. And it has been well ascertained that Sir Thomas had no deer, and had no park. Moreover, deer-stealing was regarded by our ancestors exactly as poaching is regarded by us. Deer ran wild in all the great forests; and no offence was looked upon as so venial, none so compatible with a noble Robin-Hood style of character, as this very trespass upon what were regarded as *feræ naturæ*, and not at all as domestic property. But had it been otherwise, a trespass was not punishable with whipping; nor had Sir Thomas Lucy the power to irritate a whole community like Stratford-upon-Avon, by branding with permanent disgrace a young man so closely connected with three at least of the best families in the neighbourhood. Besides, had Shakspeare suffered any dishonour of that kind, the scandal would infallibly have pursued him at his very heels to Lon-

[1] In a little memoir of Milton, which the author of this article drew up some years ago for a public society, and which is printed in an abridged shape, he took occasion to remark, that Dr Johnson, who was meanly anxious to revive this slander against Milton, as well as some others, had supposed Milton himself to have this flagellation in his mind, and indirectly to confess it, in one of his Latin poems, where, speaking of Cambridge, and declaring that he has no longer any pleasure in the thoughts of revisiting that university, he says,

"Nec duri libet usque minas perferre magistri,
Cæteraque ingenio non subeunda meo."

This last line the malicious critic would translate—"And other things insufferable to a man of my temper." But, as we then observed, *ingenium* is properly expressive of the *intellectual* constitution, whilst it is the *moral* constitution that suffers degradation from personal chastisement—the sense of honour, of personal dignity, of justice, &c. *Indoles* is the proper term for this latter idea; and in using the word *ingenium*, there cannot be a doubt that Milton alluded to the dry scholastic disputations, which were shocking and odious to his fine poetical genius. If, therefore, the vile story is still to be kept up in order to dishonour a great man, at any rate let it not in future be pretended that any countenance to such a slander can be drawn from the confessions of the poet himself.

don; and in that case Greene, who has left on record, in a posthumous work of 1592, his malicious feelings towards Shakspeare, could not have failed to notice it. For, be it remembered, that a judicial flagellation contains a twofold ignominy: flagellation is ignominious in its own nature, even though unjustly inflicted, and by a ruffian; secondly, any judicial punishment is ignominious, even though not wearing a shade of personal degradation. Now a judicial flagellation includes both features of dishonour. And is it to be imagined that an enemy, searching with the diligence of malice for matter against Shakspeare, should have failed, six years after the event, to hear of that very memorable disgrace which had exiled him from Stratford, and was the very occasion of his first resorting to London; or that a leading company of players in the metropolis, *one of whom*, and a chief one, *was his own townsman*, should cheerfully adopt into their society, as an honoured partner, a young man yet flagrant from the lash of the executioner or the beadle?

This tale is fabulous, and rotten to its core; yet even this does less dishonour to Shakspeare's memory than the sequel attached to it. A sort of scurrilous rondeau, consisting of nine lines, so loathsome in its brutal stupidity, and so vulgar in its expression, that we shall not pollute our pages by transcribing it, has been imputed to Shakspeare ever since the days of the credulous Rowe. The total point of this idiot's drivel consists in calling Sir Thomas "an asse;" and well it justifies the poet's own remark, "Let there be gall enough in thy ink, no matter though thou write with a goose pen." Our own belief is, that these lines were a production of Charles II.'s reign, and applied to a Sir Thomas Lucy, not very far removed, if at all, from the age of him who first picked up the precious filth: the phrase "parliament *member*," we believe to be quite unknown in the colloquial use of Queen Elizabeth's reign.

But, that we may rid ourselves once and for ever of this outrageous calumny upon Shakspeare's memory, we shall pursue the story to its final stage. Even Malone has been thoughtless enough to accredit this closing chapter, which contains, in fact, such a superfetation of folly as the annals of human dulness do not exceed. Let us recapitulate the points of the story. A baronet, who has no deer and no park, is supposed to persecute a poet for stealing these aerial deer out of this aerial park, both lying in *nephelococcygia*. The poet sleeps upon this wrong for eighteen years; but at length, hearing that his persecutor is dead and buried, he conceives bloody thoughts of revenge. And this revenge he purposes to execute by picking a hole in his dead enemy's coat-of-arms. Is this coat-of-arms, then, Sir Thomas Lucy's? Why, no: Malone admits that it is not. For the poet, suddenly recollecting that this ridicule would settle upon the son of his enemy, selects another coat-of-arms, with which his dead enemy never had any connection, and he spends his thunder and lightning upon this irrelevant object; and, after all, the ridicule itself lies in a Welchman's mispronouncing one single heraldic term—a Welchman who mispronounces all words. The last act of the poet's malice recalls to us a sort of jest-book story of an Irishman, the vulgarity of which the reader will pardon in consideration of its relevancy. The Irishman having lost a pair of silk stockings, mentions to a friend that he has taken steps for recovering them by an advertisement, offering a reward to the finder. His friend objects that the costs of advertising, and the reward, would eat out the full value of the silk stockings. But to this the Irishman replies, with a knowing air, that he is not so green as to have overlooked *that;* and that, to keep down the reward, he had advertised the stockings as worsted. Not at all less flagrant is the bull ascribed to Shakspeare, when he is made to punish a dead man by personalities meant for his exclusive ear, through his coat-of-arms, but at the same time, with the express purpose of blunting and defeating the edge of his own scurrility, is made to substitute for the real arms some others which had no more relation to the dead enemy than they had to the poet himself. This is the very sublime of folly, beyond which human dotage cannot advance.

It is painful, indeed, and dishonourable to human nature, that whenever men of vulgar habits and of poor education wish to impress us with a feeling of respect for a man's talents, they are sure to cite, by way of evidence, some gross instance of malignity. Power, in their minds, is best illustrated by malice or by the infliction of pain. To this unwelcome fact we have some evidence in the wretched tale which we have just dismissed; and there is another of the same description to be found in all lives of Shakspeare, which we will expose to the contempt of the reader whilst we are in this field of discussion, that we may not afterwards have to resume so disgusting a subject.

This poet, who was a model of gracious benignity in his manners, and of whom, amidst our general ignorance, thus much is perfectly established, that the term *gentle* was almost as generally and by prescriptive right associated with his name as the affix of *venerable* with Bede, or *judicious* with Hooker, is alleged to have insulted a friend by an imaginary epitaph beginning "*Ten in the Hundred*," and supposing him to be damned, yet without wit enough (which surely the Stratford bellman could have furnished) for devising any, even fanciful, reason for such a supposition; upon which the comment of some foolish critic is, "The *sharpness of the satire* is said to have stung the man so much that he never forgave it." We have heard of the sting in the tail atoning for the brainless head; but in this doggerel the tail is surely as stingless as the head is brainless. For, 1*st*, *Ten in the Hundred* could be no reproach in Shakspeare's time, any more than to call a man *Three-and-a-half-per-cent.* in this present year 1838; except, indeed, amongst those foolish persons who built their morality upon the Jewish ceremonial law. Shakspeare himself took ten per cent. 2*dly*, It happens that John Combe, so far from being the object of the poet's scurrility, or viewing the poet as an object of implacable resentment, was a Stratford friend; that one of his family was affectionately remembered in Shakspeare's will by the bequest of his sword; and that John Combe himself recorded his perfect charity with Shakspeare by leaving him a legacy of L.5 sterling. And in this lies the key to the whole story. For, 3*dly*, the four lines were written and printed before Shakspeare was born. The name Combe is a common one; and some stupid fellow, who had seen the name in Shakspeare's will, and happened also to have seen the lines in a collection of epigrams, chose to connect the cases by attributing an identity to the two John Combes, though at war with chronology.

Finally, there is another specimen of doggerel attributed to Shakspeare, which is not equally unworthy of him, because not equally malignant, but otherwise equally below his intellect, no less than his scholarship; we mean the inscription on his grave-stone. This, as a sort of *siste viator* appeal to future sextons, is worthy of the grave-digger or the parish-clerk, who was probably its author. Or it may have been an antique formula, like the vulgar record of ownership in books—

Anthony Timothy Dolthead's book,
God give him grace therein to look.

Thus far the matter is of little importance; and it might have been supposed that malignity itself could hardly have imputed such trash to Shakspeare. But when we find, even in this short compass, scarcely wider than the posy of a ring, room found for traducing the poet's memory, it becomes important to say, that the leading sentiment, the

horror expressed at any disturbance offered to his bones, is not one to which Shakspeare could have attached the slightest weight; far less could have outraged the sanctities of place and subject, by affixing to any sentiment whatever (and, according to the fiction of the case, his farewell sentiment) the sanction of a curse.

Filial veneration and piety towards the memory of this great man have led us into a digression that might have been unseasonable in any cause less weighty than one having for its object to deliver his honoured name from a load of the most brutal malignity. Never more, we hope and venture to believe, will any thoughtless biographer impute to Shakspeare the asinine doggerel with which the uncritical blundering of his earliest biographer has caused his name to be dishonoured. We now resume the thread of our biography. The stream of history is centuries in working itself clear of any calumny with which it has once been polluted.

Most readers will be aware of an old story, according to which Shakspeare gained his livelihood for some time after coming to London by holding the horses of those who rode to the play. This legend is as idle as any one of those which we have just exposed. No custom ever existed of riding on horseback to the play. Gentlemen, who rode valuable horses, would assuredly not expose them systematically to the injury of standing exposed to cold for two or even four hours; and persons of inferior rank would not ride on horseback in the town. Besides, had such a custom ever existed, stables (or sheds at least) would soon have arisen to meet the public wants; and in some of the dramatic sketches of the day, which noticed every fashion as it arose, this would not have been overlooked. The story is traced originally to Sir William Davenant. Betterton the actor, who professed to have received it from him, passed it onwards to Rowe, he to Pope, Pope to Bishop Newton the editor of Milton, and Newton to Dr Johnson. This pedigree of the fable, however, adds nothing to its credit, and multiplies the chances of some mistake. Another fable, not much less absurd, represents Shakspeare as having from the very first been borne upon the establishment of the theatre, and so far contradicts the other fable, but originally in the very humble character of *call-boy* or deputy prompter, whose business it was to summon each performer according to his order of coming upon the stage. This story, however, quite as much as the other, is irreconcileable with the discovery recently made by Mr Collier, that in 1589 Shakspeare was a shareholder in the important property of a principal London theatre. It seems destined that all the undoubted facts of Shakspeare's life should come to us through the channel of legal documents, which are better evidence even than imperial medals; whilst, on the other hand, all the fabulous anecdotes, not having an attorney's seal to them, seem to have been the fictions of the wonder-maker. The plain presumption from the record of Shakspeare's situation in 1589, coupled with the fact that his first arrival in London was possibly not until 1587, but according to the earliest account not before 1586, a space of time which leaves but little room for any remarkable changes of situation, seems to be, that, either in requital of services done to the players by the poet's family, or in consideration of money advanced by his father-in-law, or on account of Shakspeare's personal accomplishments as an actor, and as an adapter of dramatic works to the stage; for one of these reasons, or for all of them united, William Shakspeare, about the 23d year of his age, was adopted into the partnership of a respectable histrionic company, possessing a first-rate theatre in the metropolis. If 1586 were the year in which he came up to London, it seems probable enough that his immediate motive to that step was the increasing distress of his father; for in that year John Shakspeare resigned the office of alderman. There is, however, a bare possibility that Shakspeare might have gone to London about the time when he completed his twenty-first year, that is, in the spring of 1585, but not earlier. Nearly two years after the birth of his eldest daughter Susanna, his wife lay in for a second and a *last* time; but she then brought her husband twins, a son and a daughter. These children were baptized in February of the year 1585; so that Shakspeare's whole family of three children were born and baptized two months before he completed his majority. The twins were baptized by the names of Hamnet and Judith, those being the names of two amongst their sponsors, viz. Mr Sadler and his wife. Hamnet, which is a remarkable name in itself, becomes still more so from its resemblance to the immortal name of Hamlet[1] the Dane; it was, however, the real baptismal name of Mr Sadler, a friend of Shakspeare's, about fourteen years older than himself. Shakspeare's son must then have been most interesting to his heart, both as a twin child and as his only boy. He died in 1596, when he was about eleven years old. Both daughters survived their father; both married; both left issue, and thus gave a chance for continuing the succession from the great poet. But all the four grandchildren died without offspring.

Of Shakspeare personally, at least of Shakspeare the man, as distinguished from the author, there remains little more to record. Already in 1592, Greene, in his posthumous Groat's-worth of Wit, had expressed the earliest vocation of Shakspeare in the following sentence:—"There is an upstart crow, beautified with our feathers; in his own conceit the only *Shakscene* in a country!" This alludes to Shakspeare's office of re-casting, and even re-composing, dramatic works, so as to fit them for representation; and Master Greene, it is probable, had suffered in his self-estimation, or in his purse, by the alterations in some piece of his own which the duty of Shakspeare to the general interests of the theatre had obliged him to make. In 1591 it has been supposed that Shakspeare wrote his first drama, the Two Gentlemen of Verona; the least characteristically marked of all his plays, and, with the exception of Love's Labour's Lost, the least interesting.

From this year, 1591 to that of 1611, are just twenty years, within which space lie the whole dramatic creations of Shakspeare, averaging nearly one for every six months. In 1611 was written the Tempest, which is supposed to have been the last of all Shakspeare's works. Even on that account, as Mr Campbell feelingly observes, it has "a sort of sacredness;" and it is a most remarkable fact, and one calculated to make a man superstitious, that in this play the great enchanter Prospero, in whom, "*as if conscious*," says Mr Campbell, "*that this would be his last work*, the poet has been *inspired to typify himself as* a wise, potent, and *benevolent magician*," of whom, indeed, as of Shakspeare himself, it may be said, that "within that circle" (the circle of his own art) "none durst tread but he," solemnly and for ever renounces his mysterious functions, symbolically breaks his enchanter's wand, and declares that he will bury his books, his science, and his secrets

Deeper than did ever plummet sound.

Nay, it is even ominous, that in this play, and from the

[1] And singular enough it is, as well as interesting, that Shakspeare had so entirely superseded to his own ear and memory the name Hamnet by the dramatic name of Hamlet, that in writing his will, he actually mis-spells the name of his friend Sadler, and calls him Hamlet. His son, however, who should have familiarized the true name to his ear, had then been dead for twenty years.

Shakspeare. voice of Prospero, issues that magnificent prophecy of the total destruction which should one day swallow up

> The solemn temples, the great globe itself,
> Yea all which it inherit.

And this prophecy is followed immediately by a most profound ejaculation, gathering into one pathetic abstraction the total philosophy of life:

> We are such stuff
> As dreams are made of; and our little life
> Is rounded by a sleep;

that is, in effect, our life is a little tract of feverish vigils, surrounded and islanded by a shoreless ocean of sleep—sleep before birth, sleep after death.

These remarkable passages were probably not undesigned; but if we suppose them to have been thrown off without conscious notice of their tendencies, then, according to the superstition of the ancient Grecians, they would have been regarded as prefiguring words, prompted by the secret genius that accompanies every man, such as insure along with them their own accomplishment. With or without intention, however, it is believed that Shakspeare wrote nothing more after this exquisite romantic drama. With respect to the remainder of his personal history, Dr Drake and others have supposed, that during the twenty years from 1591 to 1611, he visited Stratford often, and latterly once a year.

In 1589 he had possessed some share in a theatre; in 1596 he had a considerable share. Through Lord Southampton, as a surviving friend of Lord Essex, who was viewed as the martyr to his Scottish politics, there can be no doubt that Shakspeare had acquired the favour of James I.; and accordingly, on the 29th of May 1603, about two months after the king's accession to the throne of England, a patent was granted to the company of players who possessed the Globe theatre; in which patent Shakspeare's name stands second. This patent raised the company to the rank of his majesty's servants, whereas previously they are supposed to have been simply the servants of the Lord Chamberlain. Perhaps it was in grateful acknowledgment of this royal favour that Shakspeare afterwards, in 1606, paid that sublime compliment to the house of Stuart which is involved in the vision shown to Macbeth. This vision is managed with exquisite skill: it was impossible to display the whole series of princes from Macbeth to James I.; but he beholds the posterity of Banquo, one "gold-bound brow" succeeding to another, until he comes to an eighth apparition of a Scottish king,

> Who bears a glass
> Which shows him many more; and some he sees
> Who *twofold* balls and *treble* sceptres carry;

thus bringing down without tedium the long succession to the very person of James I. by the symbolic image of the two crowns united on one head.

About the beginning of the century Shakspeare had become rich enough to purchase the best house in Stratford, called *The Great House*, which name he altered to *New Place;* and in 1602 he bought 107 acres adjacent to this house for a sum (L.320) corresponding to about 1500 guineas of modern money. Malone thinks that he purchased the house as early as 1597; and it is certain that about that time he was able to assist his father in obtaining a renewed grant of arms from the Heralds' College, and therefore, of course, to re-establish his father's fortunes. Ten years of well-directed industry, viz. from 1591 to 1601, and the prosperity of the theatre in which he was a proprietor, had raised him to affluence; and after another ten years, improved with the same success, he was able to retire with an income of L.300, or (according to the customary computations) in modern money of L.1500, per annum. Shakspeare was in fact the first man of letters, Pope the second, and Sir Walter Scott the third, who, in Great Britain, has ever realized a large fortune by literature; or in Christendom, if we except Voltaire, and two dubious cases in Italy. The four or five latter years of his life Shakspeare passed in dignified ease, in profound meditation, we may be sure, and in universal respect, at his native town of Stratford; and there he died, on the 23d of April 1616.[1]

His daughter Susanna had been married on the 5th of June of the year 1607, to Dr John Hall,[2] a physician in Stratford. The doctor died in November 1635, aged sixty; his wife, at the age of sixty-six, on July 11, 1640. They had one child, a daughter, named Elizabeth, born in 1608, married April 22, 1626, to Thomas Nashe, Esq. left a widow in 1647, and subsequently remarried to Sir John Barnard; but this Lady Barnard, the sole grand-daughter of the poet, had no children by either marriage. The other daughter Judith, on February 10, 1616 (about ten weeks before her father's death) married Mr Thomas Quiney of Stratford, by whom she had three sons, Shakspeare, Richard, and Thomas. Judith was about thirty-one years old at the time of her marriage; and living just forty-six years afterwards, she died in February 1662, at the age of seventy-seven. Her three sons died without issue; and thus, in the direct lineal descent, it is certain that no representative has survived of this transcendent poet, the most august amongst created intellects.

After this review of Shakspeare's life, it becomes our duty to take a summary survey of his works, of his intellectual powers, and of his station in literature, a station which is now irrevocably settled, not so much (which happens in other cases) by a vast overbalance of favourable suffrages, as by acclamation; not so much by the *voices* of those who admire him up to the verge of idolatry, as by the *acts* of those who everywhere seek for his works among the primal necessities of life, demand them, and crave them as they do their daily bread; not so much by eulogy openly proclaiming itself, as by the silent homage recorded in the endless multiplication of what he has bequeathed us; not so much by his own compatriots, who, with regard to almost every other author,[3] compose the total amount of his

[1] "I have heard that Mr Shakspeare was a natural wit, without any art at all. Hee frequented the plays all his younger time, but in his elder days lived at Startford, and supplied the stage with two plays every year, and for itt had an allowance so large, that he spent at the rate of 1,000*l.* a-year, as I have heard. Shakespeare, Drayton, and Ben Jonson, had a merie meeting, and it seems drank too hard, for Shakespear died of a feavour there contracted." (Diary of the Rev. John Ward, A. M. Vicar of Stratford-upon-Avon, extending from 1648 to 1679, p. 183. Lond. 1839, 8vo.)

[2] It is naturally to be supposed that Dr Hall would attend the sick-bed of his father-in-law; and the discovery of this gentleman's medical diary promised some gratification to our curiosity as to the cause of Shakspeare's death. Unfortunately, it does not commence until the year 1617.

[3] An exception ought perhaps to be made for Sir Walter Scott and for Cervantes; but with regard to all other writers, Dante, suppose, or Ariosto amongst Italians, Camoens amongst those of Portugal, Schiller amongst Germans, however ably they may have been naturalized in foreign languages, as all of those here mentioned (excepting only Ariosto) have in one part of their works been most powerfully naturalized in English, it still remains true (and the very sale of the books is proof sufficient) that an alien author never does take root in the general sympathies out of his own country; he takes his station in libraries, he is read by the man of learned leisure, he is known and valued by the refined and the elegant, but he is not (what Shakspeare is for Germany and America in any proper sense a *popular* favourite.

effective audience, as by the unanimous "all hail!" of intellectual Christendom; finally, not by the hasty partisanship of his own generation, nor by the biassed judgment of an age trained in the same modes of feeling and of thinking with himself, but by the solemn award of generation succeeding to generation, of one age correcting the obliquities or peculiarities of another; by the verdict of two hundred and thirty years, which have now elapsed since the very *latest* of his creations, or of two hundred and forty-seven years if we date from the earliest; a verdict which has been continually revived and re-opened, probed, searched, vexed, by criticism in every spirit, from the most genial and intelligent, down to the most malignant and scurrilously hostile which feeble heads and great ignorance could suggest when co-operating with impure hearts and narrow sensibilities; a verdict, in short, sustained and countersigned by a longer series of writers, many of them eminent for wit or learning, than were ever before congregated upon any inquest relating to any author, be he who he might, ancient[1] or modern, Pagan or Christian. It was a most witty saying with respect to a piratical and knavish publisher, who made a trade of insulting the memories of deceased authors by forged writings, that he was "among the new terrors of death." But in the gravest sense it may be affirmed of Shakspeare, that he is among the modern luxuries of life; that life, in fact, is a new thing, and one more to be coveted, since Shakspeare has extended the domains of human consciousness, and pushed its dark frontiers into regions not so much as dimly descried or even suspected before his time, far less illuminated (as now they are) by beauty and tropical luxuriance of life. For instance,—a single instance, indeed one which in itself is a world of new revelation,—the possible beauty of the female character had not been seen as in a dream before Shakspeare called into perfect life the radiant shapes of Desdemona, of Imogene, of Hermione, of Perdita, of Ophelia, of Miranda, and many others. The Una of Spenser, earlier by ten or fifteen years than most of these, was an idealized portrait of female innocence and virgin purity, but too shadowy and unreal for a dramatic reality. And as to the Grecian classics, let not the reader imagine for an instant that any prototype in this field of Shakspearian power can be looked for there. The *Antigone* and the *Electra* of the tragic poets are the two leading female characters that classical antiquity offers to our respect, but assuredly not to our impassioned love, as disciplined and exalted in the school of Shakspeare. They challenge our admiration, severe, and even stern, as impersonations of filial duty, cleaving to the steps of a desolate and afflicted old man; or of sisterly affection, maintaining the rights of a brother under circumstances of peril, of desertion, and consequently of perfect self-reliance. Iphigenia, again, though not dramatically coming before us in her own person, but according to the beautiful report of a spectator, presents us with a fine statuesque model of heroic fortitude, and of one whose young heart, even in the very agonies of her cruel immolation, refused to forget, by a single indecorous gesture, or so much as a moment's neglect of her own princely descent, and that she herself was "a lady in the land." These are fine marble groups, but they are not the warm breathing realities of Shakspeare; there is "no speculation" in their cold marble eyes; the breath of life is not in their nostrils; the fine pulses of womanly sensibilities are not throbbing in their bosoms. And besides this immeasurable difference between the cold moony reflexes of life, as exhibited by the power of Grecian art, and the true sunny life of Shakspeare, it must be observed that the Antigones, &c. of the antique put forward but one single trait of character, like the aloe with its single blossom: this solitary feature is presented to us as an abstraction, and as an insulated quality; whereas in Shakspeare all is presented in the *concrete;* that is to say, not brought forward in relief, as by some effort of an anatomical artist; but embodied and imbedded, so to speak, as by the force of a creative nature, in the complex system of a human life; a life in which all the elements move and play simultaneously, and with something more than mere simultaneity or co-existence, acting and re-acting each upon the other, nay, even acting by each other and through each other. In Shakspeare's characters is felt for ever a real *organic* life, where each is for the whole and in the whole, and where the whole is for each and in each. They only are real incarnations.

The Greek poets could not exhibit any approximations to *female* character, without violating the truth of Grecian life, and shocking the feelings of the audience. The drama with the Greeks, as with us, though much less than with us, was a picture of human life; and that which could not occur in life could not wisely be exhibited on the stage. Now, in ancient Greece, women were secluded from the society of men. The conventual sequestration of the γυναικωνῖτις, or female apartment[2] of the house, and the Mahommedan consecration of its threshold against the ingress of males, had been transplanted from Asia into Greece thousands of years perhaps before either convents or Mahommed existed. Thus barred from all open social intercourse, women could not develope or express any character by word or action. Even to *have* a character, violated, to a Grecian mind, the ideal portrait of feminine excellence; whence, perhaps, partly the too generic, too little individualized, style of Grecian beauty. But prominently to *express* a character was impossible under the common tenor of Grecian life, unless when high tragical catastrophes transcended the decorums of that tenor, or for a brief interval raised the curtain which veiled it. Hence the subordinate part which women play upon the Greek stage in all but some half dozen cases. In the paramount tragedy on that stage, the model tragedy, the *Œdipus Tyrannus* of Sophocles, there is virtually no woman at all; for Jocasta is a party to the story merely as the dead Laius or the self-murdered Sphinx was a party, viz. by her contributions to the fatalities of the event, not by any thing she does or says spontaneously. In fact, the

[1] It will occur to many readers, that perhaps Homer may furnish the sole exception to this sweeping assertion: any *but* Homer is clearly and ludicrously below the level of the competition; but even Homer, "with his tail on" (as the Scottish Highlanders say of their chieftains when belted by their ceremonial retinues), musters nothing like the force which *already* follows Shakspeare; and be it remembered, that Homer sleeps and has long slept as a subject of criticism or commentary, while in Germany as well as England, and *now even in France*, the gathering of wits to the vast equipage of Shakspeare is advancing in an accelerated ratio. There is, in fact, a great delusion current upon this subject. Innumerable references to Homer, and brief critical remarks on this or that pretension of Homer, this or that scene, this or that passage, lie scattered over literature ancient and modern; but the express works dedicated to the separate service of Homer are, after all, not many. In Greek we have only the large Commentary of Eustathius, and the Scholia of Didymus, &c.; in French little or nothing before the prose translation of the seventeenth century, which Pope esteemed "elegant," and the skirmishings of Madame Dacier, La Motte, &c.; in English, besides the various translations and their prefaces (which, by the way, began as early as 1555), nothing of much importance until the elaborate preface of Pope to the Iliad, and his elaborate postscript to the Odyssey—nothing certainly before that, and very little indeed since that, except Wood's Essay on the Life and Genius of Homer. On the other hand, of the books written in illustration or investigation of Shakspeare, a very considerable library might be formed in England, and another in Germany.

[2] Apartment is here used, as the reader will observe, in its true and continental acceptation, as a division or *compartment* of a house including many rooms; a suite of chambers, but a suite which is partitioned off (as in palaces), not a single chamber; a sense so commonly and so erroneously given to this word in England.

Shakspeare.

Greek poet, if a wise poet, could not address himself genially to a task in which he must begin by shocking the sensibilities of his countrymen. And hence followed, not only the dearth of female characters in the Grecian drama, but also a second result still more favourable to the sense of a new power evolved by Shakspeare. Whenever the common law of Grecian life did give way, it was, as we have observed, to the suspending force of some great convulsion or tragical catastrophe. This for a moment (like an earthquake in a nunnery) would set at liberty even the timid, fluttering Grecian women, those doves of the dove-cot, and would call some of them into action. But which? Precisely those of energetic and masculine minds; the timid and feminine would but shrink the more from public gaze and from tumult. Thus it happened, that such female characters as *were* exhibited in Greece, could not but be the harsh and the severe. If a gentle Ismene appeared for a moment in contest with some energetic sister Antigone (and chiefly, perhaps, by way of drawing out the fiercer character of that sister), she was soon dismissed as unfit for scenical effect. So that not only were female characters few, but, moreover, of these few the majority were but repetitions of masculine qualities in female persons. Female agency being seldom summoned on the stage except when it had received a sort of special dispensation from its sexual character, by some terrific convulsions of the house or the city, naturally it assumed the style of action suited to these circumstances. And hence it arose, that not woman as she differed from man, but woman as she resembled man—woman, in short, seen under circumstances so dreadful as to abolish the effect of sexual distinction, was the woman of the Greek tragedy.[1] And hence generally arose for Shakspeare the wider field, and the more astonishing by its perfect novelty, when he first introduced female characters, not as mere varieties or echoes of masculine characters, a Medea or Clytemnestra, or a vindictive Hecuba, the mere tigress of the tragic tiger, but female characters that had the appropriate beauty of female nature; woman no longer grand, terrific, and repulsive, but woman "after her kind"—the other hemisphere of the dramatic world; woman running through the vast gamut of womanly loveliness; woman as emancipated, exalted, ennobled, under a new law of Christian morality; woman the sister and co-equal of man, no longer his slave, his prisoner, and sometimes his rebel. "It is a far cry to Loch Awe;" and from the Athenian stage to the stage of Shakspeare, it may be said, is a prodigious interval. True; but prodigious as it is, there is really nothing between them. The Roman stage, at least the tragic stage, as is well known, was put out, as by an extinguisher, by the cruel amphitheatre, just as a candle is made pale and ridiculous by daylight. Those who were fresh from the real murders of the bloody amphitheatre regarded with contempt the mimic murders of the stage. Stimulation too coarse and too intense had its usual effect in making the sensibilities callous. Christian emperors arose at length, who abolished the amphitheatre in its bloodier features. But by that time the genius of the tragic muse had long slept the sleep of death. And that muse had no resurrection until the age of Shakspeare. So that, notwithstanding a gulf of nineteen centuries and upwards separates Shakspeare from Euripides, the last of the surviving Greek tragedians, the one is still the nearest successor of the other, just as Connaught and the islands in Clew Bay are next neighbours to America, although three thousand watery columns, each of a cubic mile in dimensions, divide them from each other.

A second reason, which lends an emphasis of novelty and effective power to Shakspeare's female world, is a peculiar fact of contrast which exists between that and his corresponding world of men. Let us explain. The purpose and the intention of the Grecian stage was not primarily to develope human *character*, whether in men or in women; human *fates* were its object; great tragic situations under the mighty control of a vast cloudy destiny, dimly descried at intervals, and brooding over human life by mysterious agencies, and for mysterious ends. Man, no longer the representative of an august *will*, man the passion-puppet of fate, could not with any effect display what we call a character, which is a distinction between man and man, emanating originally from the will, and expressing its determinations, moving under the large variety of human impulses. The will is the central pivot of character; and this was obliterated, thwarted, cancelled, by the dark fatalism which brooded over the Grecian stage. That explanation will sufficiently clear up the reason why marked or complex variety of character was slighted by the great principles of the Greek tragedy. And every scholar who has studied that grand drama of Greece with feeling,—that drama, so magnificent, so regal, so stately,—and who has thoughtfully investigated its principles, and its difference from the English drama, will acknowledge that powerful and elaborate character, character, for instance, that could employ the fiftieth part of that profound analysis which has been applied to Hamlet, to Falstaff, to Lear, to Othello, and applied by Mrs Jamieson so admirably to the full development of the Shakspearian heroines, would have been as much wasted, nay, would have been defeated, and interrupted the blind agencies of fate, just in the same way as it would injure the shadowy grandeur of a ghost to individualize it too much. Milton's angels are slightly touched, superficially touched, with differences of character; but they are such differences, so simple and general, as are just sufficient to rescue them from the reproach applied to Virgil's "*fortemque Gyan, fortemque Cloanthem;*" just sufficient to make them knowable apart. Pliny speaks of painters who painted in one or two colours; and, as respects the angelic characters, Milton does so; he is *monochromatic.* So, and for reasons resting upon the same ultimate philosophy, were the mighty architects of the Greek tragedy. They also were monochromatic; they also, as to the characters of their persons, painted in one colour. And so far there might have been the same novelty in Shakspeare's men as in his women. There *might* have been; but the reason why there is *not*, must be sought in the fact, that History, the muse of History, had there even been no such muse as Melpomene, would have forced us into an acquaintance with human character. History, as the representative of actual life, of real man, gives us powerful delineations of character in its chief agents, that is, in men; and therefore it is that Shakspeare, the absolute creator of female character, was but the mightiest of all painters with regard to male character. Take a single instance. The Antony of Shakspeare, immortal for its execution, is found, after all, as regards the primary conception, in history: Shakspeare's delineation is but the expansion of the germ already pre-existing, by way of scattered fragments, in Cicero's Philippics, in Cicero's Letters, in Appian, &c. But Cleopatra, equally fine, is a pure creation of art: the situation and the scenic circumstances belong to history, but the character belongs to Shakspeare.

In the great world therefore of woman, as the interpreter of the shifting phases and the lunar varieties of that

[1] And hence, by parity of reason, under the opposite circumstances, under the circumstances which, instead of abolishing, most emphatically drew forth the sexual distinctions, viz. in the *comic* aspects of social intercourse, the reason that we see no women on the Greek stage; the Greek comedy, unless when it affects the extravagant fun of farce, rejects women.

mighty changeable planet, that lovely satellite of man, Shakspeare stands not the first only, not the original only, but is yet the sole authentic oracle of truth. Woman, therefore, the beauty of the female mind, *this* is one great field of his power. The supernatural world, the world of apparitions, *that* is another: for reasons which it would be easy to give, reasons emanating from the gross mythology of the ancients, no Grecian,[1] no Roman, could have conceived a ghost. That shadowy conception, the protesting apparition, the awful projection of the human conscience, belongs to the Christian mind: and in all Christendom, who, let us ask, who, who but Shakspeare has found the power for effectually working this mysterious mode of being? In summoning back to earth "the majesty of buried Denmark," how like an awful necromancer does Shakspeare appear! All the pomps and grandeurs which religion, which the grave, which the popular superstition had gathered about the subject of apparitions, are here converted to his purpose, and bend to one awful effect. The wormy grave brought into antagonism with the scenting of the early dawn; the trumpet of resurrection suggested, and again as an antagonist idea to the crowing of the cock (a bird ennobled in the Christian mythus by the part he is made to play at the Crucifixion); its starting "as a guilty thing" placed in opposition to its majestic expression of offended dignity when struck at by the partisans of the sentinels; its awful allusions to the secrets of its prison-house; its ubiquity, contrasted with its local presence; its aerial substance, yet clothed in palpable armour; the heart-shaking solemnity of its language, and the appropriate scenery of its haunt, viz. the ramparts of a capital fortress, with no witnesses but a few gentlemen mounting guard at the dead of night,—what a mist, what a *mirage* of vapour, is here accumulated, through which the dreadful being in the centre looms upon us in far larger proportions than could have happened had it been insulated and left naked of this circumstantial pomp! In the *Tempest*, again, what new modes of life, preternatural, yet far as the poles from the spiritualities of religion. Ariel in antithesis to Caliban! What is most ethereal to what is most animal! A phantom of air, an abstraction of the dawn and of vesper sun-lights, a bodiless sylph on the one hand; on the other a gross carnal monster, like the Miltonic Asmodai, "the fleshliest incubus" among the fiends, and yet so far ennobled into interest by his intellectual power, and by the grandeur of misanthropy![2] In the *Midsummer-Night's Dream*, again, we have the old traditional fairy, a lovely mode of preternatural life, remodified by Shakspeare's eternal talisman. Oberon and Titania remind us at first glance of Ariel: they approach, but how far they recede: they are like—"like, but, oh, how different!" And in no other exhibition of this dreamy population of the moonlight forests and forest-lawns, are the circumstantial proprieties of fairy life so exquisitely imagined, sustained, or expressed. The dialogue between Oberon and Titania is, of itself, and taken separately from its connection, one of the most delightful poetic scenes that literature affords. The witches in Macbeth are another variety of supernatural life, in which Shakspeare's power to enchant and to disenchant are alike portentous. The circumstances of the blasted heath, the army at a distance, the withered attire of the mysterious hags, and the choral litanics of their fiendish Sabbath, are as finely imagined in their kind as those which herald and which surround the ghost in Hamlet. There we see the *positive* of Shakspeare's superior power But now turn and look to the *negative*. At a time when the trials of witches, the royal book on demonology, and popular superstition (all so far useful, as they prepared a basis of undoubting faith for the poet's serious use of such agencies) had degraded and polluted the ideas of these mysterious beings by many mean associations, Shakspeare does not fear to employ them in high tragedy (a tragedy moreover which, though not the very greatest of his efforts as an intellectual whole, nor as a struggle of passion, is *among* the greatest in any view, and positively *the* greatest for scenical grandeur, and in that respect makes the nearest approach of all English tragedies to the Grecian model); he does not fear to introduce, for the same appalling effect as that for which Æschylus introduced the Eumenides, a triad of old women, concerning whom an English wit has remarked this grotesque peculiarity in the popular creed of that day,—that although potent over winds and storms, in league with powers of darkness, they yet stood in awe of the constable,—yet relying on his own supreme power to disenchant as well as to enchant, to create and to uncreate, he mixes these women and their dark machineries with the power of armies, with the agencies of kings, and the fortunes of martial kingdoms. Such was the sovereignty of this poet, so mighty its compass!

A third fund of Shakspeare's peculiar power lies in his teeming fertility of fine thoughts and sentiments. From his works alone might be gathered a golden bead-roll of thoughts the deepest, subtilest, most pathetic, and yet most catholic and universally intelligible; the most characteristic, also, and appropriate to the particular person, the situation, and the case, yet, at the same time, applicable to the circumstances of every human being, under all the accidents of life, and all vicissitudes of fortune. But this subject offers so vast a field of observation, it being so eminently the prerogative of Shakspeare to have thought more finely and more extensively than all other poets combined, that we cannot wrong the dignity of such a theme by doing more, in our narrow limits, than simply noticing it as one of the emblazonries upon Shakspeare's shield.

Fourthly, we shall indicate (and, as in the last case, *barely* indicate, without attempting in so vast a field to offer any inadequate illustrations) one mode of Shakspeare's dramatic excellence which hitherto has not attracted any special or separate notice. We allude to the forms of life, and natural human passion, as apparent in the structure of his dialogue. Among the many defects and infirmities of the

[1] It may be thought, however, by some readers, that Æschylus, in his fine phantom of Darius, has approached the English ghost. As a foreign ghost, we would wish (and we are sure that our excellent readers would wish) to show every courtesy and attention to this apparition of Darius. It has the advantage of being royal, an advantage which it shares with the ghost of the royal Dane. Yet how different, how removed by a total world, from that or any of Shakspeare's ghosts! Take that of Banquo, for instance: how shadowy, how unreal, yet how real! Darius is a mere state ghost—a diplomatic ghost. But Banquo—he exists only for Macbeth; the guests do not see him, yet how solemn, how real, how heart-searching he is.

[2] Caliban has not yet been thoroughly fathomed. For all Shakspeare's great creations are like works of nature, subjects of unexhaustible study. It was this character of whom Charles I. and some of his ministers expressed such fervent admiration; and, among other circumstances, most justly they admired the new language almost with which he is endowed, for the purpose of expressing his fiendish and yet carnal thoughts of hatred to his master. Caliban is evidently not meant for scorn, but for abomination mixed with fear and partial respect. He is purposely brought into contrast with the drunken Trinculo and Stephano, with an advantageous result. He is much more intellectual than either, uses a more elevated language, not disfigured by vulgarisms, and is not liable to the low passion for plunder as they are. He is mortal, doubtless, as his "dam" (for Shakspeare will not call her mother) Sycorax. But he inherits from her such qualities of power as a witch could be supposed to bequeath. He trembles indeed before Prospero; but that is, as we are to understand, through the moral superiority of Prospero in Christian wisdom; for when he finds himself in the presence of dissolute and unprincipled men, he rises at once into the dignity of intellectual power.

Shakspeare. French and of the Italian drama, indeed we may say of the Greek, the dialogue proceeds always by independent speeches, replying indeed to each other, but never modified in its several openings by the momentary effect of its several terminal forms immediately preceding. Now, in Shakspeare, who first set an example of that most important innovation, in all his impassioned dialogues, each reply or rejoinder seems the mere rebound of the previous speech. Every form of natural interruption, breaking through the restraints of ceremony under the impulses of tempestuous passion; every form of hasty interrogative, ardent reiteration when a question has been evaded; every form of scornful repetition of the hostile words; every impatient continuation of the hostile statement; in short, all modes and formulæ by which anger, hurry, fretfulness, scorn, impatience, or excitement under any movement whatever, can disturb or modify or dislocate the formal bookish style of commencement,—these are as rife in Shakespeare's dialogue as in life itself; and how much vivacity, how profound a verisimilitude, they add to the scenic effect as an imitation of human passion and real life, we need not say. A volume might be written illustrating the vast varieties of Shakspeare's art and power in this one field of improvement; another volume might be dedicated to the exposure of the lifeless and unnatural result from the opposite practice in the foreign stages of France and Italy. And we may truly say, that were Shakspeare distinguished from them by this single feature of nature and propriety, he would on that account alone have merited a great immortality. (T. DE Q.)

[Since this essay on Shakspeare was written, the unwearied research of literary antiquaries, and the national idolatry of our great poet, have established a few additional facts. It seems to be proved, that by the paternal as well as the maternal side, Shakspeare sprung from a race of substantial yeomen (in the female branch, shading into the class of rural gentry), who were long resident at Snitterfield, about three miles from Stratford-on-Avon. His grandfather, Richard Shakspeare, occupied lands belonging to Robert Arden of Wilmecote. Richard Shakspeare had three sons, two of whom lived and died apparently as farmers, at Snitterfield. The other son, the poet's father, settled in Stratford, carrying on business as a glover, but afterwards engaging in the cultivation of land and other occupations. His acquaintance with the Arden family, from whom his father held lands, and on whose estate he was himself born, is easily accounted for; and he succeeded in obtaining the hand of Mary Arden, the seventh daughter of his father's landlord, the rural squire of Snitterfield. This lady inherited, under her father's will, the estate of Asbies, already described, with a sum of L.6, 13s. 4d, and an interest in two tenements in Snitterfield, which, when he fell into difficulties, John Shakspeare disposed of for L.4. The pedigree of the poet thus connects him, as Mr Halliwell remarks, with "the inhabitants of the valley and woodland;" and he carried in his blood the impress of the healthiest and most virtuous class in England. It need form no deduction from this estimate, that the poet's parents could not sign their names. Existing documents bear the marks of both John and Mary Shakspeare, and most of the rural middle class at this time were equally illiterate.

With respect to Shakspeare's marriage-bond, which has been considered to indicate haste and secrecy unfavourable to the reputation of Anne Hathaway, it appears that betrothment or contract of marriage generally preceded actual marriage; and was held to be as sacred and binding. The bond is of the usual tenor common at the time; and the Stratford register shows many cases in which the first child was baptized a few months after the entry of the parents' marriage, without subjecting the parties to the stigma of illegitimacy which, when it occurred, was always carefully noted in the register. The two bondsmen, Sandells and Richardson, were respectable yeomen of Shottery; and as one of the seals bears the initials "R. H.," the bride's father, Richard Hathaway, was most likely present at the ceremony. The Hathaways and John Shakspeare were early acquainted.

Malone conceived that he had completely demolished the tradition of Shakspeare's deer-stealing exploit, by showing that Sir Thomas Lucy had no park at Charlecote, but the *Egerton Papers*, published in 1840, show that Sir Thomas had deer if he had no park; for in 1602 he contributed a buck towards the entertainment of Queen Elizabeth at Harefield, and he is not likely to have purchased a buck for this purpose. The royal visit to Harefield, too, establishes another Shakspearian fact. On this occasion, a sum of L.64, 18s. 10d. was distributed among the "vaulters, players, and dancers," whom Lord Chancellor Egerton had engaged to perform before the Queen, and of this *honorarium* ten pounds were given "to Burbage's players for *Othello*." This fixes the date of *Othello* two years before the earliest date previously assigned to its production. Let us note, that in this classic mansion of Harefield, the "Arcades" of Milton, part of a masque, was subsequently performed, being written for representation by the children of the Earl of Bridgewater. Malone was happy in his conjecture that Shakspeare had purchased his Stratford house, New Place, in 1597. Mr Halliwell ascertained (1848) from the record of the fine levied on the sale, preserved in the Chapter House, Westminster, that the purchase was made at the Easter term 1597, the sum given for the messuage, barns, and garden being L.60—about L.300 of our present money. In 1602, the poet bought another property from the same individual for L.60, besides purchasing in the same year the lands of Old Stratford, for which he paid L.320; and in 1605, he made his largest purchase, giving L.440 for the unexpired term of a lease of certain tithes. These repeated investments attest not only Shakspeare's growing wealth, but his attachment to his native district—a district now, for his sake, classic and hallowed ground.

The question whether Shakspeare was a Roman Catholic has been raised. We hold that no Roman Catholic could have written parts of *King John*, *Henry VIII.*, and other dramas of Shakspeare. The old faith, however, probably held sway in the sequestered hamlet of Snitterfield. In 1844, a document was discovered in the State Paper Office, by which it appears that the poet's father, in 1592, was returned as one of the recusants who "had been heretofore presented for not coming monthly to the church, according to her Majesty's laws." The officer who makes the return reports, that John Shakspeare, and eight other men in Stratford (two of them bearing the well-known names of Fluellen and Bardolph), abstained from coming to church for "fear of process of debt." This plea is scarcely available, as John Shakspeare is found at the sametime going about on ordinary business, and four years afterwards he applied at the Herald's Office for a coat of arms, at the instigation, no doubt, of his son the poet. Whether a process for debt could then be served on Sunday is not mentioned, but we would rather attribute John Shakspeare's continued absence from church to some lingering attachment to the Papal faith, which must have been the religion of his youth. As alderman of Stratford, however, he would, in his busy days, have taken the oath then required from all functionaries. The poet's family were undoubtedly Protestants. They ultimately manifested a Puritanical devotion or seriousness; and Mr Halliwell found in the town-chamberlain's accounts for 1614, this item: "For one quart of sack and one quart of claret wine,

 given to a preacher at New Place, xxd." This was two years before Shakspeare's death. The poet had accommodated the preacher with lodgings, and the corporation, as a peculiar mark of respect, added to his "creature comforts." Perhaps the Puritanical tendencies of Shakspeare's widow and daughters may partly account for the total loss of his papers. Not a scrap has survived, not a fragment of a scene, not one familiar letter.

In commenting on Shakspeare's married life, Malone and others have charged the poet with neglect of his wife in only mentioning her in his will by an after-thought—an interlineation—and then merely giving her his second best bed. Mr Charles Knight has successfully vindicated the memory of the poet from this accusation. His property was nearly all freehold, and the widow, by the ordinary operation of the law, would be entitled to her dower, or a third of the whole. This was no doubt understood between them, and the bequest of the bed was a special and affectionate memento.

Shakspeare's sonnets seem to demand a brief notice. They were published in 1609, printed for T. T., or Thomas Thorpe, a bookseller, who dedicated them to a "Mr W. H.," styling this unknown person "the only begetter of these ensuing sonnets." So early as 1598, a contemporary writer, Meres, had mentioned Shakspeare's "sugared sonnets among his private friends," and Thorpe's collection seems to have been unauthorised and inedited. Some of the sonnets were written apparently in extreme youth, some in a feigned or assumed character, and others in the poet's advanced years. Premature age had fallen upon him in the midst of his busy and thoughtful career. Most of the sonnets are addressed to a male friend of high rank, urging him to marry; and this object of Shakspeare's extravagant admiration and worship is supposed to have been William Herbert, Earl of Pembroke, while others name the poet's patron Henry, Earl of Southampton. Little reliance can be placed on these surmises and speculations. Whatever biographical truth the sonnets possess is of a somewhat painful character, but they abound in vivid imagery and in Shakspearian thought and expression.

We subjoin Mr Knight's chronological table of Shakspeare's plays, showing the positive facts that determine the dates, apart from the internal evidence on which there will always be a diversity of opinion:—

Henry VI. Part I. Alluded to by Nash in *Pierce Penniless*	1592
Henry VI. Part II. Printed as the "First Part of the Contention"	1594
Henry VI. Part III. Printed as the "True Tragedy of Richard, Duke of York"	1595
Richard II. Printed	1597
Richard III. Printed	1597
Romeo and Juliet. Printed	1597
Love's Labour's Lost. Printed	1598
Henry IV. Part I. Printed	1598
Henry IV. Part II. Printed	1600
Henry V. Printed	1600
Merchant of Venice. Printed 1600, mentioned by Meres	1598
Midsummer Night's Dream. Printed 1600, mentioned by Meres	1598
Much Ado about Nothing. Printed	1600
As You Like It. Entered at Stationers' Hall	1600
All's Well that Ends Well. Held to be mentioned by Meres as "Love's Labour's Won."	1598
Two Gentlemen of Verona. Mentioned by Meres	1598
Comedy of Errors. Mentioned by Meres	1598
King John. Mentioned by Meres	1598
Titus Andronicus. Printed	1600
Twelfth Night. Acted in the Middle Temple Hall	1602
Othello. Acted at Harefield	1602
Merry Wives of Windsor. Printed	1602
Hamlet. Printed	1603
Measure for Measure. Acted at Whitehall	1604
Lear. Printed 1608, acted at Whitehall	1607
Taming of the Shrew. Supposed to have been acted at Henslow's Theatre 1593, entered at Stationers' Hall	1607
Troilus and Cressida. Printed 1609, previously acted at Court	1609
Pericles. Printed	1609
The Tempest. Acted at Whitehall	1611
The Winter's Tale. Acted at Whitehall	1611
Henry VIII. Acted as a new play when the Globe Theatre was burned	1613

Out of the thirty-seven plays of Shakspeare, the dates of thirty-one are thus to some extent fixed in epochs. These dates are, of course, to be modified by other circumstances. There are only six plays remaining whose dates are not thus limited by publication, by the notice of contemporaries, or by the record of their performances; and these certainly belong to the poet's later period. They are—

Macbeth.	*Timon of Athens.*	*Antony and Cleopatra.*
Cymbeline.	*Julius Cæsar.*	*Coriolanus.*

The first edition of Shakspeare's dramatic works was published by his fellow comedians, Heminge and Condell, in 1623. Of this a second edition was printed in 1632, a third in 1664, and a fourth in 1685. The first annotated or critical edition of Shakspeare was that of Rowe in 1709, and to this succeeded, before the end of the century, the more elaborate or elegant editions of Pope, Theobald, Sir Thomas Hanmer, Warburton, Johnson, Capell, Steevens, and Malone. The two last were constantly adding to their store of illustrative notes, while Chalmers, Reed, and others joined in overlaying the poet's text with a mass of verbal disquisitions and quotations which, in 1821, swelled out into an edition of twenty-one volumes. This included the notes of Malone, Boswell, and others. During the last thirty or forty years, an amount of learning, of research, and of æsthetic criticism has been brought to bear upon the genius and times of Shakspeare that baffles all computation. The proudest names in our literature have made offerings at this shrine. The scholars and critics of Germany have run a race of generous competition with those of England, and among the earliest in the two countries we may place Schlegel and Coleridge side by side. In our own day, as annotators and editors, in the new and reverent spirit, the best are Mr Dyce, Mr John Payne Collier, and Mr Charles Knight.]

SHAMAKA, or SCHEMACHA, the capital of a government of Asiatic Russia, Transcaucasia, on the Pir Saghat, 69 miles W.N.W. of Baku, and 207 E.S.E. of Tiflis. It was at one time a very flourishing and important place, being the chief seat of commerce between Persia and the north; but having been taken and sacked by Nadir Shah in 1734, it lay for a long time in ruins. Recently it has recovered a great deal of its ancient prosperity, since it was made the capital of the province of Shirvan in 1841; and since 1847, when that province was divided into the governments of Shamaka and Derbent, it has been the capital of the former. It is fortified; and contains a bazaar, with 500 stalls. Here are the most important manufactories of silk in Transcaucasia, producing goods esteemed equal to those of French manufacture. Cotton and woollen cloth is also woven here; and vines and pomegranates are grown in the vicinity. The wine of this district is considered the best in Shirvan; it is chiefly made by the Armenians who inhabit the adjacent villages. The trade of the place is very extensive. Pop. 20,433. The town is called properly Old Shamaka, to distinguish it from Aksu, or New Shamaka, on the Aksu, 20 miles S.W. Here is a castle, once the residence of the khan of Shirvan. The town has a population of 7000; and is also a flourishing place.

SHANGHAE, or SHANGHAI, a city and river-port of China, in the province of Kiang-su, on the left bank of the Woosung, which conveys the water of Lake Tahoo into the estuary of the Yang-tse-keang, 40 miles by water from the sea, and 169 E.S.E. of Nankin. N. Lat. 31. 12.; E. Long. 120. 53. It stands in a rich and well-cultivated plain, planted with wheat, rice, and cotton; and is surrounded by walls about 5 miles in circuit; but there are several extensive suburbs without the walls. Shanghae is the most northerly; and, next to Canton, the most important of the five ports that were opened to foreign trade by the treaty of 1843. Since that time the importance of the place has been very much increased, and its aspect entirely changed, by the introduction of European commerce; and a new and flourishing settlement has risen alongside of the Chinese city. What formerly was an unhealthy swamp, dotted with the wretched huts of the Chinese, is now covered with the handsome mansions of European and American merchants, and gardens, which vie with those of the Chinese, for which Shanghae has long been famous. The river, which is here half-a-mile broad and from six to eight fathoms deep, is lined with commodious quays and warehouses. Numerous large steamers and sailing-vessels are continually anchored in the river; and further up a forest of masts rises from the native craft from all parts of China, while outside the harbour many opium clippers are generally moored. The Chinese part of the city has a very different appearance from that occupied by foreigners. The streets are narrow, and not over clean, paved in general with small tiles, instead of the granite common in other Chinese towns. In the outer portions of the town business is actively carried on, and shops abound; but towards the interior these disappear, and a great deal of ground is occupied by gardens. The shops are generally small, but well stocked with all sorts of Chinese and foreign goods, especially silk, cotton, clothes, &c. Most of the houses are ill-built; and the public buildings are no way remarkable, consisting of many temples or joss-houses, several hospitals, government offices, and a mint. The tea-gardens of Shanghae, occupying a large square, planted with trees, and the large ice-houses, are worthy of observation. Some manufactures are carried on; the chief articles produced being flowered silk, paper, ivory-ware, and glass. It is for its commerce, however, both with other parts of China and with foreign countries, that the city is chiefly important. For both of these purposes its situation is very well adapted. Along the coast of China, from the Bay of Ning-po northwards, to the peninsula of Shantung, a region extending over 5 degrees of latitude, there is no port but this accessible even to moderately-sized vessels, on account of the vast amount of deposit which is brought down by the great rivers Yang-tse-keang and Hoang-ho. At the same time, the land, enriched by these gigantic streams, is the most populous and best cultivated part of China, the province of Kiang-su producing great quantities of silk. Shanghae also stands in connection with many of the distant and inland provinces, by means of the Imperial Canal, which crosses the Woosung above the town, and by the great rivers. Recently, however, the rebellion in the valley of the Yang-tse-keang, the occupation of Ching-kiang-fu, on the canal, and a change in the course of the Hoang-ho, have interrupted these means of communication; but their place has been supplied by a coasting trade between the northern and the southern ports of China. This interruption of communication has materially reduced the quantity of tea exported from Shanghae; but it has not affected the trade in silk, which has greatly increased since 1855. These two are the only goods exported in any great quantities. On the whole, the trade has considerably increased since the opening of the port. The value of the imports and exports in 1858 is exhibited in the following table:—

	Imported.	Exported.
Goods and merchandise	L.5,894,000	L.9,555,400
Specie and bullion	1,226,000	3,007,600
Known total	L.7,115,600	L.12,563,000
Opium	4,944,400	
Grand total	L.12,061,000	

As the opium is a prohibited article, and presumed to be unknown to the Chinese officials, its value can only be estimated. The above estimate includes 25,122 chests of Malwa opium, valued at L.3,617,568, and 7238 chests of Patna opium, valued at L.1,129,128. Among the imports are also included 414,505 pieces of American gray twills, and 36,400 pieces of American sheetings. The quantities of silk and tea exported in the same year were as follows:—

Silk.

Countries.	Raw.	Thrown.	Total.
Great Britain ......bales	24,957	1494	26,451
Hong-Kong	37,804	4971	42,775
Foo-Chow	209	8	217
United States	1,614	19	1,633
Manilla	201	2	203
Total	64,785	6494	71,279

Besides this, there were exported 391 bales of coarse silk, 138 of refuse, and 921 of cocoons, all to Great Britain.

Tea.

Countries.	Black.	Green.	Total.

Total	754	242,624	378	154,795

Shanghae was taken by the British in June 1842, but restored to the Chinese by the treaty ratified in the following year. In September 1853 it was captured by the insurgent forces, but regained by the Imperialists soon afterwards. The population is variously estimated; it is probably between 115,000 and 135,000, though some accounts make it as much as 300,000.

SHANNON, a river of Ireland, by far the largest in that country, and one of the most important in the United Kingdom. Its source is at the foot of Caileagh, one of the mountains in the county of Cavan, which surround Lough Allen, into which it falls after a course of a few miles. Out of this lake, which is about 10 miles in length, it issues at its southern extremity, and flows in an irregular course, generally southwards, in a narrow, shallow, and somewhat interrupted bed. It receives the Boyle River from Lough Key on the right, and further down it expands into a sheet of water called Lough Bodarrig. Beyond this it flows through a wide expanse of boggy land, till it enters the northern extremity of Lough Ree at Lanesborough. This lake is the second in size of those the Shannon flows through,

being 17 miles in length by 7 in its greatest breadth. It is diversified by many promontories, bays, and creeks, and has very beautiful scenery. Issuing from Lough Ree, a little above Athlone, the Shannon continues to pursue a circuitous and southerly course, through a low, flat, and fertile region, dividing itself at some places into arms which enclose considerable islands. In this part of its course, the Suck, its chief affluent, and little inferior to the main river, joins the Shannon from the west, after a course of 60 miles. The largest lake that the river flows through is Lough Derg; it is 25 miles long, narrow, and much indented. It is also the most beautiful in its scenery; for, unlike the others which lie in low ground, a great portion of this lake, especially its lower end, is environed by mountains; Slievh Boughty rising on the west, and the Arra Mountains on the east. From Killaloe at the foot of Lough Derg, the Shannon flows south-west to Limerick; and about half-way between these places are the falls of Doonass. These are, properly speaking, rapids; the river, which is here 40 feet deep and 300 yards broad, rolling tumultuously over a succession of rugged rocks for about half a mile, in the midst of luxuriant meadows and shaggy woods; while the ruins of Castle Connel occupy a lofty rock overlooking the stream. From Limerick onwards the course of the Shannon is due west, and it is here rather an estuary or arm of the sea than a river, though it is known by the name of the Lower Shannon. It enters the Atlantic between Look Head on the north, and Kerry Head on the south. Several rivers join it in this part of its course, the chief of which is the Fergus, from the north. The whole length of the Shannon, from its source to the sea, is 220 miles. During its course from Lough Allen to below Lough Bodarrig it separates the counties of Leitrim and Roscommon; from thence to the lower part of Lough Derg it divides Leinster and Munster on the one side, from Connaught on the other; Longford, Westmeath, and King's County belonging to the first, Tipperary to the second, Roscommon and Galway to the third of these provinces. The rest of its course lies in Munster, between Clare on the north, Limerick and Kerry on the south. The most remarkable thing about the Shannon is the length of navigable water it has. In this respect it is far superior to any river in the United Kingdom, for vessels may ascend from its mouth as far as Lough Allen, so that there are only 6 or 7 miles out of 220 that cannot be navigated. There are, indeed, at various places obstructions caused by the shoals and rapids of the river; but these have, for the most part, been overcome by lateral canals, or by deepening the channel. Upwards of half a million sterling has been expended on various works for the improvement of the river; and yet, from the want of proper management, it is still in an unsatisfactory state. The value of such a river to the country is necessarily very great, as it connects the most inland places with the sea, and by the Grand and Royal Canals to Dublin inland navigation is extended also to other parts of the island. The highest tides in the Shannon rise about 18 feet, the lowest 14; the velocity in narrow parts of the estuary is frequently very great, and the water assumes an appearance very like that of a bore. Several varieties of fish are found in the Shannon, and the most productive fishery is that of eels.

SHAN-SI, or Shan-see, an inland province of China, bounded on the N. by Mongolia, from which it is separated by the Great Wall, E. by Pe-che-li, S. by Honan, and W. by Shen-si. Area, 55,360 square miles. The surface is in general mountainous, but there are many level tracts. The largest river is the Hoang-ho, which forms the whole of the western and part of the southern boundary. It receives many affluents, which, though small compared with the giant streams of China, would anywhere else be considered of great size. The Tan-ho, the largest of these in this province, has a length of 300 miles. In the north of Shan-si are some of the favourite hunting-grounds of the Chinese emperors. The productions of the province are rice, wheat, millet, coal, iron, lapis lazuli, salt, jaspers, musk, rice, brandy, carpets, &c. The chief town is Tai-yuen-fu. Pop. (1812) 14,004,210, (1843) 15,000,000.

SHAN-TUNG, a maritime province of China, bounded on the N. by the gulf of Pe-che-li, E. and S.E. by the Yellow Sea, S. by Kiang-su and Honan, W. and N.W. by Pe-che-li. Area, 65,216 square miles. The eastern portion forms a peninsula projecting into the sea, and separating the gulf of Pe-che-li from the Yellow Sea. This part is mountainous, but the rest of the province consists of a plain traversed by the Imperial Canal. It is intersected by several rivers, but none of any great size fall into the sea, if we except the Hoang-ho, which only forms the boundary for a short distance. The coast is bold, and has many harbours, but no large seaport towns. The chief productions are wheat, millet, indigo, coarse silk, and carpets. Pop. (1812) 28,958,764, (1843) 30,000,000.

SHAPINSHAY. See Orkney.

SHARP, Abraham, an eminent English mathematician and astronomer, was born at Little Horton, near Bradford, in the year 1651. He was put as apprentice to a merchant at Manchester, but so strongly was he inclined to the study of mathematics that he soon found his situation both irksome and disagreeable. By the mutual consent, therefore, of his master and himself, he quitted the business of a merchant. He then removed to Liverpool, where he devoted himself wholly to mathematical studies, and where, for a subsistence, he taught writing and accounts. Soon after this, a merchant from London, in whose house the celebrated Flamsteed then lodged, engaged Sharp to be his bookkeeper. With this eminent astronomer he soon contracted an intimate friendship, and by his recommendation he obtained a more profitable employment in the dock-yard of Chatham, where he continued till his friend and patron called him to his assistance. Sharp was chiefly employed in the construction of the mural arch, which he finished in the couse of fourteen months, so entirely to the satisfaction of Flamsteed, that he spoke of him in terms of the highest praise. In the opinion of Smeaton, this was the first good instrument of the kind, and Sharp the first artist who cut delicate divisions on astronomical instruments. When this instrument was constructed, Sharp was but twenty-five and Flamsteed thirty years of age. Sharp assisted his friend in making a catalogue of nearly three thousand fixed stars, with their longitudes and magnitudes, their right ascensions and polar distances, with the variations of the same while they change their longitude by one degree. But, from the fatigue of constantly observing the stars by night in a cold thin air, added to a weakly constitution, his health was much impaired. For the recovery of it he requested leave to retire to his house at Horton, where, as soon as he felt himself recovering, he began to fit up an observatory of his own; and the telescopes he made use of were all of his own construction, and the lenses ground and adjusted with his own hands.

It was about this time that he assisted Flamsteed in calculating most of the tables in the second volume of his *Historia Cœlestis*, as appears by their letters, to be seen in the hands of Sharp's friends at Horton. Sharp, in 1717, published an elaborate treatise on Geometry, which he entitled *Geometry Improved*. He possessed a remarkably clear head for contriving, and an extraordinary hand for executing anything, not only in mechanics, but likewise in drawing, writing, and making the most beautiful figures, in all his calculations and constructions. The quadrature of the circle was undertaken by him for his own amusement, in the year 1699, deduced from two different series, by which the truth of it was proved to seventy-two places of figures, as may be seen in Sherwin's *Tables of Logarithms*.

In the same book may likewise be seen his ingenious improvements on the making of logarithms, and the constructing of the natural sines, tangents, and secants.

Sharp kept up a correspondence with most of the eminent mathematicians and astronomers of his time, as Flamsteed, Newton, Halley, Wallis, Hodgson, the answers to whose letters are all written on the backs or empty spaces of the letters he received, in a short hand of his own invention. Being one of the most accurate and indefatigable computers who ever existed, he was many years the common resource for Flamsteed, Sir Jonas Moor, Halley, and others, in all sorts of troublesome and delicate calculations. Sharp was never married, and spent his time as a hermit. He was of a middle stature, very thin, of a weakly constitution, and remarkably feeble during the last three or four years before his death, which happened on the 18th of July 1742, in the ninety-first year of his age. He was very irregular as to his meals, and uncommonly sparing in his diet. A little square hole, resembling a window, formed a communication between the room where he usually studied, and another where a servant could enter; and before this hole he had contrived a sliding board. It often happened, that the breakfast, dinner, and supper remained untouched; and when the servant returned to remove the dishes, the meal was found just as it had been left.

SHARP, Granville. See Slavery.

Sharp, *James*, Archbishop of St Andrews, was born of a good family in Banffshire in the year 1618. He devoted himself early to the church, and was educated for that purpose in the University of Aberdeen. When the solemn league and covenant was framed in 1638, the learned men in that seminary, and young Sharp in particular, declared themselves decidedly against it. To avoid the insults and indignities to which he was subjected in consequence of this conduct, he retired to England, where he contracted an acquaintance with some of the most celebrated divines in that country. At the commencement of the civil wars he returned to Scotland. During his journey thither, he accidentally met with Lord Oxenford, who was so charmed with his conversation that he invited him to his house. While he resided with that nobleman, he became known to the Earl of Rothes, who procured him a professorship at St Andrews. By the interest of the Earl of Crawford, he was soon afterwards appointed minister of Crail, where he conducted himself, it is said, in an exemplary manner. Sharp had always inclined to the cause of royalty, and had for some time kept up a correspondence with his exiled prince. After this he began to declare himself more openly, and seems to have enjoyed a great share of the confidence of Monk, who was at that time planning the restoration of Charles II. When that general marched to London, the presbyterians sent Sharp to attend him, in order to support their interests. At the request of General Monk and the chief presbyterians in Scotland, Mr Sharp was sent over to the king at Breda, to procure from him, if possible, the establishment of presbytery. On his return, he assured his friends that "he had found the king very affectionate to Scotland, and resolved not to wrong the settled government of the church; but he apprehended they were mistaken who went about to establish the presbyterian government."

Charles was soon afterwards restored without any terms. All the laws passed in Scotland since the year 1633 were repealed; the king and his ministers resolved at all hazards to restore prelacy. Sharp, who had been commissioned by the Scotch presbyterians to manage their interests with the king, was prevailed upon to abandon the party; and as a reward for his compliance, he was made archbishop of St Andrews. This conduct rendered him very odious in Scotland. He was accused of treachery and perfidy, and reproached by his old friends as a traitor and renegade. The absurd and wanton cruelties which were afterwards committed, and which were imputed in a great measure to the archbishop, rendered him still more detested. Nor is it probable that these accusations were without foundation. The very circumstance of his having formerly been of the presbyterian party would induce him, after forsaking them, to treat them with severity. Besides, it is certain, that when, after the rout at Pentland Hills, he received an order from the king to stop the executions, he kept it for some time before he produced it to the council.

There was one Mitchell, a preacher, and a desperate fanatic, who had formed the design of taking vengeance for these cruelties by assassinating the archbishop. He fired a pistol at him as he was sitting in his coach; but the bishop of Orkney, lifting up his hand at the moment, intercepted the ball. Though this happened in the midst of Edinburgh, the primate was so much detested, that nobody stopped the assassin, who, having walked leisurely home, and thrown off his disguise, returned, and mixed unsuspected with the crowd. Some years afterwards, the archbishop observing a man eyeing him with keenness, suspected that he was the assassin, and ordered him to be brought before him. It was Mitchell. Two loaded pistols were found in his pocket. The primate offered him a pardon if he would confess the crime. The man complied; but Sharp, regardless of his promise, conducted him to the council. The council also gave him a solemn promise of pardon, if he would confess his guilt, and discover his accomplices. They were much disappointed to hear that only one man was privy to his purpose, who was since dead. Mitchell was then brought before a court of justice, and ordered to make a third confession, which he refused. He was imprisoned for several years, and then tried. His own confession was urged against him. It was in vain for him to plead the illegality of that evidence, and to appeal to the promise of pardon previously given. The council took an oath that they had given no such promise, and Mitchell was condemned. Lauderdale, who at that time governed Scotland, would have pardoned him, but the primate insisted on his execution, observing, that if assassins were permitted to go unpunished, his life must be continually in danger. Mitchell was accordingly executed.

Sharp had a servant, one Carmichael, who by his cruelty had rendered himself particularly odious to the zealots. Nine men formed the resolution of waylaying him in Magus Moor, about three miles from St Andrews. While they were waiting for this man, the primate himself appeared, with very few attendants. This they looked upon as a declaration of Heaven in their favour; and calling out, "The Lord has delivered him into our hands," they ran up to the carriage. They fired at him without effect, a circumstance which was afterwards imputed to magic. They then despatched him with their swords, regardless of the tears and entreaties of his daughter, who accompanied him. On the 3d of May 1679, thus fell Archbishop Sharp, whose memory is even at present detested by the common people of Scotland. His abilities were certainly good, and in the early part of his life he appears with honour and dignity. But his conduct afterwards was too cruel and insincere to merit approbation. His treatment of Mitchell was mean and vindictive. How far he contributed to the measures adopted against the Presbyterians is not certain. They were equally cruel and impolitic; nor did their effects cease with the measures themselves. The unheard-of cruelties exercised by the ministers of Charles II. against the adherents of the Covenant raised such a flame of enthusiasm and bigotry as is not yet entirely extinguished.

Sharp, *John*, Archbishop of York, was descended from the Sharps of little Norton, a family of Bradford Dale in Yorkshire; and was son of an eminent tradesman of Bradford, where he was born in 1644. He was educated at Cambridge, and in 1667 entered into orders. The same

year he became domestic chaplain to Sir Heneage Finch, then attorney-general. In 1672 he was collated to the archdeaconry of Berkshire. In 1675 he was installed a prebendary in the cathedral church of Norwich; and the year following was instituted into the rectory of St Bartholomew, near the Royal Exchange, London. In 1681 he was, by the interest of his patron, Sir Heneage Finch, then lord high chancellor of England, made dean of Norwich, but in 1686 was suspended for taking occasion, in some of his sermons, to vindicate the doctrine of the Church of England in opposition to Popery. In 1688 he was sworn chaplain to James II., being then probably restored after his suspension; for it is certain that he was chaplain to Charles II., and attended as a court chaplain at the coronation of James II. In 1689 he was declared dean of Canterbury, but never could be persuaded to fill up any of the vacancies made by the deprived bishops. Upon the death of Dr Lamplugh, he was promoted to the see of York. In 1702 he preached the sermon at the coronation of Queen Anne; and the same year he was sworn of the privy council, and made Lord Almoner to her Majesty. He died at Bath in 1713, and was interred in the cathedral of York, where a monument was erected to his memory. His sermons were collected after his death and published in seven vols. 8vo. A *Life of Archbishop Sharp*, written by his son, Dr Thomas Sharp, appeared in 2 vols. in 1829.

Sharp, *William*, an eminent line-engraver, was born at London on the 29th of January 1749. He was originally apprenticed to what is called a bright engraver, but gradually becoming inspired by the higher branches of the engraver's art, he exercised his gifts with surprising success on works of the old masters. He engraved the "Doctors Disputing on the Immaculateness of the Virgin," and the "Ecce Homo" of Guido Reni; the "St Cecilia" of Domenichino; the "Virgin and Child" of Dolci; and the portrait of "John Hunter" of Sir Joshua Reynolds. The latter work is considered a masterpiece in freedom and accuracy; and, in a power which Sharp possessed beyond all engravers of his day, of representing the various textures of his subject with wonderful skill. He died at Chiswick on the 25th July 1824. Sharp, although shrewd-minded in worldly matters, was one of the greatest visionaries in matters pertaining to religion. No imposture was too gross for him to accept, no deception too glaring for his eyes to admire. The dreams of Mesmer, the rhapsodies of Brothers, and the ravings of Joanna Southcott, found in Sharp a staunch believer. At his death he enjoyed the honour of being a member of the Imperial Academy of Vienna, and of the Royal Academy of Munich.

SHARPE, Daniel, an English geologist, was born in London in 1806. His mother, who died shortly after his birth, was a sister of the poet Rogers. He was educated at Walthamstow, and showed early a predilection for the study of natural science. He became a member of the Geological Society in June 1829, and read a short memoir the following year on a fine specimen of Ichthyosaurus, from the lias of Stratford-on-Avon. It turned out that this species of reptile had previously been noticed by Conybeare. During the next twenty years Sharpe's attention was much directed to the geology of Lisbon and Oporto, and during these years he read numerous papers before the Geological Society. He had been led thither by his profession of a wine-merchant, and it was to his labours that the society owes the greater part of its knowledge of the geological structure of the district of the Tagus. He examined the relations of the earthquake of 1755 to the geological structure of the site of Lisbon, and found that while all the buildings occupying the tertiary strata had been demolished, those situated on the hippurite limestone and basalt had entirely escaped. In 1848 he gave a detailed account of the coal deposits of Vallongo, in Portugal, and inclined to the opinion that this substance was really of the Silurian age. Next year he combined a general sketch of the geology of Portugal, with a notice of the structure of the district north of the Tagus; and as this necessitated great labour, he gained the assistance of various scientific friends. He was enabled, by his critical examination of organic remains, to present a lucid paper on the comparison of the North American formations with those of Europe in 1847. He reviewed the classifications of Belgium and England in 1852, of South Westmoreland in 1842 and 1843, of the Bala Limestone in 1842, and of North Wales in 1846. Sharpe likewise collected many papers, and devoted much thought and labour to the subject of slaty cleavage, on which he read his first memoir in 1846. He engaged in an investigation of the geology of the Highlands of Scotland with Greenough, with the design of constructing a new geological map of Scotland for the Geological Society of London. The account of his labours on this district will be found in the *Philosophical Transactions* for 1852. He likewise wrote a paper on the Farringdon gravels in 1853, which bespeaks his palæontological industry. His elaborate essays on the ancient coins and inscriptions of Lycia, appended to the works of Fellows, Forbes, and Spratt, display in an eminent degree his knowledge of philology and ethnology. He was Fellow of the Royal, Linnean, and Zoological Societies, and occupied at the time of his death, which happened on the 31st of May 1856 (occasioned by a fall from his horse), the post of President of the Royal Geological Society, to which so much of his labour and so large a portion of his time had been devoted for more than a quarter of a century.

SHASTER. See Brahmins.

SHATZK, or Schazk, a town of European Russia, on the Shatzka, in the government of Tambov, 38 miles N. of Morshansk. It has 5 churches, several schools, a benevolent institution, manufactures of hardware, and a considerable trade. Pop. 6207.

SHAW, Dr Thomas, known to the learned world by his *Travels to Barbary and the Levant*, was born at Kendal, in Westmoreland, about the year 1692. He was appointed chaplain to the English consul at Algiers, in which station he continued for several years; and thence took proper opportunities of travelling into different parts. He returned in 1733, was elected fellow of the Royal Society, and published the account of his travels at Oxford, 1738, folio. In 1740 he was nominated principal of St Edmund Hall, which he raised from a ruinous state by his munificence; and was regius professor of Greek at Oxford until his death, which happened in 1751. Dr Clayton, bishop of Clogher, having attacked these *Travels* in his *Description of the East*, Dr Shaw published, by way of vindication, a supplement, which is incorporated into the second edition of his Travels, prepared by himself, and published in 1757, 4to.

SHAWLS. See Woollen Manufactures and Weaving.

SHEE, Sir Martin Archer, a portrait-painter, and president of the Royal Academy, was born in Dublin on the 23d of December 1770. He was sprung from an old Irish family, and his father, while he exercised the trade of a merchant, regarded the profession of a painter as in no sense a fit occupation for a descendant of the Shees. Young Shee became, nevertheless, a student of art in the Dublin Society, and came early to London, where he was, in 1788 introduced to the notice of Sir Joshua Reynolds by the youth's illustrious friend and countryman Edmund Burke. Having entered as a student in the Royal Academy in 1789, he contributed the same year his first two pictures to the exhibition, the "Head of an Old Man" and "Portrait of a Gentleman." During the next ten years he steadily increased in practice, and was gradually gaining ground among the aristocracy, with whom his suavity and

manners were a great recommendation. Lord Spencer was the first nobleman who honoured his studio with his portrait, and his example was soon followed by dukes and marquises in abundance. Lawrence, however, had an entire monopoly of the ladies. Shee was chosen an associate of the Royal Academy in 1798, shortly after the illustrious Flaxman, and in 1800 he was made a Royal Academician. He now removed to Romney's house in Cavendish Square, and set up as the legitimate successor of that artist. Shee continued to paint with great readiness of hand and fertility of invention, although his portraits were eclipsed by more than one of his contemporaries, and especially by Lawrence, Hoppner, Phillips, Jackson, and Raeburn. He had a fine eye for colour, but one of his most glaring defects was a deficiency in proportion. In 1805 he came out with a poem consisting of *Rhymes on Art*, and it was succeeded by a second part in 1809. Although Byron spoke well of it in his *English Bards and Scotch Reviewers*, and invoked a place for "Shee and Genius" in the temple of fame, yet as nature had not originally conjoined these two, it is to be feared that even a poet's invocation could not materially affect their relations. Shee published another small volume of verses in 1814, entitled *The Commemoration of Sir Joshua Reynolds and other Poems*, but this effort did not greatly increase his fame. He now modified his theatrical experience by writing a tragedy called *Alasco*, of which the scene was laid in Poland. The play was accepted at Covent Garden, and in the fertile fancy of the poet the play had already gained for him a great dramatic fame, when Colman, the licenser, refused it his sanction, on the plea of its containing certain treasonable allusions, and Shee, in great wrath, resolved to make his appeal to the public. This violent threat he carried out in 1824; but unfortunately the public found other business to mind, and *Alasco* is still on the list of unacted dramas.

On the death of Lawrence in 1830, Shee was chosen President of the Royal Academy, more from a regard to his elegant addresses than for any artistic genius with which he was held to be endowed. Wilkie was a candidate, but he had little else than genius in his profession to recommend him, and of course Shee's fluency of speech and courtly address were of much more consequence in the academic chair than the reserved manner and undecided utterance of a much greater man. Shortly after Shee received the honour of knighthood. He continued to paint till 1845, and died five years afterwards, on the 13th of August 1850, in his eightieth year.

SHEERNESS, a seaport and market-town of England, in the county of Kent, on the north-west corner of the Island of Sheppey, at the confluence of the Medway with the Thames, 20 miles N.N.E. of Maidstone, and 47 E. by S. of London. It consists of three parts, Sheerness proper, Bluetown, and Miletown; the first contains the dockyards and fortresses, and this, as well as the second, is encircled by fortifications, beyond which lies the suburb called Miletown. The town has been much improved, especially within recent years, and now contains several handsome streets, with good brick houses. The dockyard and buildings connected with it occupy an area of 60 acres, enclosed by a brick wall. Here there are all the establishments necessary for the building, repairing, and equipment of ships. There is a basin or wet-dock 520 feet by 300, covering an area of 3½ acres; two others of smaller size; three dry docks, each 248 feet by 88; sheers for lifting masts, 127 feet high; a building slip; store-houses, joiners' and smiths' shops; residences for the commander-in-chief, and various other officials; besides an ordinance-office, and heavy batteries of 100 guns. The dockyard is built on piles; and since 1815 about 3,000,000 sterling have been laid out upon its improvement. Near the dock-gates stands a large and handsome chapel, attached to the garrison; and in the town is a Gothic district church, belonging to the parish of Minster. The other places of worship belong to the Wesleyan Methodists, the Baptists, the Roman Catholics, and the Jews. There are also various schools, a mechanics' institute, reading societies, and a savings bank. A county court is held in the town, and there are weekly markets. The trade is very considerable; but depends chiefly on the dockyards, although corn and seeds from the Isle of Sheppey, and oysters from the adjacent banks, are conveyed to London. Copperas is manufactured at a short distance from Sheerness, the materials being supplied in abundance from the multitude of pyrites found in the rocks to the east. Sheerness is resorted to as a sea-bathing place to a considerable extent. There is a pier 1000 yards long, for the steamers that ply daily between this and London. The town is of comparatively recent origin, as it is not yet 200 years since its foundation. In the time of the Commonwealth, the site was a mere swamp, on which a fort with 12 guns was built after the Restoration. But before the works could be completed, the Dutch, in 1667, entered the Thames, and took and destroyed the fort. It was afterwards restored and enlarged, the dockyard was established, which has become one of the finest in Europe, and additions were made to the works at various subsequent times. In 1797, Sheerness was threatened by the mutiny of the fleet at the Nore; but was saved by the suppression of that movement in the same year. The town suffered from an extensive conflagration in 1827, but was speedily restored in a superior style. Pop. 8549.

SHEFFIELD is an ancient manufacturing town, near the southern extremity of the West Riding of Yorkshire, and about 160 miles N.N.W. of London. The manor of Sheffield, with several of the adjacent manors, was anciently called Hallamshire, and its lord had his castle at the confluence of the rivers Sheaf and Don. The name Sheffield is commonly supposed to be derived from the Sheaf. In *Doomsday Book* the town is called Escafelt, and antiquaries derive its name from the British word *ea*, water. The Don is the principal river, and at or near the town it receives the waters of its tributaries, the Sheaf, the Porter, the Loxley, and the Rivelin. All these have their source in the high moors a few miles west, south-west, and north-west of the town. To the abundant water-power thus supplied, and to the coal and iron obtained here at a very early period, may be ascribed the devotion of Sheffield to working in iron and steel. The valleys are studded with grinding-wheels and tilts, worked by water-power. These valleys are separated from each other by bold and steep hills, and though the effect is to render the neighbourhood remarkably picturesque and beautiful, in the town the inequalities of surface have their inconveniences, for some of the streets are so steep as to be quite unsuited for loaded vehicles. A hundred years ago Sheffield was described as a smoky town, but now the reasons for that reproach are increased ten thousand times. A bye-law of the corporation requires the consumption of smoke from steam-engines, and the manufacturers have incurred great expense in endeavouring to obey the law, with only partial success. Besides the Castle of Sheffield, the Earls of Shrewsbury, who were its lords for 200 years, had a lodge or manor-house in a finely wooded park, a mile east of the town. The greater part of the captivity of Queen Mary of Scotland was passed at the castle and manor-house at Sheffield. The castle was demolished by order of parliament in 1648. Only such names as Castlehill, Castlegreen, &c., remain to mark the site. The manor-house has crumbled away under the hand of time, and only a few poor traces are left. The park was divided into farms in 1707, but the district still bears its old name. By the marriage of the heiress of the seventh Earl of Shrewsbury with a member of the house of Howard, the estates have passed to the Duke of Norfolk. The present

duke has had a mansion called "The Farm," immediately adjoining the town, enlarged and furnished for his occasional residence. During the suit brought by Lord Talbot successfully in 1858, to support his claim to the earldom of Shrewsbury, the Shrewsbury vault under the chancel of the parish church was searched for evidence, but without result. The modern history of Sheffield has been for the most part peaceful, but on the night of the 11th January 1840, the town narrowly escaped from a Chartist conspiracy to burn and capture it. The scheme was not disclosed to the authorities till almost the last hour. Sheffield has grown rapidly during the present century. The population of the borough is four times as great as it was at census of 1801, being now computed at 180,000. At the census of 1851 it was 135,307. The rateable value of the property of the borough was L.272,161 in 1848, and L.425,044 in 1859. The parochial and municipal taxes for the years ending in 1858 and 1859 were from L.96,000 to L.98,000 each year.

The town and neighbourhood of Sheffield are indisputably the chief seat of the following important manufactures:—Cast, shear, and blister steel, of all kinds; steel wire; railway and carriage springs; buffers; files; saws; all kinds of joiners', masons', shipwrights', and mechanics' edge-tools generally; scythes, sickles, hay and straw knives; table, pocket, shoe, butchers', and similar cutlery of every variety; all classes of silver, silver-plated, electro-plated, German silver, Britannia, and other white-metal goods; women's and tailors' scissors and shears; razors; silver and silver-plated cutlery; sheep-shears, skates, spades, and shovels; surgical instruments; many kinds of horticultural and agricultural tools; adzes, axes, hatchets, hammers, augers, hoes, bill-hooks, &c., in all varieties of pattern and quality. In a more limited sense, too, this town is an important seat of such manufactures as those of hair-seating and curled hair; combs of all kinds; powder-flasks and shot-belts; optical instruments; needles, fish-hooks, awls; stove-grates, and fine foundry-work of all varieties; many kinds of machinery, and railway and mining tools. The manufacture of snuff is also carried on here on an extensive scale, Messrs Wilson and Co. and J. and H. Wilson producing an article, as snuff-takers know, which has a reputation almost equal to that of the celebrated pocket-knives of the Messrs Rodgers themselves. This list of trades is very different from that given in the charter of the Cutlers' Company in 1624, which enumerated only "knives, scissors, shears, sickles, and other cutlery." The natural advantages of this neighbourhood, however, for the production of hardware are sufficiently pre-eminent to have justified the expectation of a still larger extension of local industry, and of course a proportionate increase in the town itself. There can be no doubt that the dominating power and influence of the trades' unions have tended, by making skilled labour artificially dear, and by stereotyping the occupations of men too much, first, to encourage foreign manufacturers, especially in Germany and the United States; and, second, to discourage attempts to introduce and localise any new and experimental manufactures, to the success of which cheap, abundant, and unprejudiced mechanical skill was absolutely essential. In spite of all this, however, energy and perseverance on the side of the masters, and the crushing effect of reason and experience on the side of the men, have been sufficient, in a great degree, to override the suicidal effects of trade combinations. It is a law in commerce, that if a trade be once fairly wrested from a locality, it never can be wholly, or even materially, recovered. This is the experience of Sheffield. Whatever branches of manufacture the policy of trades' unions has thrown into the hands of the Americans or the Germans, they keep; but they will not easily take any more. Meanwhile, the new employments of the town are rapidly growing into importance. It has been stated by one of the principal manufacturers of railway-springs, that the quantity of them made *weekly* in Sheffield is 150 tons. The buffer trade is increased at a corresponding rate. Twenty years ago it was estimated that about 700 tons of Swedish iron were annually brought to Sheffield, and converted into steel. Since that time experience and competition have forced English irons to a very large amount into use for the purpose of making steel, and hence the importation of Swedish and other foreign marks, though not perhaps on the decline, is almost stationary. Some of the principal railway-spring makers have recently erected puddling furnaces, and produce their own malleable iron from the pig-metal. They can thus combine the various kinds of iron best suited to their purpose. East Indian and Nova Scotian irons are coming into use among other varieties. From the statistics furnished by Messrs Sanderson and Unwin, of Sheffield, to Mr Tylor, for his report on metal work in the Paris Exhibition, we gather that, in 1856, there were in Sheffield 206 converting or blister steel furnaces, and 2113 melting boles, or cast-steel furnaces. At the rate of 250 tons each per annum, the blister steel furnaces were estimated to have produced 51,500 tons of steel, of which 37,800 tons were then made into cast-steel, and the rest sold as bar, German, faggot, spring, and shear steel. If the cast-steel be taken as worth L.40, and the rest at L.25 per ton, it will be found that, in 1856, steel to the value of L.1,854,500 was made in Sheffield. From what has been already said, it will be inferred that the trade of Sheffield is very widely spread. In truth, every country abroad, as well as the whole home-market, are directly or indirectly her customers. Next to the home trade, perhaps no other calls for a larger quantity of goods than that of the United States and British North America. Australia, South America, both east and west coast, and the Cape of Good Hope, are, however, excellent markets; and the demand for steel, files, saws, railway-springs and buffers, and tools generally, of course naturally springs up wherever railways are being constructed, or ships and machinery built. At present Russia, several other European countries, and India, are large purchasers of these classes of goods. From the fact that reliable local statistics are very difficult to procure (the nature of the trades not rendering any attention to these points necessary), it is impossible to say, with much approach to accuracy, how the population is divided as regards employment in the various trades. The rate of wages, however, usually paid in some departments of labour can be ascertained with greater truth. According to returns made at the request of Mr Fonblanque, at the head of the statistical department of the Board of Trade, the average wages, per day, paid in the following trades (taking the trades in whole and not in detail) during 1855–56–57, were:—

Table-knives...	2s. 6d. to 7s. 0d.	Steel...........	3s. 6d. to 8s. 0d.
Pocket-knives	3s. 0d. to 7s. 0d.	Springs	6s. 0d. to 8s. 0d.
Razors	2s. 6d. to 8s. 0d.	Stove-grates...	4s. 0d. to 7s. 0d.
Scissors.........	3s. 3d. to 5s. 6d.	Silver-platers..	4s. 0d. to 8s. 0d.
Files	3s. 9d. to 8s. 0d.	Britannia metal makers.......	1s. 4d. to 6s. 0d.
Saws............	4s. 0d. to 8s. 0d.		
Tools...........	5s. 0d. to 7s. 0d.		

When it is borne in mind, that as a rule the families of the working classes here occupy separate houses, and that cellars or "flats" are unknown as human habitations, it will be obvious that a very great degree of comfort is within the reach of the working-man, and that it is his own fault if, with such wages and such collateral advantages, he is not a thriving man, and his family well fed, well clothed, and decently educated.

In 1832 Sheffield was empowered to return two members to parliament; and in 1843 it was incorporated by royal charter. The parliamentary and municipal borough is co-extensive with the old parish of Sheffield, which consists of six townships. The parliamentary voters are about

Sheffield. 7000, and the names on the burgess-roll about 19,000. It is ascertained that a L.6 *rental* qualification would enfranchise about 20,000 voters; and a L.6 *rating*, 11,000. The town has a bench of borough magistrates, but no separate court of quarter sessions. Persons committed for trial are sent to the West Riding quarter sessions, or to the assizes at York. The old manorial courts, for the recovery of debts to the amount of L.5, have been superseded by the county court, with jurisdiction up to L.50, and holding frequent sittings here. The Sheffield barracks, erected in 1794, having become too small, as well as dilapidated, were pulled down in 1855, having been replaced by new barracks, occupying a site of 25½ acres. They have since been further extended. A free library, maintained by rate, was established in 1856. In 1859 it had 9119 volumes, and the issue of books for the year was 125,555. Most of the church and chapel yards having been closed as places of interment in 1855, and the Sheffield Cemetery, established in 1836, being insufficient to meet the case, several new township cemeteries have been formed. Previous to 1820 Sheffield had only its old parish church, built 1110; St Paul's and St James', built during the last century; and two small chapels of ease in out-townships. Since that time a vast increase of ecclesiastical buildings has taken place. Between 1820 and 1830 four churches were built under "the million act." During the following years, and chiefly during the last fifteen, a crowd of new churches has been built and endowed by voluntary effort. In 1846, the old parish of Sheffield was divided into twenty-five parochial districts, which are for the most part independent of the old parochial head, except that the old parish of Sheffield now forms a deanery, of which the Vicar of Sheffield is the rural dean. Most of the new districts or parishes are already supplied with churches. Of old and new churches there are now twenty-three, and others are projected or in progress. The Nonconformist bodies have nearly doubled their places of worship since 1833. They now number about forty. The Roman Catholics have replaced their small chapel, erected in 1814, by a large and handsome church, with a spire rivaling that of the ancient parish church. In 1856 they erected a smaller church in another part of the town. Both these churches have schools. A school has also been erected near the residence of the Duke of Norfolk, and a convent and school of the Sisters of Notre Dame has been established. All the religious denominations have their Sunday schools, and in connection with many places of worship are efficient day-schools. It is to be regretted that the people do not fully avail themselves of the many facilities for education offered to them.

Among the educational establishments of the town are the People's College, a self-supporting institution, conducting efficient day and evening classes; the Church of England Educational Institute, managed by several of the clergy and influential laymen with great success; and the Mechanics' Institution, which here languishes. The Government School of Art at Sheffield is one of the best conducted of these institutions in the provinces. The Wesley College and the Collegiate School (Church of England), with the old endowed Grammar School, are the principal institutions, excepting private schools, for the education of the middle classes.

The Cutlers' Company, known throughout the kingdom by its anniversary, called the "Cutlers' Feast," had its origin in the sixteenth century in certain trade regulations, wholly opposed to modern ideas, "agreed upon by the whole fellowshippe of cutlers," sanctioned by the then Earl of Shrewsbury, and enrolled among the records of his manor court. The company was incorporated by statute in the 21st James I., but its restrictive powers, having been mitigated in 1801, were swept away in 1814. It has since had little further power than to grant marks to the manufacturers of "knives, sickles, shears, scissors, and other cutlery wares." Application will be made to parliament in 1860 for a new act, to enable the company to admit the "makers of razors, files, forks, saws, edge-tools, and other articles of steel, or steel and iron combined, having a cutting edge, and manufacturers of steel." This measure is necessary to reinvigorate the company, which is the trustee of several important charities. Sheffield is well and cheaply supplied with gas and water by joint-stock companies. The relations of Sheffield to the railway system were for many years unsatisfactory. Surrounded by hills, except on the north-east, it suffered peculiar disadvantages. In 1838, the Sheffield and Rotherham line connected it with the Midland, which was soon after opened. In 1845 a line was opened from Manchester to Sheffield; and in 1849 the line was continued eastward to New Holland, on the Humber, and Grimsby, on the Lincolnshire coast. Till 1857 this line was allied to the London and North-Western, but in that year a treaty was made with the Great Northern, which thus obtained access to Manchester, and put Sheffield on a main line from that town to London. Out of this change of policy arose the memorable war of 1857–8 between the London and North-Western and the Great Northern. By the South Yorkshire Railway, Sheffield has connection with Barnsley, Doncaster, and Goole; and by the canal made in 1818, now in the hands of this company, it has water communication with the Humber. The old private banks of Sheffield have been replaced by joint-stock companies. Freehold land societies, formed to purchase estates, and divide them in allotments among thriving artisans and small tradesmen, were introduced here in 1849, and have been very successful. Up to 1858 these societies had purchased thirty estates, containing 477 acres, for L.96,000. They had spent in drains, roads, and fencing, about L.29,700, and in buildings about L.130,000. They had formed 2600 allotments, at an average cost of L.48. Upwards of seventy acres more have since been purchased. The present value of the allotments, with the buildings upon them, is estimated at L.400,000.

Sheffield is rather behind other large towns in facilities for the amusement and recreation of the inhabitants. There is great want of a capacious public hall for the holding of important meetings and for popular concerts. The town-hall, built fifty years ago, is inadequate to the present necessities of the town. The corporation, instead of erecting a hall, have rented the old assembly rooms. The botanical gardens, consisting of eighteen acres, beautifully situated, are well maintained. The Duke of Norfolk has laid out a park on the east side of the town for the benefit of the public.

The benevolent institutions of the town are well sustained. The infirmary, opened in 1797, has been considerably enlarged. Hospital wards have this year (1859) been added to the public dispensary. The Shrewsbury Hospital, opened in 1673, the Hollis' Hospital of 1703, and the Licensed Victuallers' Asylum of 1848, afford refuge for decayed and deserving old people. The Deakin institution, established in 1852, grants pensions to unmarried females above forty years of age, and has conferred a great boon on a number of ladies reduced to very deplorable circumstances. The savings bank has made moderate progress, and is well managed. In 1832, its deposits were L.89,085; in 1836, L.147,136; in 1858, L.276,738.

During the last thirty years the social habits of the town have greatly changed. It has become the custom of nearly all the manufacturers and richer tradesmen to reside in the suburbs, and luxury has immensely increased. The streets in the centre of the town are now thronged with cabs, omnibuses, and other vehicles, but they still remain narrow, crooked, and steep, as they were fifty years ago. In 1852,

Sheffield.

an act was obtained, under which several much-needed bridges, with approaches, have been made, and a rate at 3d. in the pound is expected to defray the cost in from twenty to thirty years. Two attempts to obtain an act of parliament to improve the town in sanitary and other arrangements, have been defeated by popular hostility. Sheffield is well situated for drainage, but as no power exists to make drains on a comprehensive plan, independently of township boundaries, each township pours its separate contribution into the rivers flowing through the town, by which they are rendered very pernicious and offensive.

In regard to the sanitary state of Sheffield, we are indebted for the following particulars to C. J. Shearman, Esq., M.D., who has been engaged in elaborate investigations on the subject:—

According to the returns of the Registrar-General, the gross mortality of Sheffield is 1 to each 27 of the population, male and female; whereas the normal mortality of England, when free from pre-disposing causes of disease, is 1 in 17. One great cause of this increase of mortality is the prevalence of children's diseases. The mortality of males and females per cent. at each age, calculated for the 7 years 1848–54 inclusive, is below:—

Males.			Females.		
Ages.	Sheffield.	England.	Ages.	Sheffield.	England.
5	1·196	·925	5	1·166	·922
10	·6546	·514	10	·4528	·535
15	1·557	·822	15	1·286	·851
25	·986	·997	25	1·015	1·051
35	1·311	1·260	35	1·390	1·274
45	2·093	1·839	45	1·699	1·589
55	3·502	3·190	55	2·651	2·834
65	6·618	6·721	65	5·172	6·026
75	11·401	14·696	75	9·312	13·446
85	22·03	30·202	85	13·63	27·917
95 and over	...	46·169	95 and over	15·55	45·200

The mortality of children's diseases for the same years being to 100 population—

Smallpox	·07	Hooping cough	·09	Water on the brain	·08
Measles	·11	Croup	·03		
Scarlet fever	·17	Diarrhœa	·03	Scrofula	·008

The births for the same years were in the proportion of 1 to each 24 of the population annually.

From the returns of the Registrar of Sheffield (arranged through the kind permission of the Registrar-General), the following results are deduced as to the mortality in 81 occupations, the majority of which are peculiar to Sheffield:—

Mortality per cent. of out-door heavy occupations	1·5
" " " light "	1·82
" " in-door heavy "	1·18
" " " light "	1·84
" " masons and bricklayers	1·5
" " file-cutters	1·98
" " cutlers, fitters, bench-work tailors, shoemakers, &c.	1·72
" " merchants, manufacturers, and gentlemen	2·9
" " labourers	5·0
" " grinders	4·7

The grinders suffer markedly from diseases of the lungs, of which one disease has been considered peculiar to them —grinder's asthma or rot—induced by inhaling the dust from the grinding-stones. It is most prevalent among dry grinders. This affection is less common than in former years, from the dust being carried off in many factories by a fan. Bronchitis and pneumonia are the other prevailing causes of death in this class. Gentlemen suffer most from intestinal, stomach, liver, and kidney diseases; considerably less than other large towns from tubercular disease, either general or of the lungs; and are prone to the inroad of typhus and other fevers. Cutlers are much affected with diseases of the heart and inflammation of the lungs, with secondary affections of the abdomen, more particularly after the 40th year of age. They suffer less from consumptive disease, but are prone to attacks of continued and remittent fever. The other occupations carried on in shops, as fitters, engaged in brass, Britannia metal, and German silver work, &c., are especially liable to disease of the heart, apoplexy, disease of the liver, and fever; less so to consumption. File-cutters suffer little from tubercular disease of the lungs after 35 years of age; but after that time most markedly from apoplexy, pleurisy, liver disease, and secondary abdominal disease, partly induced by cutting on lead. The other occupations present no great peculiarity of inducing special diseases.

The mortality per cent. from various diseases of Sheffield for the years 1848 to 1854 is annually to the living population as follows:—

Smallpox	·076	Typhus fever	·004	Pleurisy, Pneumonia	·2
Measles	·11	Erysipelas	·008		
Scarlatina	·16	Hydrocephalus	·076	Asthma	·005
Hooping cough	·076	Tabes Mesenterica	·000	Consumptive disease of lung	·48
Croup	·036				
Thrush	·0007	Diabetes	·000		
Diarrhœa	·036	Inebria	·0007	Cardiac	·0035
Dysentery	·000	Scrofula	·004	Hepatitis	·006
Cholera	·0003	Atrophy	·022	Jaundice	·006
Influenza	·000	Quinsey	·0007	Liver disease	·02
Ague	·000	Bronchitis	·0005	Dropsy	·061
Remittent fever	·004	Hydrothera	·001		

Habits of improvidence, fostered by the high scale of wages, marked tendency to free living both in the operative and employer, together with a malarious character of atmosphere, are the chief agents in raising the rate of mortality in Sheffield. The state of the rivers, and the proximity of some of the reservoirs which supply the town, furnish the latter element of disease. The great proportion of publicans to the population (1 to 142 over 20 years of age) is an indication of the state of supply and demand of this agent of disease.

The chief book of authority on the history, antiquities, &c., of Sheffield is *The History of Hallamshire*, by the Rev. Joseph Hunter, F.S.A., published in folio in 1819. (R. L.)

SHEFFIELD, John, *Duke of Buckinghamshire*, an eminent statesman, poet, and wit of England, was born in 1649. He lost his father at nine years of age; and his mother having married again, the care of his education was left entirely to a governor, who did not greatly improve him in his studies. Finding that he was deficient in many parts of literature, he resolved to devote a certain number of hours every day to his studies, and thereby improve himself to the degree of learning which he afterwards attained. Though possessed of a good estate, he did not abandon himself to pleasure and indolence, but entered as a volunteer in the second Dutch war, and was in that famous naval engagement where the Duke of York commanded as admiral; upon which occasion his lordship behaved so gallantly, that he was appointed commander of the Royal Catherine. He afterwards made a campaign in the French service under M. de Turenne. As Tangier was in danger of being taken by the Moors, he offered to head the forces which were sent to defend it, and accordingly was appointed to command them. He was then Earl of Mulgrave, and one of the lords of the bed-chamber to Charles II. The Moors retired on the approach of his Majesty's forces; and the result of the expedition was the blowing up of Tangier. He continued in several great posts during the short reign of James II., till that unfortunate prince was dethroned. Lord Mulgrave, though he paid his respects to King William before he was advanced to the throne, yet did not ac-

cept of any post in the government until some years afterwards. In the sixth year of William and Mary he was created Marquis of Normandy in the county of Lincoln. He was one of the most active and zealous opponents of the bill which took away Sir John Fenwick's life; and exerted the utmost vigour in carrying through the Treason Bill, and the bill for Triennial Parliaments. He enjoyed some considerable posts under King William, and possessed much of his favour and confidence. In 1702 he was sworn lord privy-seal; and in the same year was appointed one of the commissioners to treat of an union between England and Scotland. In 1703 he was created Duke of Normandy, and soon after Duke of Buckinghamshire. In 1711 he was made steward of her Majesty's household and president of the council. During Queen Anne's reign he was but once out of employment; and then he voluntarily resigned, being a confirmed Tory. Her Majesty offered to make him lord chancellor, but he declined the office. He was instrumental in the change of the ministry in 1710. A circumstance that reflects the highest honour on him, is the vigour with which he acted in favour of the unhappy Catalans, who were afterwards so inhumanly sacrificed. He died in 1721.

He was thrice married. By his two first wives he had no children; by his third, who was a daughter of King James by the Countess of Dorchester, and the widow of the Earl of Anglesey; he had besides other children, who died young, a son born in 1716, and who died at Rome in 1735, and put an end to the line of Sheffield. He was admired by the poets of his age; by Dryden, Pope, Prior, and Garth. His *Essay on Poetry* was applauded by Addison, and his *Rehearsal* is still read with pleasure. His writings were splendidly printed in 1723, in two volumes 4to, and have since been reprinted in 1729, in two volumes 8vo. The first contains his poems on various subjects; the second, his prose works, consisting of historical memoirs, speeches in Parliament, characters, dialogues, critical observations, essays, and letters. It may be proper to observe, that the edition of 1729 is castrated, some particulars relating to the revolution having given offence. Dr Johnson remarks on Sheffield, that " criticism is no longer softened by his bounties or awed by his splendour, and being able to take a more steady view, discovers him to be a writer that sometimes glimmers but rarely shines, feebly laborious, and at best but pretty. His songs are upon common topics; he mopes and grieves, and repents and despairs, and rejoices, like any other maker of little stanzas; to be great he hardly tries; to be gay is hardly in his power. . . . His verses are often insipid, but his memoirs are lively and agreeable; he had the perspicuity and elegance of an historian, but not the fire and fancy of a poet." (Cunningham's edition of Johnson's *Lives of the Poets*, 1854.)

SHEHR, a seaport on the south-east coast of Arabia, 32 miles E.N.E. of Makallah; N. Lat. 14. 43., E. Long. 49. 40. It stretches about a mile along the shore, and consists of houses, for the most part large and good, irregularly grouped together. The chief buildings are a castle, where a sultan resides, a custom-house, and several mosques. Coarse cotton-cloth, gunpowder, and arms are manufactured here; and a considerable trade is carried on. There is an open roadstead about a mile from the shore, with good anchorage. Pop. 6000.

SHEIL, Richard Lalor, the son of Edward Sheil, who, in his early years, had made a considerable fortune as a merchant at Cadiz, was born on the 17th of August 1791, at Drumdowney, a small country house, then occupied by his family previously to the completion of Bellevue, near Waterford, which his father had recently purchased. The home of the childhood of Sheil was situated amid charming scenery, on the left bank of the Suir. On the mind of the moody and imaginative boy it made a deep and lasting impression. His first instructions were received in French and Latin from a French Abbé; and he was subsequently conducted to Kensington-House School, London, an institution, presided over by Monsieur le Prince de Broglie, for the children of French refugees. Having spent some short time here, where the instruction was miserably defective, he next proceeded to a Jesuit school at Stoneyhurst, near Clitheroe in Lancashire, on the 24th of October 1804. Here he soon rose to a distinguished position in the school, and seems even then to have formed plans for his future conduct, which implied either a strong natural disposition to dramatic oratory, or an eminent degree of quickness and sagacity in divining where the power of the public speaker lay. In recitation, it was observed, he displayed singular flexibility of intonation, and a matchless ear for rhythm; but laboured under the almost insuperable difficulty, and one from which he never recovered, of having a sharp, squeaking, tuneless voice. He left Stoneyhurst in 1807, and entered Trinity College, Dublin, and subsequently resolved to study for the bar. Meanwhile his father had been ruined by commercial speculations, and his family had removed to Dublin. He took his degree of bachelor of arts in July 1811, and shortly after entered Lincoln's Inn, recently opened to Roman Catholics, to study for the Irish bar. Sheil was a leader in all public societies, both in Dublin and London, constantly declaiming or debating, according to the temper of those among whom he moved. His speeches were more noted for their gorgeous display of imagination than for the harder elements of argument; but the forensic club of Lincoln's Inn did much to correct this extravagant tendency in the young Irish lawyer. One catches a glimpse of a very attractive speech, delivered by Sheil about this time, on the side of the Vetoists, in O'Connell's rude castigation of it, when that brilliant speaker "rose to unravel the flimsy web of sophistry which was hid beneath the tinsel glare of meretricious ornament." Making allowance for the rhetorical tricks in which the great " Agitator" was fond of indulging, this criticism at least lays bare, in a somewhat rough manner, the darling sin of Sheil's early days of speech-making.

Richard Sheil was called to the bar in 1814, and contrived to eke out his scanty revenue by writing some really successful dramas. These were, *Adelaide*, 1816; the *Apostate*, 1817; *Bellamira*, 1818; *Evadne*, a rifacimento of Shirley's *Traitor*, 1819; *Montoni*, 1820; and *The Huguenot*, 1822, the last and the best of his dramatic compositions, but which met with almost total neglect. Could this be accounted for by the absence of the popular actress, Miss O'Neil? At all events, she had appeared hitherto in all Sheil's former dramas, and was only withheld from representing her part in the *Huguenot* by her marriage with Sir William Beecher. This was the opinion of Mr Macready, who sustained his part in this play with his accustomed *eclât*. It was the last dramatic composition in which Sheil indulged. Henceforward he devoted his spare energies to the more remunerative walk of politico-religious agitation.

In the year 1822 appeared the first of those well-known *Sketches of the Irish Bar*, which came out in the *New Monthly Magazine*, then conducted by the poet Campbell. These *Sketches* have since been published, in 2 vols., 1855. Here Sheil achieved a considerable literary reputation; and one can hardly help regretting that so little of the energy of a very superior mind should have been given to what, in the long run, would have proved a more remunerative expenditure for the resources of his genius than the business of an agitator, however successful. But he was possibly compelled, both from temperament and from necessity, to think more of the "bubble reputation" of the hour, than of the slower but more enduring fame which attends all the permanent productions of an exalted mind.

Sheil.

In keen observation, in subtle sensibility, in high imagination, and in acute analysis, these *Sketches* found few equals among the best productions of the day. They are doubtless tinctured, sometimes, too largely with a tendency to extravagance, both in conception and in expression; but the luxuriance is always kept in such fine proportion and subordination to the whole picture, and the idealization is constantly so elevated and grand, that the reader, although finding, on reflection, that it is not all real, is disposed to pardon the writer who has ministered so largely to his enjoyment, by presenting him with a series of dazzling delineations of the passing life and manners of the time. Sheil became a member of the Catholic Association in 1822, and three years afterwards was chosen, in conjunction with O'Connell, to plead at the bar of the House of Commons against the bill introduced for its suppression. The bill was passed into law; and the more incautious of the agitators became so violent in their oratorical zeal, that a prosecution of Sheil ensued, on a charge of having uttered seditious language. This prosecution was suddenly put an end to by the elevation of Mr Canning to the premiership. In the month of June 1827 Sheil received a severe fracture of the leg, caused by a fall from his horse, which confined him to his room for a considerable time. For the past three or four years he had familiarized himself to the Irish people. There had scarcely been a political meeting of any note, all over the country, from Sligo to the Boyne, that had not been inflamed by his speeches. He addressed meetings at night, he declaimed to assemblages by day, he harangued the electors of Clare to choose O'Connell for their representative. Ere the election week was over, the "Agitator" was returned by an immense majority; the wild huzzas of the peasants and the soldiery from the swarming hillsides adjoining rending the still July air, as a signalling of the triumph of what lay near to their hearts. The 24th of October 1828 has likewise to be recorded as one of those occasions on which Richard Sheil gained one of his oratorical triumphs. The meeting was held at Penenden Heath, in Kent, to petition against the passing of the Emancipation Bill; and of Sheil's appearance on that occasion Bentham said, "So masterly an union of logic and rhetoric as Mr Sheil's speech scarcely have I ever beheld." By the year 1829 he had attained considerable eminence at the bar, and next year he received his silk gown. On the 20th July of the same year he contracted a second marriage with Anastasia Laalor, the widow of Mr. Power of Waterford, and from whom he acquired the addition of Lalor to his name, and a considerable addition to his means. Early in the year 1830 Lord Anglesea, then Lord-Lieutenant of Ireland, wrote to Sheil, informing him that he might be returned for Milborne Port, in Dorsetshire. He readily embraced the offer; the long day-dream of his whole life was now to be fulfilled. The eloquent sarcasm and badinage of the agitator was now to be exchanged for the more peaceful and direct, if not less striking, manœuvring of facts to suit the humour of the House. Nature, as has been already said, had been scrimp enough in her justice to Sheil as an orator. Yet Christopher North, in one of his *Noctes Ambrosianæ* (for Aug. 1831), in which he, as usual, abuses those who were not of his own party, says of the Irish orator on his appearance in the House, "Nature has given him as fine a pair of eyes as ever graced human head,—large, deeply set, dark, liquid, flashing like gems, and these fix you like a basilisk, so that you forget everything else about him." Sheil rapidly rose to be one of the foremost speakers in the House of Commons. Except Lord Stanley (now Lord Derby), for Macaulay was then absent in India, he might fairly be said to be without an oratorical rival in the House. Cobden, speaking of the vehemence of his manner, the intensity of his look, and his dramatic power of intonation, in 1842, said, "It was not like any other man I had ever heard making a speech; he seemed to me like one possessed." After the passing of the Reform Act, Sheil had at first refused, but finally consented, to join O'Connell in the repeal agitation. In December 1832, he took his seat for the county of Tipperary, having previously occupied that of Louth. In 1838 he was offered office by the Melbourne administration, and accepted a commissionership of Greenwich Hospital. Henceforward there was no more talk of repeal by him. Next year he was made vice-president of the Board of Trade, and was sworn into the Privy Council. He became Judge-Advocate-General in 1841, when he exchanged Tipperary for Dungarvan. On the advent of Lord John Russell to the premiership in 1846, Sheil was chosen Master of the Mint, a post which he held till November 1850, when he accepted the post of British ambassador to the court of Tuscany, and closed his parliamentary career. For twenty years he had occupied a prominent place in all the controversies of the state. Nearly all the principles for which he had contended had now become law; and the clouds which had gathered angrily in the political heavens when he commenced his career, had now shed away, and he could, in the calm sunset of his days, enjoy the glorious light as it fell soft and rosy over the landscape. But he had to take the prospect for the realization. He had been for many years troubled with the gout, and had taken to colchicum as an emollient of pain. The death of his own son sometime before, and the sad death of his step-son, all combined with this treacherous antidote to prey upon his health. He died at Florence of an attack of gout in the stomach, on the 23d of May 1851, in his fifty-ninth year. (See *Memoirs of the Right Honourable Richard Lalor Sheil*, by W. T. M'Cullagh, 2 vols., 1855.)

Shekel || Shelley.

SHEKEL, the name of a weight and coin current among the ancient Jews. Dr Arbuthnot makes the weight of the shekel equal to 9 pennyweights 2¼ grains troy weight, and the value of the silver coin equal to 2s. 3⅜d. sterling. The golden shekel is supposed to have been worth L.1, 16s. 6d.

SHELBURNE, Earl of. See Great Britain, Reign of George III.

SHELDON, Gilbert, Archbishop of Canterbury, was born on the 19th of July 1598, at Stanton, in Staffordshire. He was admitted into Trinity College, Oxford, in 1613, and obtained his degree of M.A. in May 28th, 1620. He was chosen fellow of All Souls' College, in 1622, and taking holy orders, he became domestic chaplain to Lord Coventry. Sheldon rose through successive stages of preferment, till at last he was appointed Archbishop of Canterbury. He died, enormously rich, on the 9th of November 1677. Besides building the theatre which still bears his name at Oxford, in 1699, he is said to have expended very large sums on charitable purposes.

SHELLEY, Percy Bysshe. Whatever opinion may be held with regard to the relative position occupied by Shelley as a poet, it will be granted by most of those who have studied his writings, that they are of such an individual and original kind, that he can neither be hidden in the shade, nor lost in the brightness, of any other poet. No idea of his works could be conveyed by instituting a comparison, for he does not sufficiently resemble any other among English writers to make such a comparison possible.

Percy Bysshe Shelley was born at Field Place, near Horsham, in the county of Sussex, on the 4th of August 1792. He was the son of Timothy Shelley, Esq., and grandson of Sir Bysshe Shelley, the first baronet. His ancestors had long been large landed proprietors in Sussex.

As a child his habits were noticeable. He was especially fond of rambling by moonlight, of inventing wonderful tales, of occupying himself with strange, and sometimes dangerous, amusements. At the age of thirteen he went to Eton. In this little world, that determined opposition to whatever appeared to him an invasion of human rights and

liberty, which was afterwards the animating principle of most of his writings, was first roused in the mind of Shelley. Were we not aware of far keener distress which he afterwards endured from yet greater injustice, we might suppose that the sufferings he had to bear from placing himself in opposition to the custom of the school, by refusing to fag, had made him morbidly sensitive on the point of liberty. At a time, however, when freedom of speech, as indicating freedom of thought, was especially obnoxious to established authorities; when no allowance could be made on the score of youth, still less on that of individual peculiarity, Shelley became a student at Oxford. He was then eighteen. Devoted to metaphysical speculation, and especially fond of logical discussion, he, in his first year, printed and distributed among the authorities and members of his college a pamphlet, if that can be called a pamphlet which consisted only of two pages, in which he opposed the usual arguments for the existence of a Deity; arguments which, perhaps, the most ardent believers have equally considered inconclusive. Whether Shelley wrote this pamphlet as an embodiment of his own opinions, or merely as a logical confutation of certain arguments, the mode of procedure adopted with him was certainly not one which necessarily resulted from the position of those to whose care the education of his opinions was entrusted. Without waiting to be assured that he was the author, and satisfying themselves with his refusal to answer when questioned as to the authorship, they handed him his sentence of expulsion, which had been already drawn up in due form.

About this time Shelley wrote, or commenced writing, *Queen Mab*, a poem which he never published, although he distributed copies amongst his friends. In after years he had such a low opinion of it in every respect, that he regretted having printed it at all; and when an edition of it was published without his consent, he applied to the Court of Chancery for an injunction to suppress it.

Shelley's opinions in politics and theology, which he appears to have been far more anxious to maintain than was consistent with the peace of the household, were peculiarly obnoxious to his father, a man as different from his son as it is possible to conceive; and his expulsion from Oxford was soon followed by exile from his home. He went to London, where, through his sisters, who were at school in the neighbourhood, he made the acquaintance of Harriet Westbrook, whom he eloped with and married, when he was nineteen and she sixteen years of age. It seems doubtful whether the attachment between them was more than the result of the reception accorded by the enthusiasm of the girl to the enthusiasm of the youth, manifesting itself in wild talk about human rights, and equally wild plans for their recovery and security. However this may be, the result was unfortunate. They wandered about England, Scotland, and Ireland, with frequent and sudden change of residence, for rather more than two years. During this time Shelley gained the friendship of some of the most eminent men of the age; of whom the one who exercised the most influence upon his character and future history was William Godwin. The instructions and expostulations of this eminent writer tended to reduce to solidity and form, the vague and extravagant opinions and projects of the youthful reformer. Shortly after the commencement of the third year of their married life, an estrangement of feeling, which had been gradually widening between them, resulted in their final separation. We are not informed as to the causes of this estrangement, further than that it seems to have been owing, in a considerable degree, to the influence of an elder sister of Mrs Shelley, who domineered over her, and whose presence became at last absolutely hateful to Shelley. His wife returned to her father's house; where, apparently about three years after, she committed suicide. There seems to have been no immediate connection between this act and any conduct of Shelley. One of his biographers informs us, that while they were living happily together, suicide was a favourite subject of speculation and conversation with Mrs Shelley.

Shortly after his first wife's death, Shelley married the daughter of William Godwin. He had lived with her almost from the date of the separation. During this time they had twice visited Switzerland. In the following year (1817), it was decreed in Chancery that Shelley was not a proper person to take charge of his two children, left by his first wife, who had lived with her till her death. The bill was filed in Chancery by their grandfather. The effects of this proceeding upon Shelley may be easily imagined. Perhaps he never recovered from them, for they were not of a nature to pass away. During this year he resided at Marlow, and wrote *The Revolt of Islam*, besides portions of other poems. In the following year (1818), he left England, not to return. The state of his health, for he had appeared to be in a consumption for some time, and the fear lest his son, by his second wife, should be taken from him, combined to induce him to take refuge in Italy from both impending evils. At Lucca he began his *Prometheus*, and wrote *Julian and Maddalo*. He moved from place to place in Italy, as he had done in his own country. Their two children dying, they were for a time left childless; but the loss of these grieved Shelley less than that of his eldest two, who were taken from him by the hand of man. In 1819, Shelley finished his *Prometheus Unbound*, writing the greater part at Rome, and completing it at Florence. In this year also he wrote his tragedy, *The Cenci*. This attracted more attention during his lifetime than any other of his works. The *Ode to a Skylark* was written at Leghorn in the spring of 1820; and in August of the same year, the *Witch of Atlas* was written, near Pisa. In the following year Shelley and Byron met at Pisa. They were a good deal together; but their friendship, although real, does not appear to have been of a very profound nature; for though unlikeness be one of the necessary elements of friendship, there are kinds of unlikeness which will not harmonize. During all this time, he was not only maligned by unknown enemies, and abused by anonymous writers, but attempts of other kinds are said to have been made to render his life as uncomfortable as possible. There are grounds, however, for doubting whether Shelley was not subject to a kind of monomania upon this and similar points. In 1821, he wrote his *Adonais*, a monody on the death of Keats. Part of this poem had its origin in the mistaken notion, that the illness and death of Keats were caused by a brutal criticism of his *Endymion*, which appeared in the *Quarterly Review*. The last verse of the *Adonais* seems almost prophetic of his own end. Passionately fond of boating, he and a friend of his, Mr Williams, united in constructing a boat of a peculiar build, a very fast sailer, but difficult to manage. On the 8th of July, 1822, Shelley and his friend Williams sailed from Leghorn for Lerici, on the Bay of Spezia, near which lay his home for the time. A sudden squall came on, and their boat disappeared. The bodies of the two friends were cast on shore; and, according to quarantine regulations, were burned to ashes. Lord Byron, Leigh Hunt, and Mr Trelawney, were present when the body of Shelley was burned; so that his ashes were saved, and buried in the Protestant burial-ground at Rome, near the grave of Keats, who had been laid there in the spring of the preceding year. *Cor Cordium* were the words inscribed by his widow on the tomb of the poet.

The character of Shelley has been sadly maligned. Whatever faults he may have committed against society, they were not the result of sensuality. One of his biographers, who was his companion at Oxford, and who does not seem inclined to do him *more* than justice, asserts that

while there his conduct was immaculate. The whole picture he gives of the youth, makes it easy to believe this. To discuss the moral question involved in one part of his history would be out of place here; but even on the supposition that a man's conduct is altogether inexcusable in individual instances, there is the more need that nothing but the truth should be said concerning that, and other portions thereof. And whatever society may have thought itself justified in making subject of reprobation, it must be remembered that Shelley was under less obligation to society than most men. Yet his heart seemed full of love to his kind; and the distress which the oppression of others caused him, was the source of much of that wild denunciation which exposed him to the contempt and hatred of those who were rendered uncomfortable by his unsparing and indiscriminating anathemas. In private, he was beloved by all who knew him; a steady, generous, self-denying friend, not only to those who moved in his own circle, but to all who were brought within the reach of any aid he could bestow. To the poor he was a true and laborious benefactor. That man must have been good to whom the heart of his widow returns with such earnest devotion and thankfulness in the recollection of the past, and such fond hope for the future, as are manifested by Mrs Shelley in those extracts from her private journal given us by Lady Shelley.

As regards his religious opinions, one of the thoughts which most strongly suggest themselves is,—how ill he must have been instructed in the principles of Christianity! He says himself in a letter to Godwin, "I have known no tutor or adviser (*not excepting my father*) from whose lessons and suggestions I have not recoiled with disgust." So far is he from being an opponent of Christianity properly so called, that one can hardly help feeling what a Christian he would have been, could he but have seen Christianity in any other way than through the traditional and practical misrepresentations of it which surrounded him. All his attacks on Christianity are, in reality, directed against evils to which the true doctrines of Christianity are more opposed than those of Shelley could possibly be. How far he was excusable in giving the name of Christianity to what he might have seen to be only a miserable perversion of it, is another question, and one which hardly admits of discussion here. It was in the *name* of Christianity, however, that the worst injuries of which he had to complain were inflicted upon him. Coming out of the cathedral at Pisa one day,[1] Shelley warmly assented to a remark of Leigh Hunt, "that a divine religion might be found out, if charity were really made the principle of it instead of faith." Surely the founders of Christianity, even when they magnified faith, intended thereby a spiritual condition, of which the central principle is coincident with charity. Shelley's own feelings towards others, as judged from his poetry, seem to be tinctured with the very essence of Christianity.[2] He did not, at one time at least, believe that we could know the source of our being; and seemed to take it as a self-evident truth, that the Creator could not be like the creature. But it seems injustice to fix upon any utterance of opinion, and regard it as the religion of a man who died in his thirtieth year, and whose habits of thinking were such, that his opinions must have been in a state of constant change. Coleridge says in a letter: "His (Shelley's) discussions, tending towards atheism of a certain sort, would not have scared *me;* for *me* it would have been a semi-transparent larva, soon to be sloughed, and through which I should have seen the true *image*—the final metamorphosis. Besides, I have ever thought that sort of atheism the next best religion to Christianity; nor does the better faith I have learned from Paul and John interfere with the cordial reverence I feel for Benedict Spinoza."

Shelley's favourite study was metaphysics. The more impulse there is in any direction, the more education and experience are necessary to balance that impulse: one cannot help thinking that Shelley's *taste* for exercises of this kind was developed more rapidly than the corresponding *power*. His favourite physical studies were chemistry and electricity. With these he occupied himself from his childhood; apparently, however, with more delight in the experiments themselves, than interest in the general conclusions to be arrived at by means of them. In the imbodiment of his metaphysical ideas in poetry, the influence of these studies seems to appear. For the forms chosen are of an external physical kind, belonging, in their association with the idea, to the realm of the fancy, rather than chosen by the imaginative power, because of an inward vital resemblance. Logic had considerable attractions for him. To geometry and mathematics he was quite indifferent. One of his biographers states, that "he was neglectful of flowers," because he had no interest in botany; but one who derived such full delight from the contemplation of their external forms, could hardly be expected to feel very strongly the impulse to dissect and explore. He derived exceeding pleasure from Greek literature, especially from the works of Plato.

Several little peculiarities in Shelley's tastes are worth mentioning, because, although in themselves insignificant, they seem to correspond with the nature of his poetry. Perhaps the most prominent of these was his passion for boat-sailing. He could not pass any piece of water without launching upon it a number of boats, constructed from what paper he could find in his pockets. The fly-leaves of the books he was in the habit of carrying with him, for he was constantly reading, often went to this end. He would watch the fate of these boats with the utmost interest, till they sank or reached the opposite side. He was just as fond of real boating, and that frequently of a dangerous kind; but it is characteristic of him, that all the boats he describes in his poems are of a fairy, fantastic sort, barely related to the boats which battle with earthly winds and waves. Pistol-shooting was also a favourite amusement. Fire-works, too, gave him great delight. Some of his habits were likewise peculiar. He was remarkably abstemious, preferring bread and raisins to anything else in the way of eating, and very seldom drinking anything stronger than water. Honey was a favourite luxury with him. While at college his biographer Hogg says he was in the habit, during the evening, of going to sleep on the rug, close to a blazing fire, heat seeming never to have other than a beneficial effect upon him. After sleeping some hours he would awake perfectly restored, and continue actively occupied till far into the morning. His whole movements are represented as rapid, hurried, and uncertain. He would appear and disappear suddenly and unexpectedly; forget appointments; burst into wild laughter, heedless of his situation, whenever anything struck him as peculiarly ludicrous. His changes of residence were most numerous, and frequently made with so much haste that whole little libraries were left behind, and often lost. He was very fond of children, and used to make humorous efforts to induce them to disclose to him the still-remembered secrets of pre-existence. He seemed to have a peculiar attraction towards the unknown, and was ready to believe there was a secret hidden, where no one

[1] From *Shelley Memorials*, edited by Lady Shelley, which the writer of this paper has principally followed in regard to the external facts of Shelley's history.

[2] His *Essay on Christianity* is full of noble views, some of which are held at the present day by some of the most earnest believers. At what time of his life it was written we are not informed; but it seems such as would insure his acceptance with any company of intelligent and devout Unitarians.

Shelley. else would have thought of one. His room, while he was at college, was in a state of indescribable confusion. Not only were all sorts of personal necessaries mingled with books and philosophical instruments, but things belonging to one department of service were not unfrequently pressed into the slavery of another. He dressed well but carelessly. In person he was tall, slender, and stooping; awkward in gait, but in manners a thorough gentleman. His complexion was delicate; his head, face, and features, remarkably small; the last not very regular, but in expression, both intellectual and moral, wonderfully beautiful. His eyes were deep blue, "of a wild, strange beauty;" his forehead high and white; his hair dark brown, curling, long, and bushy. His appearance in later life is described as singularly combining the appearances of premature age and prolonged youth.

The only art in which his taste appears to have been developed was poetry. Even in his poetry, taken as a whole, the artistic element is not generally very manifest. His earliest verses (none of which are included in his collected works) can hardly be said to be good in any sense. He seemed in these to find poetry a fitting material for the imbodiment of his ardent, hopeful, indignant thoughts and feelings; and provided he could say what he wanted to say, does not seem to have cared much about the *how*. Indeed, there is too much of this throughout his works; for if the *utterance*, instead of the *conveyance* of thought, were the object sought in art, of course, not merely imperfection of language, but absolute external unintelligibility, would be unobjectionable. But his art constantly increases with his sense of its necessity; so that the *Cenci*, which is the last work of any pretension that he wrote, is decidedly the most artistic of all. There are beautiful passages in *Queen Mab*, but it is the work of a boy-poet; and as it was all but repudiated by himself, it is not necessary to remark further upon it. *The Revolt of Islam* is a poem of twelve cantos, in the Spenserian stanza; but in all respects, except the arrangement of lines and rhymes, it, in common with all other imitations of the Spenserian stanza, has little or nothing of the spirit or individuality of that stanza. The poem is dedicated to the cause of freedom, and records the efforts, successes, defeats, and final triumphant death of two inspired champions of liberty—a youth and maiden. The adventures are marvellous, not intended to be within the bounds of probability, scarcely of possibility. There are very noble sentiments and fine passages throughout the poem. Now and then there is grandeur. But the absence of art is too evident in the fact that the meaning is often obscure; an obscurity not unfrequently occasioned by the difficulty of the stanza, which is the most difficult mode of composition in English, except the rigid sonnet. The words and forms he employs to express thought seem sometimes mechanical devices for that purpose, rather than an utterance which suggested itself naturally to a mind where the thought was vitally present. The words are more a *clothing* for the thought than an *imbodiment* of it. They do not lie near enough to the thing which is intended to be represented by them. It is, however, but just to remark, that some of the obscurity is owing to the fact, that, even with Mrs Shelley's superintendence, the works have not yet been satisfactorily edited, or at least not conducted through the press with sufficient care.

The Cenci is a very powerful tragedy, but unfitted for public representation by the horrible nature of the historical facts upon which it is founded. In the execution of it, however, Shelley has kept very much nearer to nature than in any other of his works. He has rigidly adhered to his perception of artistic propriety in respect to the dramatic utterance. It may be doubted whether there is sufficient difference between the modes of speech of the different actors in the tragedy; but it is quite possible to individualize speech far too minutely for probable nature; and in this respect, at least, Shelley has not erred. Perhaps the action of the whole is a little hurried, and a central moment of awful repose and fearful anticipation might add to the force of the tragedy. The scenes also might, perhaps, have been constructed so as to suggest more of evolution; but the central point of horror is most powerfully and delicately handled. You see a possible spiritual horror yet behind, more frightful than all that has gone before. The whole drama, indeed, is constructed around, not a prominent point, but a dim, infinitely-withdrawn, underground perspective of dismay and agony. Perhaps it detracts a little from our interest in the Lady Beatrice, that after all she should wish to live, and should seek to preserve her life by a denial of her crime. She, however, evidently justifies the denial to herself on the ground that, the deed being absolutely right, although regarded as most criminal by her judges, the only way to get true justice is to deny the fact, which, there being no guilt, she might consider as only a verbal lie. Her very purity of conscience enables her to utter this with the most absolute innocence of look, and word, and tone. This is probably a historical fact, and Shelley has to make the best of it. In the drama there is great tenderness, as well as terror; but for a full effect, one feels it desirable to be brought better acquainted with the individuals than the drama, from its want of graduation, permits. Shelley, however, was only six-and-twenty when he wrote it. He must have been attracted to the subject by its embodying the concentration of tyranny, lawlessness, and brutality in old Cenci, as opposed to, and exercised upon, an ideal loveliness and nobleness in the person of Beatrice. Shelley.

But of all Shelley's works, the *Prometheus Unbound* is that which combines the greatest amount of individual power and peculiarity. There is an airy grandeur about it, reminding one of the vast masses of cloud scattered about in broken, yet magnificently suggestive forms, all over the summer sky, after a thunderstorm. The fundamental ideas are grand; the superstructure, in many parts, so ethereal, that one hardly knows whether he is gazing on towers of solid masonry, rendered dim and unsubstantial by intervening vapour, or upon the golden turrets of cloudland, themselves born of the mist which surrounds them with a halo of glory. The beings of Greek mythology are idealized and etherealized by the new souls which he puts into them, making them think his thoughts and say his words. In reading this, as in reading most of his poetry, we feel that, unable to cope with the evils and wrongs of the world as it and they are, he constructs a new universe, wherein he may rule according to his will; and a good will in the main it is—good always in intent, good generally in form and utterance. Of the wrongs which Shelley endured from the collision and resulting conflict between his lawless goodness and the lawful wickedness of those in authority, this is one of the greatest,—that during the right period of pupillage, he was driven from the place of learning, cast on his own mental resources long before those resources were sufficient for his support, and irritated against the purest imbodiment of good by the harsh treatment he received under its name. If that reverence which was far from wanting to his nature, had been but presented, in the person of some guide to his spiritual being, with an object worthy of its homage and trust, it is probable that the yet free and noble result of Shelley's individuality would have been presented to the world in a form which, while it attracted still only the few, would not have repelled the many; at least, not by such things as were merely accidental in their association with his earnest desires and efforts for the wellbeing of humanity.

That which chiefly distinguishes Shelley from other writers is the unequalled exuberance of his fancy. The reader, say for instance in that fantastically brilliant poem, *The Witch of Atlas*, the work of three days, is overwhelmed

in a storm, as it were, of rainbow snow-flakes, and many-coloured lightnings, accompanied ever by "a low melodious thunder." The evidences of pure imagination in his writings are unfrequent as compared with those of fancy: there are not half the instances of the direct imbodiment of idea in form, that there are of the presentation of strange resemblances between external things.

One of the finest short specimens of Shelley's peculiar mode is his *Ode to the West Wind*, full of mysterious melody of thought and sound. But of all his poems, the most popular, and deservedly so, is the *Skylark*. Perhaps the *Cloud* may contest it with the *Skylark* in regard to popular favour; but the *Cloud*, although full of beautiful words and fantastic cloud-like images, is, after all, principally a work of the fancy; while the *Skylark*, though even in it fancy predominates over imagination in the visual images, forms, as a whole, a lovely, true, individual work of art; a *lyric* not unworthy of the *lark*, which Mason apostrophises as "sweet feathered lyric." The strain of sadness which pervades it is only enough to make the song of the lark human.

In *The Sensitive Plant*, a poem full of the peculiarities of his genius, tending through a wilderness of fanciful beauties to a thicket of mystical speculation, one curious idiosyncrasy is more prominent than in any other; curious, as belonging to the poet of beauty and loveliness: it is the tendency to be fascinated by what is ugly and revolting, so that he cannot withdraw his thoughts from it till he has described it in language, powerful, it is true, and poetic, when considered as to its fitness for the desired end, but, in force of these very excellencies in the means, nearly as revolting as the objects themselves. Associated with this is the tendency to discover strangely unpleasant likenesses between things; which likenesses he is not content with seeing, but seems compelled, perhaps in order to get rid of them himself, to force upon the observation of his reader. But the admirer of Shelley is not pleased to find that one or two passages of this nature have been omitted in the last editions of his works.

Few men have been more misunderstood or misrepresented than Shelley. Doubtless this has in part been his own fault, as Coleridge implies, when he writes to this effect of him: that his horror of hypocrisy made him speak in such a wild way, that Southey (who was so much a man of forms and proprieties) was quite misled, not merely in his estimate of his worth, but in his judgment of his character. But setting aside this consideration altogether, and regarding him merely as a poet, Shelley has written verse which will last as long as the English literature lasts; valuable not only from its excellence, but from the peculiarity of its excellence. To say nothing of his noble aims and hopes, Shelley will always be admired for his sweet melodies, lovely pictures, and wild prophetic imaginings. His indignant remonstrances, intermingled with grand imprecations, burst in thunder from a heart overcharged with the love of his kind, and roused to a keener sense of all oppression by the wrongs which sought to overwhelm himself. But as he recedes further in time, and men are able to see more truly the proportions of the man, they will judge, that without having gained the rank of a great reformer, Shelley had in him that element of wide sympathy and lofty hope for his kind which is essential both to the *birth* and the subsequent *making* of the greatest of poets. (G. M'D.)

SHELLEY, *Mary Wollstonecraft Godwin*, was the daughter of the distinguished author of *Caleb Williams*, and the second wife of Percy Bysshe Shelley, and was born in 1798. Her earliest production of any note was her novel of *Frankenstein*, which was conceived in 1816 when travelling with her husband and Lord Byron among the romantic scenery of Switzerland. It is wild and improbable, yet there are many holds on human interest comprised in this wonderful story. It was at once pronounced a classic by the novel readers, but time, as it generally does, has slightly reversed this judgment. *Frankenstein*, however, with all its faults, and they belong much more to conception than construction, was undoubtedly far ahead of the frantic terrors excited by Mrs Radcliffe, or the coarse and horrible delineations in which Maturin delighted to indulge his readers. Mrs Shelley did not again tempt the public for many years with the products of her fantastic genius. Her care for her husband was tender and ceaseless, and she had just published her *Valperga*, a novel, when the news of his death reached her. She subsequently wrote *Falkland*, *The Last Man*, *Lodore*, and the *Fortunes of Perkin Warbeck*, but much of her inspiration had flown with the death of Shelley. She likewise wrote a pleasing account of her *Rambles in Germany and Italy*; and in 1839 she published an edition of her husband's poems, and the following year this was followed up by a selection from his letters, and a few specimens of his prose writings. She died in London on the 1st of February 1851.

SHENDY, a town of Nubia, on the right bank of the Nile, 529 miles S. of Assuan, on the borders of Upper Egypt, and 207 N. of Sennaar; N. Lat. 16. 38., E. Long. 33. 15. It was formerly a place of much importance, having been the capital of the region that anciently formed the celebrated state of Meroe, and containing a population of 50,000; but it was laid waste by the Egyptian forces in 1822, and has never since recovered its former prosperity. The place now consists of a mere collection of mud huts, and has no buildings of any importance. Some trade is still carried on. European wares are imported through Egypt, and coffee from Abyssinia; while slaves and cattle are exported to Egypt. The population has now dwindled to about 4000.

SHEN-SI, a province of China, lying between N. Lat. 32. and 39. 30., E. Long. 106. and 111.; bounded on the N. by Mongolia, from which it is separated by the Great Wall, E. by the provinces of Shan-si and Honan, S. by those of Hou-pe and Se-chuen, and W. by that of Kan-su. Area, 67,504 square miles. Most of the surface is hilly; for in the south the Peh-ling range, between the valleys of the Hoang-ho and Yang-tze-keang, traverses the country; while in the north the ground is less elevated, and has a general slope towards the east. The principal river is the Hoang-ho, which flows along the eastern boundary of the province. It receives here several affluents of considerable size, such as the Loh, Wu-ting, and Wei-ho. The southern portion of the province is watered by several affluents of the Yang-tze-keang. Shen-si is not so productive as some of the other Chinese provinces. It yields wheat, millet, musk, rhubarb, cinnabar, lead, woollen fabrics, &c. The capital is Se-gan-foo, which was for a long time the metropolis of China. Pop. (1812) 10,207,256; (1843) 10,500,000.

SHENSTONE, WILLIAM, an admired English poet, the eldest son of a plain country gentleman, who farmed his own estate in Shropshire, was born at Leasowes in November 1714. He learned to read of an old dame, whom his poem of the *Schoolmistress* has delivered to posterity; and he soon received such delight from books, that he was always calling for new entertainment, and expected that, when any of the family went to market, a new book should be brought him. As he grew older, he went for a while to the grammar-school in Hales-Owen, and was placed afterwards with an eminent schoolmaster at Solihull, where he distinguished himself by the quickness of his progress. From school he was sent, in 1732, to Pembroke College, Oxford, where he continued his name for ten years, though he took no degree. After the first four years he put on the civilian's gown, but without showing any intention to engage in the profession. At Oxford he applied to

English poetry, and in 1737 published a small *Miscellany*, without his name. He published, in 1741, his *Judgment of Hercules*, addressed to Mr Lyttleton, whose interest he supported with great warmth at an election. This was afterwards followed by the *Schoolmistress* in 1742, unquestionably Shenstone's best poem. Gray said of it, in a letter to Walpole, that it was "excellent of its kind, and masterly." Now began his delight in rural pleasures, and his passion for rural elegance; but in time his expenses occasioned clamours that overpowered the bleat of the lamb and the song of the linnet, and his groves were haunted by beings very different from fauns or fairies. He spent his estate in adorning it, and his death was probably hastened by his anxieties. It is said, that if he had lived a little longer, he would have been assisted by a pension. He died at the Leasowes, of a putrid fever, on the 11th of February 1763.

In his private opinions Shenstone adhered to no particular sect, and hated all religious disputes. Tenderness, in every sense of the word, was his peculiar characteristic; and his friends, domestics, and poor neighbours, daily experienced the effects of his benevolence. This virtue he carried to an excess that seemed to border upon weakness; yet if any of his friends treated him ungenerously, he was not easily reconciled. On such occasions, however, he used to say, "I never will be a revengeful enemy; but I cannot, it is not in my nature, to be half a friend." If we consider the perfect paradise into which he had converted his estate, the hospitality with which he lived, his charities to the indigent, and all out of an estate that did not exceed L.300 a-year, one should rather wonder that he left anything behind him, than blame his want of economy. He yet left more than sufficient to pay all his debts, and by his will appropriated his whole estate to that purpose. Shenstone never married. His works have been published by Dodsley, in three volumes 8vo. The first volume contains his poetical works, which are particularly distinguished by an amiable elegance and beautiful simplicity; the second volume contains his prose works; the third his letters and other pieces. His life has been written by Johnson in his *Lives of the Poets.* (See Cunningham's Edition, 1854.) There is likewise an edition of his poetical works, published in Edinburgh in 1854, with a biography.

SHEPTON-MALLET, a market-town of England, in the county of Somerset, on a small affluent of the Brue, at the eastern foot of the Mendip Hills, 4½ miles E. of Wells, and 116 W.S.W. of London. It is an ancient place, with numerous narrow lanes, and one principal street, which is broad and lined with good houses. Near the centre is a market-place, in which there is a handsome hexagonal cross of the fifteenth century. On the east side of the market-place stands the parish church, a large edifice in the form of a cross. It is in the early English style, and has a tower and spire. There are also in the town places of worship for Wesleyans, Independents, Roman Catholics, and Unitarians. A free grammar-school, founded here in 1627, had, in 1854, 50 scholars; and there is a national school, besides various similar establishments, a literary institution, and almshouses. Various manufactures are carried on here, employing in all about 2000 hands. Silk, velvet, crape, and ribbons are the chief articles produced. An extensive trade is carried on in corn, for which there are weekly markets. Three annual fairs are held for cattle and cheese. Pop. 3885.

SHERBET, a compound drink, first brought into England from Turkey and Persia, consisting of water, lemon-juice, and sugar, in which are dissolved perfumed cakes made of Damascus fruit, containing an infusion of some drops of rose-water to give it perfume. Another kind of sherbet is made of violets, honey, and juice of raisins.

SHERBORNE, a market-town of England, Dorsetshire, on the slope of a hill in the fertile valley of Blackmore, watered by a branch of the Yeo, 18 miles N. by W. of Dorset, and 117 S.W. by W. of London. It is compactly built, has some ancient houses, and several handsome public buildings. Among the latter is the parish church, formerly a cathedral, built at various dates, and in various styles. It has recently been restored at great expense, and it has a very fine tower in the Norman style, with a ponderous bell, presented by Cardinal Wolsey. Near the church are the handsome town-hall, the market-house, and the free grammar-school, which occupies some of the buildings of the old abbey restored. This school was founded by Edward VI., in 1550; it has an endowment of L.1000 a-year, and several exhibitions at the universities. It contained, in 1854, 109 scholars. There are various other schools in the town, also places of worship for Wesleyans, Quakers, and Independents, the last a very handsome edifice. In the vicinity stands Sherborne Lodge, or Castle, the seat of the Earl of Digby, originally built by Sir Walter Raleigh. The remains of the Castle of Sherborne, which was demolished in the time of the Commonwealth, occupy a rocky hill at the east end of the town. Many of the inhabitants are employed in sewing gloves for manufacturers in Yeovil; and there are large silk-mills, which employ a considerable number of hands. The town is ancient, having existed in the time of the Saxons, when it was the seat of a bishop, subsequently removed to Old Sarum, and still later to Salisbury. The strength of its castle made it a place of importance in the various civil wars of the middle ages. Its staple manufacture was at one time woollen cloth, after that buttons and haberdashery, now silk. Pop. 3878.

SHERBURN, a market-town of England, in the West-Riding of Yorkshire, 13 miles S.S.W. of York. It has a handsome old parish church, other places of worship for Wesleyans and Roman Catholics, a free grammar-school, national school, and others. In the neighbourhood there are orchards, stone-quarries, and flour-mills. Pop. of the parish, 3754; of the township, 1440.

SHERBURNE, Sir Edward, descended from a good family at Stainhurst in Lancashire, was born in London on the 18th September 1618. He received his early education from the celebrated Thomas Farnaby, and subsequently from Charles Aleyn. In 1640 he accomplished the grand tour, as it was called, of Europe, and returned just in time to follow his father to the grave in 1641. He was appointed to his father's office of clerk of the Ordnance, but the rebellion which subsequently ensued removed him from this post. It did more. Fastening on him as a royalist and staunch Roman Catholic, the usher of the black rod held him in durance during a long and expensive confinement. On his release he was as active as ever in behalf of the king, who appointed him commissary-general of his artillery. He fought for the king, attended him at Oxford, and he took his master's degree there in 1642. On going up to London in 1646, he was compelled to hide himself for a space about the chambers of the Middle Temple. Freed from this annoying surveillance, he was appointed by Sir George Saville, in 1651, superintendent of his affairs, and afterwards was chosen travelling tutor to Sir John Coventry. Sherburne regained his old office at the Ordnance on the Restoration, only to lose it again at the Revolution of 1688. He had been knighted in 1682; but it is to be feared his later years were clouded with poverty. In 1696 we find Sherburne presenting a supplicatory memorial to the Earl of Romney, then Master-General of the Ordnance, and an humble petition to the king. Whether any of these memorials was attended to, or whether this loyal subject was left, as thousands of others were, to drag out a life of penury, invoking the public for a bit of bread or a drop of water in the name of the king, cannot now be determined

He was compelled to observe a very strict retirement, until death, in November 4, 1702, put an end to all his sorrows. Sherburne, who had been a man of a very amiable temper, made the acquaintance of Thomas Stanley, author of the *History of Philosophy*, 1655–60, and of James Shirley, the dramatist, with whom he remained in close friendship during the rest of their lives. Sherburne translated the *Medea* (1648), and the *Troades* (1679) of Seneca. He is now best known by his version of Manilius, which contains a valuable appendix, comprising notices of the translator's contemporaries.

SHERIDAN, Frances, wife of Thomas Sheridan, was born in Ireland about the year 1724, but descended from a good English family which had removed thither. Her maiden name was Chamberlaine, and she was granddaughter of Sir Oliver Chamberlaine. The first literary performance by which she distinguished herself was a little pamphlet at the time of a violent party dispute relative to the theatre, in which Sheridan had newly embarked his fortune. So well-timed a work exciting the attention of Sheridan, he sought out his fair patroness, to whom he was soon afterwards married. She was a person of the most amiable character in every relation of life, with the most engaging manners. After lingering some years in a very weak state of health, she died at Blois, in France, in the year 1766. Her *Sidney Biddulph* attained to great popularity, and her *Nourjahad* delighted all readers of romance.

Sheridan, *Richard Brinsley*, a distinguished dramatist and politician, was born at Dublin in the month of September 1751, and baptized in St Mary's Church on the fourth of the following month. His grandfather and father each attained a celebrity, by the friendship with which the former was honoured by Swift, and by the competition, and even rivalry, which the latter so long maintained with Garrick. His mother, too, was a woman of considerable talents. Her affecting novel, Sidney Biddulph, could boast amongst its panegyrists Mr Fox and Lord North; and in the tale of Nourjahad she employed the graces of oriental fiction to deceive her readers into a taste for true happiness and virtue.

At the age of seven years, Richard Brinsley Sheridan was, with his eldest brother Charles Francis, placed under the tuition of Mr Samuel Whyte of Grafton Street, Dublin; and after being little more than a year under his care, they were removed to England, where Mr and Mrs Sheridan had lately gone to reside. In the year 1762, Richard was sent to Harrow, Charles being kept at home as a fitter subject for the instructions of the father. At that time, Dr Sumner was at the head of the school, and Dr Parr, who to the massy erudition of a former age joined the free and enlightened intelligence of the present, was one of the under masters. Both he and Dr Sumner endeavoured, by all possible means, to awaken in Sheridan a consciousness of those powers which he manifestly possessed; but remonstrance and encouragement were equally thrown away upon the good-humoured indifference of their pupil. One of the most valuable acquisitions he derived from Harrow, however, was that friendship with Dr Parr, which lasted throughout his life, and which identity of political opinion tended not a little to invigorate.

On his leaving Harrow, where he continued until about his eighteenth year, he was brought home by his father, who, with the elder son, Charles, had lately returned from France, and taken a house in London. Here the two brothers for some time received private tuition from Mr Lewis Kerr, an Irish gentleman, who had formerly practised as a physician; and they also attended the fencing and riding schools of Mr Angelo, at the same time receiving from their father instructions in English grammar and oratory. Of this advantage, however, the elder son appears alone to have availed himself; and Richard, determined to owe all to nature, was found as impracticable a pupil at home as at school. But, however inattentive to his studies he may have been at Harrow, it is evident, from a letter of his school-fellow, Mr Halhed, that he had already distinguished himself in poetry, and, in conjunction with his friend, had translated the seventh Idyl, and many of the lesser poems of Theocritus. In the year 1770, when Halhed was at Oxford, and Sheridan with his father at Bath, they commenced a correspondence (of which Halhed's share only remains), and, with all the hope and spirit of young adventurers, began and prosecuted several works, of which none but their translation of Aristænetus ever saw the light.

In this copartnership of genius, their first joint production was a play in three acts, called *Jupiter*, written in imitation of the burletta of Midas. Of this piece Halhed, who had furnished the burlesque scenes, entertained great hopes; nor were those of Sheridan less earnest and sanguine; yet that habit of dilatoriness, which is too often attendant upon genius, and which, throughout life, was remarkable in the character of Mr Sheridan, prevailed so far, that though he received from his friend the sketch of this piece in 1770, it was not till May next year that the probability of the arrival of the manuscript was announced to Mr Foote. Another of their projects was a periodical miscellany, the idea of which originated with Sheridan. The title intended by him for this paper was Hernan's Miscellany, to which Halhed objected, and proposed The Reformer, as a newer and better name. But this paper, for want of auxiliaries, never proceeded beyond the first number, which was written by Sheridan. It is the characteristic of fools to be always beginning; and this is not the only point in which folly and genius resemble each other. Amongst the many literary works projected by Sheridan at this period, were a collection of Occasional Poems, and a volume of Crazy Tales, to the former of which Halhed suggests, that "the old things they did at Harrow, out of Theocritus," might form a useful contribution. But neither of these came to any thing; and the translation of Aristænetus was the only fruit of their literary alliance that, as we have already stated, ever arrived at sufficient maturity for publication.

The passion, however, that now began to take possession of his heart was little favourable to his advancement in serious studies. In the neighbourhood of Miss Linley, the arts and the sciences were suffered to fall asleep, and even the translation of Aristænetus itself proceeded but slowly. After various fortune, however, it at length made its appearance in August 1771, contrary to the advice of the bookseller, and, as it might have been expected, from the unpropitious season at which it appeared, complete failure was the consequence. The disappointment of the authors was no doubt proportioned to the sanguine expectations they had indulged. But as to Mr Sheridan, he sought for consolation in the society of Miss Linley, who had now become the star of his attraction, and the centre round which revolved all his hopes. This lady, indeed, notwithstanding the drawback of her profession as a singer, appears to have spread her gentle conquests to an extent almost unparalleled in the annals of beauty. "Her personal charms, the exquisiteness of her musical talents, and the full light of publicity which her profession threw upon both," says Mr Moore, "naturally attracted round her a crowd of admirers, in whom the sympathy of common pursuit soon kindled into rivalry, till she became at length an object of vanity as well as of love. Her extreme youth, too (for she was little more than sixteen when Sheridan first met her), must have removed, even from minds the most fastidious and delicate, that repugnance they might have justly felt to her profession, if she had lived much longer under its tarnishing influence, or lost, by frequent exhibitions before the public, that fine gloss of feminine modesty, for whose absence not all the talents and accomplishments of the whole sex can atone."

Even at this early age, she had been on the point of marriage with Mr Long, an old gentleman of considerable fortune in Wiltshire; but, on her secretly representing to him, that she never could be happy as his wife, he generously took upon himself the whole blame of breaking off the alliance, and even indemnified the father by settling L.3000 upon his daughter. Mr Sheridan, who owed to this liberality not only the possession of the woman he loved, but the means of supporting her during the first years of their marriage, uniformly spoke of Mr Long with all the kindness and respect which such a disinterested character merited. Meanwhile, in love, as in all besides, the power of a mind like Sheridan's made itself felt through all obstacles; and he won the entire affections of the Syren, though the number and wealth of his rivals, amongst whom were a brother and friend, the ambitious views of the father, and the temptations to which she was hourly exposed, kept his fears and jealousies continually on the watch. But, whilst this was the case, a new and unexpected difficulty awaited him.

Captain Mathews, a married man, and intimate with Miss Linley's family, had for some time harassed her with those discreditable addresses, which it is equally painful to disclose and intolerable to endure. To the threat of self-destruction, he is said to have added the still more unmanly menace of ruining her reputation, if he could not undermine her virtue. Terrified by his perseverance, she confided her distresses to Sheridan, who lost no time in expostulating with him upon the cruelty, libertinism, and hopelessness of his pursuit. Such a remonstrance, however, was but little calculated to conciliate the forbearance of this professed man of gallantry; so that, early in 1772, Miss Linley adopted the resolution of flying to France, and taking refuge in a convent. At this time Sheridan was little more than twenty, and Miss Linley just entering her eighteenth year. Landing at Dunkirk, they proceeded to Lisle, where they procured an apartment in a convent, with the intention of remaining there until Sheridan should have the means of supporting her as his wife. On the first discovery of the elopement, Mathews busied himself making inquiries into the affair. During the four or five weeks that the young couple were absent, he never ceased to haunt the Sheridan family with all sorts of exaggerated rumours; and at length, urged on by the restlessness of revenge, he inserted a violent and inflammatory advertisement in the Bath Chronicle, in which he publicly posted Mr Sheridan as a scoundrel and a liar. The consequences of this were such as might have been expected. The party now returned from the Continent, and, without loss of time, Sheridan called out Mathews. His second on the occasion was Mr Ewart, and the particulars of the duel, which was fought with swords, are stated by himself in a letter addressed to Captain Knight, the second of Mathews. From this it appears that Mathews, being worsted, was obliged to beg his life; after which he signed an ample apology, in which he retracted the expressions he had made use of, as "the effects of passion and misrepresentation," and begged pardon for his advertisement in the Bath Chronicle.

With the odour of this transaction fresh about him, Mr Mathews retired to his estate in Wales, and there found himself universally shunned. An apology may be, according to circumstances, either the noblest effort of manliness, or the last resource of fear; and, from the reception which this gentleman everywhere experienced, it is evident that to the latter class of cases his late retraction had been referred. In this crisis, a Mr Barnett, who had but lately come to reside in his neighbourhood, took upon himself the duty of urging a second meeting with Sheridan, as the only means of removing the stigma left by the first; offering, at the same time, to be the bearer of the challenge. This offer was accepted, and the parties met at Kingsdown, where a desperate encounter ensued, in which Mr Sheridan's sword was broken, and himself severely wounded. A narrative of this affair, drawn up by Mr Barnett, and sanctioned by the concurrence of Captain Paumier (Sheridan's friend) in the truth of its material facts, was soon afterwards published; whilst the comments which Sheridan thought it necessary to make have been found in an unfinished state amongst his papers. As soon as Sheridan was sufficiently recovered of his wounds, his father sent him to pass some months at Waltham Abbey, Essex, where he continued, with but a few short intervals of absence, from August or September 1772, till the spring of the following year.

During this period, he evinced considerable industry, particularly in an abstract which he made of the History of England, and in a collection of remarks on Sir William Temple's works, especially his essay on Popular Discontents, on which his observations are tasteful and just. Still his situation was at this time singularly perplexing. He had won the heart, and even the hand, of the woman he loved, yet saw his hopes of possessing her farther off than ever. He had twice risked his life against an unworthy antagonist, yet found the vindication of his honour incomplete. He felt within himself all the proud consciousness of genius, yet, thrown upon the world without a profession, he looked in vain for a channel through which to direct its energies. Even the precarious hope which his father's favour held out had been purchased by an act of duplicity, which his conscience condemned; for he not only had promised that he would instantly abandon the pursuit, but had even taken an oath that he would never marry Miss Linley. To a mind so young and so ardent, the pressure of these various anxieties must, of course, have been great; in fact they could only have been adequately described by him who felt them; and there still exist some letters, written by him during this time, which betray a sadness and despondency, sometimes breaking out into aspirings of ambition, sometimes rising even into a tone of cheerfulness, that ill concealed the melancholy underneath. But it was impossible that Sheridan could be always under a cloud. Misunderstandings there no doubt were, arising probably from those paroxysms of jealousy into which he must have been continually thrown; but reconcilement was with no great difficulty effected; and at length Mr Linley, convinced that it was impossible to keep them much longer asunder, consented to their union, which took place on the 13th of April 1773.

A few weeks previous to his marriage, Sheridan had been entered a student of the Middle Temple. It was not to be expected, however, that talents like his would submit to toil for the distant and dearly-earned emoluments which a life of labour in this profession might secure; nor, indeed, did his circumstances admit of any such patient speculation. A part of the sum which Mr Long had settled upon Miss Linley, and occasional assistance from her father, were now the only resources left him, besides his own talents. Mrs Sheridan's celebrity as a singer was a ready source of wealth, and offers of the most advantageous kind were pressed upon them by the managers of concerts, both in town and country. But her husband at once rejected all thoughts of allowing her to re-appear in public, and, instead of profiting by the display of his wife's talents, adopted the manlier resolution of seeking independence by his own. How decided his mind was upon the subject, appears by a letter written to Mr Linley about a month after the marriage. At East Burnham, whence this letter is dated, they were now living in a small cottage, to which they had retired immediately on their marriage; and to it they often looked back with a sigh, in after times, when they were more prosperous and less happy. Towards winter they went to lodge for a short time with Storace, the intimate friend of Mr Linley, and in the following year attained that first step

Sheridan. towards independence, a house to themselves. During the summer of 1774, they passed some time at Mr Canning's and Lord Coventry's; but so little did these visits interfere with the literary industry of Mr Sheridan, that he had not only at that time finished his play of the Rivals, but was on the point of "sending a book to press."

On the 17th of January 1775, the comedy of the Rivals was brought out at Covent Garden. This play failed on its first representation, chiefly owing to the bad acting of Mr Lee in Sir Lucius O'Trigger. Another actor was, however, substituted in his stead, and the play being lightened of this and some other incumbrances, rose at once in public favour and patronage. The best comment on this lively play is to be found in the many smiling faces that are lighted up whenever it appears. With much less wit, it exhibits more humour than the School for Scandal, and the dialogue is more natural, as coming nearer the current of ordinary conversation. The characters, however, are not such as occur very commonly in the world, and for our knowledge of them we are indebted to their confessions rather than to their actions. Lydia Languish, in proclaiming the extravagance of her own romantic notions, prepares us for events much more ludicrous and eccentric than those in which she is concerned; in the composition of Sir Lucius O'Trigger, his love of fighting is the only characteristic strongly brought out; and the wayward, captious jealousy of Falkland, though so highly coloured in his own representation, is productive of nothing answerable to such an announcement. The character of Sir Anthony Absolute is perhaps the best sustained and most natural of any, and the scenes between him and Captain Absolute are genuinely dramatic. Mrs Malaprop's mistakes have often been objected as improbable from a woman in her rank of life; but though some of them are extravagant and farcical, they are almost all amusing; and the luckiness of her simile, "as headstrong as an *allegory* on the banks of the Nile," has been acknowledged by all whose taste is not too refined to be moved by the genuine comic.

Mr Sheridan now employed the summer recess in writing the Duenna, whilst his father-in-law, Mr Linley, assisted in selecting and composing the music for it. In hands so willing, the work made speedy progress, and, on the 21st November, the Duenna was performed at Covent Garden. The run of this opera has, we believe, no parallel in the annals of the drama. The Beggar's Opera had a career of sixty-three nights; but the Duenna, more fortunate, was acted no less than seventy-five times during the season, the only intermissions being a few days at Christmas, and the Fridays in every week. In order to counteract this great success of the rival house, Garrick found it necessary to bring forward all the weight of his best characters; and he had even recourse to the expedient of playing off the mother against the son, by reviving Mrs Frances Sheridan's comedy of the Discovery, and acting the leading character in it himself. The Duenna, in fact, is one of the very few operas in our language which combine the merits of legitimate comedy with the attractions of poetry and song. The "sovereign of the soul," as Gray calls music, always loses by being made exclusive sovereign; and the division of her empire with poetry and wit, as in the instance of the Duenna, doubles her real power. The intrigue of this piece is constructed and managed with considerable adroitness, having just material enough to form three acts, without being encumbered by too much intricacy, or weakened by too much extension. And as to the wit of the dialogue, except in one or two instances, it is of that accessible kind which lies near the surface, and which, as it is produced without effort, may be enjoyed without wonder.

Towards the close of the year 1775, Garrick intending to part with his moiety of the patent of Drury Lane theatre, and retire from the stage, Mr Sheridan made him an offer as purchaser, and eventually became patentee and manager. The progress of the negociation cannot be better related than in some of Sheridan's own letters, addressed to Mr Linley, which Mr Moore has printed. It appears, indeed, that the contract was perfected in June 1776; and in a paper drawn up by Mr Sheridan many years afterwards, the shares of the respective purchasers are thus stated, viz. Mr Sheridan, two fourteenths of the whole, L.10,000; Mr Linley, the same, L.10,000; and Dr Ford, three fourteenths, L.15,000. Whence Mr Sheridan's supply came, or to whom he was indebted for this seasonable aid, has never been known. Not even to Mr Linley, whilst entering into all other details, does he hint at the fountain-head from which it was to come; and, indeed, there was something mysterious about all his acquisitions, whether in love or in learning, in wit or in wealth. Finally, in reference to this subject, the first contribution which the new manager furnished to the stock of the theatre was an alteration of Vanburgh's comedy, the Relapse, which was brought out on the 24th of February 1777, under the title of a Trip to Scarborough.

Mr Sheridan was now approaching the summit of his dramatic fame. He had already produced the best opera in the language, and there now remained for him the glory of writing also the best comedy. As this is a species of composition which, more perhaps than any other, seems to require a knowledge of human nature and the world, it is not a little extraordinary that nearly all our first-rate comedies should have been the productions of very young men. Those of Congreve were all written before he was five-and-twenty. Farquhar produced the Constant Couple in his two-and-twentieth year, and died at thirty. Vanburgh was a young ensign when he sketched out the Relapse and the Provoked Wife; and Sheridan crowned his reputation with the School for Scandal at six-and-twenty. And it is still more remarkable to find, as in the instance before us, that works, which we might suppose to have been the offspring of a careless but vigorous fancy, should, on the contrary, have been the slow result of many doubtful experiments, gradually unfolding beauties unseen even by him who produced them, and at length arriving step by step at perfection. That the School for Scandal was produced by this tardy process, is evident from the sketches of its plan and dialogue which Mr Moore has produced, and which serve to throw a remarkable light on the first slow workings of genius, out of which its finest transmutations arise. The reader who may feel curious on this subject is referred to Mr Moore's clear and masterly exposition. Suffice it to mention, that there are two distinct sketches, in the second of which particularly, is shown the condensing process which his wit must have gone through before it attained its present proof and flavour. There appear also to have been originally two plots, which the author incorporated into one; yet, even in the details of the new plan, considerable alterations were subsequently made, entire scenes suppressed or transposed, and the dialogue of some completely rewritten.

This play was produced on the 8th of May 1777, and its success was decided and triumphant. Indeed, long after its first uninterrupted run, it continued to be played regularly two or three times a week; and on comparing the receipts of the first twelve nights with those of a later period, it will appear how little the attraction of the piece had abated by repetition. The beauties of this comedy are so universally known, that it cannot be necessary to dwell upon them. With but little interest in the plot, no very profound or ingenious development of character, and a group of personages, not one of whom has any legitimate claims upon either our affection or esteem, it yet, by the admirable skill with which its materials are managed, the happy contrivance of the situations, that perpetual play of wit which never tires, and a finish almost faultless, it unites the suffrages at once of the refined and the simple, and is not less successful in

 satisfying the tastes of the one, than in ministering to the enjoyment of the other. And this is the true triumph of genius in all the arts. In painting, sculpture, music, or literature, those works which have pleased the greatest number for the longest space of time, may be pronounced the best; for, however mediocrity may enshrine itself in the admiration of the few, the palm of excellence can only be awarded by the many. The defects of the School for Scandal, if they can be allowed to amount to defects, are in a great measure traceable to the amalgamation of two distinct plots, out of which the piece was formed. From this cause has devolved that excessive opulence with which the dialogue is almost overloaded, and which Sheridan himself used to mention as a fault which he was conscious of in his work. From beginning to end, it is a continued sparkling of point and polish; and the whole of the characters might be comprehended under one common designation of wits, even Trip, the servant, being as shining and brilliant as the rest. "In short," says Mr Moore, "the entire comedy is a sort of El Dorado of wit, where the precious metal is thrown about by all classes, as carelessly as if they had not the least idea of its value."

Soon after the appearance of this comedy, Sheridan made a further purchase of theatrical property, amounting to L.17,000; and amongst the visible signs of his increased influence in the affairs of the house, was the appointment, this year, of his father to be manager. At the beginning of the year 1779, Garrick died, and Sheridan, who had followed his body to the grave, wrote a monody to his memory, which was recited after the play in the month of March following. In the course of the same year he produced the entertainment of the Critic, which was his last legitimate offering at the shrine of the dramatic muse. In this incomparable farce, we have a striking instance of the privilege which genius assumes of taking up subjects that had passed through other hands, and giving them new value and currency. The plan of the Rehearsal was first adopted for the purpose of ridiculing Dryden; but although there is much laughable humour in some of the dialogue, the salt was not of a very conservative nature, and the piece continued to be served up to the public long after it had lost its relish. Fielding tried the same plan in a variety of productions, but without much success, except, perhaps, in the comedy of Pasquin. It was reserved for Sheridan to give vitality to this form of dramatic humour, and to invest even his satirical portraits with a generic, which, without weakening the particular resemblance, makes them representatives of the whole class to which the original belonged. Bayes, on the other hand, is a caricature made up of little more than personal peculiarities, but may amuse as long as reference may be had to the prototype, but fall lifeless the moment the individual that supplied them is no more.

Having terminated his dramatic career, in which he had been eminently successful, Sheridan now prepared to act a part in a widely different scene. His thoughts had been gradually drawn to the seducing subject of politics, on which he had tried his hand at some very fair remarks on absenteeism; he had also rendered some service to the party with which he had connected himself, by taking an active share in a periodical publication called the Englishman; and his first appearance before the public was made in conjunction with Mr Fox, at the beginning of 1780, when the Resolutions on the State of the Representation, together with a Report on the same subject, were laid before the public. The dissolution of parliament, which took place in the autumn of 1780, at length afforded the opportunity to which his ambition had so eagerly looked forward; and Stafford was destined to have the honour of first choosing him for its representative. It is not our intention, however, to investigate his political with the same minuteness as his literary life; and this is the less necessary, seeing that the amplest narrative would probably be the heaviest, and that the masterly pen of Lord Brougham has sketched an outline which must be fully sufficient to satisfy the inquiries of the most curious and inquisitive.

"His first effort," says Lord Brougham, "was unambitious, and it was unsuccessful. Aiming at but a low flight, he failed in that humble attempt. An experienced judge, Woodfall, told him it would never do; and counselled him to seek again the more congenial atmosphere of Drury Lane. But he was resolved that it should do; he had taken his part; and as he felt the matter was in him, he vowed not to desist till he had brought it out. What he wanted in acquired learning and natural quickness, he made up by indefatigable industry. Within given limits, towards a present object, no labour could daunt him; no man could work for a season with more steady and unwearied application. By constant practice in small matters, or before private committees, by diligent attendance upon all debates, by habitual intercourse with all dealers in political wares, from the chiefs of parties and their more refined coteries, to the providers of daily discussion for the public, and the chroniclers of parliamentary speeches, he trained himself to a facility of speaking, absolutely essential to all but first-rate genius, and all but necessary even to that; and he acquired what acquaintance with the science of politics he ever possessed, or his speeches ever betrayed. By these steps he rose to the rank of a first-rate speaker, and as great a debater as a want of readiness, and need for preparation, would permit.

"He had some qualities which led him to this rank, and which only required the habit of speech to bring them out into successful exhibition; a warm imagination, though more prone to repeat with variations the combinations of others, or to combine anew their creations, than to bring forth original productions; a fierce, dauntless spirit of attack; a familiarity, acquired from his dramatic studies, with the feelings of the heart and the ways to touch its chords; a facility of epigram and point, the yet more direct gift of the same theatrical apprenticeship; an excellent manner, not unconnected with that experience; and a depth of voice which perfectly suited the tone of his declamation, be it invective, or be it descriptive, or be it impassioned. His wit, derived from the same source, or sharpened by the same previous habits, was eminently brilliant, and almost always successful. It was, like all his speaking, exceedingly prepared, but it was skilfully introduced, and happily applied; and it was well mingled also with humour, occasionally descending to farce. How little it was the inspiration of the moment, all men were aware who knew his habits; but a singular proof of this was presented by Mr Moore when he came to write his life; for we there find given to the world, with a frankness which must almost have made the author shake in his grave, the secret note-books of this famous wit; and are thus enabled to trace his jokes, in embryo, with which he had so often made the walls of St Stephen's shake, in a merriment excited by the happy appearance of sudden unpremeditated effusion.

"The adroitness with which he turned to account sudden occasions of popular excitement, and often at the expense of the Whig party, generally too indifferent to such advantages, and too insensible to the damage they thus sustained in public estimation, is well known. On the mutiny in the fleet, he was beyond all question right; on the French invasion, and on the attacks upon Napoleon, he was almost as certainly wrong; but these appeals to the people, and to the national feelings of the House, tended to make the orator well received, if they added little to the statesman's reputation; and of the latter character he was not ambitious. His most celebrated speech was certainly the one upon the Begum charge, in the proceedings against Hastings; and nothing can exceed the accounts left us of

its unprecedented success. Not only the practice then first began, which has gradually increased till it greets every good speech, of cheering, on the speaker resuming his seat, but the minister besought the House to adjourn the decision of the question, as being incapacitated from forming a just judgment under the influence of such powerful eloquence; whilst all men on all sides vied with each other in extolling so wonderful a performance. Nevertheless, the opinion has now become greatly prevalent, that a portion of this success was owing to the speech having so greatly surpassed all the speaker's former efforts, to the extreme interest of the topics which the subject naturally presented, and to the artist-like elaboration and beautiful delivery of certain fine passages, rather than to the merits of the whole. Certain it is, that the repetition of great part of it, presented in the short-hand notes of the speech on the same charge, in Westminster Hall, disppoints every reader who has heard of the success which attended the earlier effort. In truth, Mr Sheridan's taste was very far from being chaste, or even moderately correct. He delighted in gaudy figures; he was attracted by glare, and cared not whether the brilliancy came from tinsel or gold, from broken glass or pure diamond; he overlaid his thoughts with epigrammatic diction; he 'played to the galleries,' and indulged them, of course, with an endless succession of claptraps. His worst passages by far were those which he evidently preferred himself, full of imagery, often far-fetched, oftener gorgeous, and loaded with point that drew the attention of the hearer away from the thoughts to the words; and his best by far were those where he declaimed, with his deep clear voice, though somewhat thick utterance, with a fierce defiance of some adversary, or an unappeasable vengeance against some oppressive act; or reasoned rapidly, in the like tone, upon some plain matter of fact, or exposed as plainly to homely ridicule some puerile sophism; and in all this his admirable manner was aided by an eye singularly piercing,[1] and a countenance which, though coarse, and even in some features gross, was yet animated and expressive, and could easily assume the figure of both rage, and menace, and scorn. The few sentences with which he thrilled the House, on the liberty of the press, in 1810, were worth, perhaps, more than all his elaborated epigrams and forced flowers on the Begum charge, or all his denunciations of Napoleon, 'whose morning orisons and evening prayers are for the conquest of England, whether he bends to the God of Battles or worships the Goddess of Reason;' certainly far better than such pictures of his power, as his having 'thrones for his watchtowers, kings for his sentinels, and for the palisades of his castle sceptres stuck with crowns.' 'Give them,' said he in 1810, and in a far higher strain of eloquence, 'a corrupt House of Lords; give them a venal House of Commons; give them a tyrannical prince; give them a truckling court,—and let me but have an unfettered press; I will defy them to encroach a hair's breadth upon the liberties of England.' Of all his speeches, there can be little doubt that the most powerful, as the most chaste, was his reply, in 1805, upon the motion which he had made for repealing the Defence Act. Mr Pitt had unwarily thrown out a sneer at his support of Mr Addington, as though it was insidious. Such a stone, cast by a person whose house, on that aspect, was one pane of glass, could not fail to call down a shower of missiles; and they who witnessed the looks and gestures of the aggressor, under the pitiless pelting of the tempest which he had provoked, represent it as certain that there were moments when he intended to fasten a personal quarrel upon the vehement and implacable declaimer.

"When the just tribute of extraordinary admiration has been bestowed upon this great orator, the whole of his praise has been exhausted. As a statesman, he is without a place in any class, or of any rank; it would be incorrect and flattering to call him a bad, or a hurtful, or a short-sighted, or a middling statesman; he was no statesman at all. As a party man, his character stood lower than it deserved, chiefly from certain personal dislikes towards him; for, with the perhaps doubtful exception of his courting popularity at his party's expense, on the two occasions already mentioned, and the much more serious charge against him of betraying his party in the Carlton House negociation of 1812, followed by his extraordinary denial of the facts when he last appeared in parliament, there can nothing be laid to his charge as inconsistent with the rules of the strictest party duty and honour; although he made as large sacrifices as any unprofessional man ever did to the cause of a long and hopeless opposition, and was often treated with unmerited coldness and disrespect by his coadjutors. But as a man his character stood confessedly low. His intemperate habits, and his pecuniary embarrassments, did not merely tend to imprudent conduct, by which himself alone might be the sufferer; they involved his family in the same fate; and they also undermined those principles of honesty which are so seldom found to survive fallen fortunes, and hardly ever can continue the ornament and the stay of ruined circumstances, when the tastes and the propensities engendered in prosperous times survive through the ungenial season of adversity."

Sheridan was indeed most unfortunate. Whilst death was fast gaining on him, the miseries of life were thickening around him; nor did the last corner where he now lay down to die, afford him any asylum from the clamours of his legal pursuers. Writs and executions came in rapid succession, and bailiffs at length got possession of the house. A sheriff's officer arrested the dying man in his bed, and was about to carry him off in his blankets to a spunging house, when he was prevented by an intimation of the responsibility he must incur, if, as was but too probable, his prisoner should expire on the way. In the mean time, the attention and sympathy of the public were awakened to the desolate condition of Sheridan, by an article which appeared in the Morning Post, written, it seems, by a gentleman who, though on no very cordial terms with him, forgot every other feeling in a generous pity for his fate, and in honest indignation against those who had deserted him. But it was now too late. Its effect, indeed, was soon visible in the calls made at Sheridan's door, amongst which the Duke of York and the Duke of Argyll appeared as visiters; but the spirit that these unavailing tributes might once have comforted was fast losing the consciousness of every thing earthly; and, after a succession of shivering fits, he fell into a state of exhaustion, which continued till his death. He expired on Sunday, the 7th of July 1816, in the sixty-fifth year of his age, and was buried on the Saturday following, many royal and noble persons crowding round his insensible clay, whose notice, had it been earlier, might have soothed and comforted his death-bed, and saved his heart from breaking. (J. B—E.)

SHERIDAN, *Dr Thomas*, the intimate friend of Dean Swift, is said by Shiels, in the book known as *Cibber's Lives of the Poets*, to have been born about 1684, in the county of Cavan, where, according to the same authority, his parents lived in no very elevated state. They are described as being unable to afford their son the advantages of a liberal education; but he, being observed to give early indications of genius, attracted the notice of a friend of his family, who sent him to Trinity College, Dublin. He afterwards entered into orders, and set up a school in Dublin, which long maintained a high reputation. From this very popular seminary he is said occasionally to have derived L.1000 a-year. It does not appear that he had any considerable prefer-

[1] It had the singularity of never winking.

ment; but his intimacy with Swift procured for him, in 1725, a living in the south of Ireland, worth about L.150 a-year, which he went to take possession of, and, by an act of inadvertance, destroyed all his future expectations of rising in the church; for, being at Cork on the 1st of August, the anniversary of King George's birthday, he preached a sermon which had for its text, "Sufficient for the day is the evil thereof." On this being known, he was struck out of the list of chaplains to the lord-lieutenant, and henceforward forbidden the Castle. This living Dr Sheridan afterwards changed for that of Dunboyne, which, by the knavery of the farmers, and the power of the gentlemen in the neighbourhood, fell so low as L.80 per annum. He gave it up for the free school of Cavan, where he might have lived well in so cheap a country on a salary of L.80 a-year, besides his pupils; but the air being, as he said, too moist and unwholesome, and being disgusted with some persons who lived there, he sold the school for about L.400; and having soon spent the money, he fell into bad health, and died on the 10th of September 1738, in his fifty-fifth year. One of the volumes of Swift's miscellanies consists almost entirely of letters between him and Sheridan. He published a prose translation of Persius; to which he added the best notes of former editors, together with many judicious ones of his own. This work was printed at London, 1739, in 12mo.

Lord Cork has given the following character of him:—"Dr Sheridan was a schoolmaster, and in many instances perfectly well adapted for that station. He was deeply versed in the Greek and Roman languages, and in their customs and antiquities. He had that kind of good nature which absence of mind, indolence of body, and carelessness of fortune, produce; and although not over strict in his own conduct, yet he took care of the morality of his scholars, whom he sent to the university remarkably well founded in all kinds of classical learning, and not ill instructed in the social duties of life. He was slovenly, indigent, and cheerful. He knew books much better than men; and he knew the value of money least of all. In this situation, and with this disposition, Swift fastened upon him as upon a prey with which he intended to regale himself whenever his appetite should prompt him." His lordship then mentions the event of the unlucky sermon, and adds, "This ill-starred, good-natured, improvident man returned to Dublin, unhinged from all favour at court, and even banished from the Castle. But still he remained a punster, a quibbler, a fiddler, and a wit. Not a day passed without a rebus, an anagram, or a madrigal."

SHERIDAN. *Thomas*, author of the *General Dictionary of the English Language*, was the son of Dr Sheridan, and the father of Richard Brinsley Sheridan, and was born at Quilca, in Ireland, the residence of Dean Swift, in 1721. He was treated with uniform kindness by the great satirist, who was his godfather, and who showed him what tenderness he could during his life. He received his early education in his father's house, and was subsequently sent to Westminster, till the funds failed, when he was compelled again to retrace his steps. He entered Trinity College, Dublin, where he took his degree. On his father's death, in 1738, he found himself suddenly unprovided for. Having caught up, or having been born with, a grand idea of the extraordinary moral effects to be accomplished by the use of the oratorical art, he resolved to devote his life to its exposition. As the first step in his great vocation, he entered a theatre in Smock Alley, where he personated Richard III., "with the greatest encouragement," in January 1743. Next year he went to London, to reap new laurels at Covent Garden, and in 1745 he was set up as a rival to Garrick, who could brook no competitor. Sheridan found it to be for his interest to return to the Irish metropolis, whose inhabitants had not yet forgotten the enthusiastic orator of a few years ago. Here he became manager of the theatre, and during the ensuing eight years of his superintendence, the metropolitan stage seems to have risen considerably in respectability. At an unlucky hour he attempted to humour the political tastes of the public by playing Miller's *Mahomet.* This took exceedingly well. But where was it to end? Like a tiger that has tasted blood, the fierce mob became restless and wild, and insisted upon its accustomed treat. The manager said gravely that there must be an end to these brawls, when the audience rose, and, in its fury, slashed the scenery with sword-blades, tore up the benches and boxes, and ended by totally despoiling the building. Thus ended Sheridan's first school of oratory. In 1751 appeared his greatest contribution to the art of oratory, for this was the year in which his illustrious son, Richard Brinsley Sheridan, was born. His faith in the omnipotence of this ancient art continued. He published a plan for an academy to educate "youth in every qualification necessary for a gentleman," and in which oratory was to be the beginning, middle, and end of their scholastic accomplishments. The orator gave three separate orations to prove the quality of the future superintendent, and to illustrate the vital force of his great discovery. The audience shrugged their shoulders, and gave the conduct of their institution into other hands.

Sheridan was not to be daunted. In 1759 he was lecturing the English on his favourite hobby. He had published an essay on *British Education: the source of the disorders in Great Britain*, 1755, in which he humbly attempted to show the British public, that the source of all their evils, both public and private, was to be traced to a neglect of the ancient and venerable art of public speaking. The British public seem temporarily to have been taken by it. Sheridan lectured himself into an M.A. at Cambridge, and achieved other wonders equally notable by the fascination of his speech at London and Oxford. In 1760 he again tried Drury Lane, but Garrick still recollected his old affront, and Sheridan had to go about his business. He published *A Course of Lectures on Elocution* in 1762, fraught with the old burden. George III. granted him a pension, on which he might have practised oratory to the great edification of the British people and the no small delight of himself; but some busybody whispered the fact to Samuel Johnson, who blustered out, in his violent way, "What, give him a pension! then I must give up mine." On this coming to Sheridan's ears it wounded him mightily; but he had recourse again to oratory as his panacea. Next he moved northward, to try the effect of his eloquence upon the cool heads of the Scottish metropolis. The northern worthies seem to have been moved by the force of his persuasive tongue. Blair, Ferguson, and Robertson were enrolled as directors of a society for the promotion of public speaking. How long this Irish importation flourished in Edinburgh does not appear. Moving south, he published in 1769 his *Plan of Education for the Young Nobility and Gentry of Great Britain.* Ireland found herself again excluded from the benevolent endeavours of this reforming educationist. He dedicated, in his loftiest manner, this small work to the king, observing at the same time, that "if the design be not executed by myself, it never will be by any other hand." It must have gratified his majesty to find so devoted a subject; but nothing seems to have come out of all this kneeling and prostration at the foot of the throne. He continued to lecture and vend sarcasms against the miserable taste of the age, when America suddenly declared her independence. He then informed his audience that he had come to the resolution of "benefiting the new world with the advantages ungratefully neglected by my own country." Sheridan subsequently performed at the Haymarket and at Covent Garden, up to 1776; and on Garrick's retirement from Drury Lane he was appointed

manager. He held this post for the next three years. He published, on his retirement, his *Dictionary of the English Language*, 2 vols. 1780; and an edition of Swift's works, in 17 vols. 1784, with a *Life of Swift* prefixed, a lumbering work, which had better not have been written. He visited Ireland in 1786, and returned to England, where he died at Margate, on the 14th of August 1788, in his sixty-seventh year. There is ascribed to Sheridan a farce called *Captain O'Blunder*.

SHERIF-ED-DEEN-YEZDI, Moolah Ali, a celebrated Persian historian, of whom hardly anything is known, was born at Yezd, in Persia, during the fifteenth century of our era. He was a doctor of the Moslem law, and lived at Shiraz, where he wrote the work by which he is now known, and on which his reputation is founded. This was the *Zuffer-Nameh*, or book of Victories of the celebrated Timur or Tamerlane. This work, which is greatly too much overloaded with metaphor and ornate expression for the occidental taste, possesses, nevertheless, great merit for the oriental beauty in which it is so lustrously set. "His geography and chronology," says Gibbon, in his *History of the Decline and Fall of the Roman Empire*, vol. xii., "are wonderfully accurate; and he may be trusted for public facts, though he servilely praises the virtue and fortune of his hero." His encomiums on Timour are indeed carried to the most fulsome extent of oriental panegyric; but both gratitude and interest would combine to produce this effect; and the bias thus shown is in some measure useful as enabling us to qualify the equally exaggerated invectives of another biographer of Timour, the Syrian Arabshah. Yezdi's book is a panegyric of Tamerlane, and an eastern panegyric too. This work has been translated into French and Turkish.

SHERIFF. See Scotland.

SHERLOCK, William, a learned English divine, was born at Southwark in 1641, and educated at Eton school, where he distinguished himself by the vigour of his genius and his application to study. From this he was removed to Cambridge, where he took his degrees. In 1669 he became rector of the parish of St George, Botolph Lane, in London; and in 1681 was collated to the prebend of St Pancras, in the cathedral of St Paul's. He was likewise chosen master of the Temple, and had the rectory of Therfield, in Herefordshire. After the Revolution he was suspended from his preferment, for refusing the oaths to William and Mary; but at last he took them, and publicly justified what he had done in his publication of the *Allegiance of the Two Sovereign Powers*. His case excited immense sensation. According to Lord Macaulay (*Hist. of Eng.* vol. vi. p. 48, 1858), "the replies to the doctor, the vindications of the doctor, the pasquinades on the doctor, would fill a library." In 1691 he was installed as dean of St Paul's. His *Vindication of the Doctrine of the Trinity* engaged him in a warm controversy with Dr South and others. Bishop Burnet tells us he was "a clear, a polite, and a strong writer; but apt to assume too much to himself, and to treat his adversaries with contempt." He died in 1707. His works are very numerous, among which are —*A Discourse concerning the Knowledge of Jesus Christ*, (against Dr Owen) 1674; *Several pieces against the Papists, the Socinians, and Dissenters; A Practical Discourse on Death*, 16th edition, 1715, which has been more frequently reprinted than any of Sherlock's other works; *A Practical Discourse on Providence*, 1715; *A Practical Discourse on the Future Judgment*, 1699.

Sherlock, *Dr Thomas*, Bishop of London, was the son of the preceding, and was born in 1678. He was educated in Catherine Hall, Cambridge, where he took his degrees, and of which he became master. He was made master of the Temple when very young, on the resignation of his father; and it is remarkable, that this mastership was held by father and son successively for more than seventy years. He was at the head of the opposition against Dr Hoadley, Bishop of Bangor, during which contest he published a great number of pieces. He attacked Collins's *Grounds and Reasons of the Christian Religion*, in a course of six sermons, preached at the Temple Church, which he entitled, *The Use and Intent of Prophecy in the Several Ages of the World*, 1725. In 1728, Dr Sherlock was promoted to the bishopric of Bangor, and was translated to Salisbury in 1734. In 1747 he refused the archbishopric of Canterbury, on account of his ill state of health; but recovering in a good degree, he accepted the see of London the following year. On occasion of the earthquake in 1750, he published an excellent *Pastoral Letter* to the clergy and inhabitants of London and Westminster, of which it is said there were printed in quarto 5000, in octavo 20,000, and in duodecimo about 30,000, besides pirated editions of which not less than 50,000 were supposed to have been sold. Under the weak state of body in which he lay for several years, he revised and published four volumes of *Sermons*, in octavo, which are particularly admired for their ingenuity and elegance. He died in 1762, worth L.150,000. "His learning," says Dr Nicholls, "was very extensive. God had given him a great and an understanding mind, a quick comprehension, and a solid judgment. These advantages of nature he improved by much industry and application. His skill in the civil and canon law was very considerable; to which he had added such a knowledge of the common law of England as few clergymen attain to. This it was that gave him that influence in all causes where the church was concerned, as knowing precisely what it had to claim from its constitutions and canons, and what from the common law of the land." Dr Nicholls then mentions his constant and exemplary piety, his warm and fervent zeal in preaching the duties and maintaining the doctrines of Christianity, and his large and diffusive munificence and charity; particularly by his having given large sums of money to the corporation of clergymen's sons, to several of the hospitals, and to the Society for Propagating the Gospel in Foreign Parts, and also bequeathing to Catherine Hall, in Cambridge, the place of his education, his valuable library of books, and his donations for the founding a librarian's place and a scholarship, to the amount of several thousand pounds. The works of Dr Sherlock were published in 1830, in five vols. 8vo, by the Rev. T. S. Hughes.

SHERWIN, John Keyse, an English engraver of considerable excellence, was born in Sussex about 1751. Being of humble origin, he learned early to handle the instrument of toil. The attention of his master, a Mr Mitford of Petworth, having been drawn to some remarkable drawings which he had executed, he was induced to send one to the Society of Arts, which obtained the silver pallet as a reward. Having subsequently gone to London to learn the art of engraving, he studied under Ashley and Bartolozzi. He won the silver and gold medals at the Royal Academy, and carried off numerous honours from the Society of Arts. Sherwin was appointed engraver to his Majesty and the Prince of Wales in 1785, and continued to drink, brag, and handle the graver, with surprising assiduity. He certainly had genius, but he foolishly supposed that this endowed him also with the right of bullying everybody, both of those above and of those beneath him. His attention was confined mostly to portraits and historical subjects, though he occasionally attempted oil-painting, as in his "Leonidas," but with indifferent success. He died on the 20th September 1790, in very melancholy circumstances, in his thirty-ninth year. (See *Gentleman's Magazine* for 1790–91.)

SHETLAND, or Zetland Islands, a group belonging to Scotland, the most northerly land included in the United

Shetland. Kingdom. Exclusive of the Fair Isle, midway between Orkney and Shetland, and of Foula, which lies 20 miles to the west, the group lies between N. Lat. 59. 52. and 60. 48., W. Long. 0. 45. and 1. 40. These islands are far removed from any other land; Orkney on the S.W. being 50 miles off; the Faroe group, on the N.W., 180 miles; and the coast of Norway, on the E., 210 miles. The whole number of islands and rocks is upwards of 100, but of these only 32 are inhabited. The following is a list of the inhabited islands, beginning from the south:—

	Pop. (1851).		Pop. (1851).
Fair Isle	280	Linga	8
Munsa	10	Mickle Roe	290

The entire area is 5588 square miles, about half of which belongs to the Island of Mainland. This island extends about 60 miles in length, from Sumburgh Head, its southern extremity, to Feideland Point in the north. To the N.E. lies Yell, separated from Mainland by the Sound of Yell; and still farther N.E. is Unst. The other islands, which are much smaller, for the most part fringe the coast of Mainland. These coasts are exceedingly irregular, being indented by extensive land-locked bays, whose mouths are sheltered by islands, and by long narrow arms of the sea called *voes*. So much is this the case, that no part of the island is more than 3 miles from the sea in one direction or another. Yell and Unst are also irregular in outline, but not so much so as the larger island; the former of these is 20 miles long by 6 broad; the latter 11 by 6. The general appearance of Shetland from a distance is not very striking; for the land is all low, though there is a great deal of bold and romantic cliff scenery. The highest point in the islands is Roeness, in the north of Mainland, which only attains the height of 1500 feet above the sea, On approaching Shetland from the south, the first point that appears conspicuously is Fitfiel Head, an abrupt and craggy promontory of Mainland, exceeding in altitude Sumburgh Head further to the east. At the latter point the tides from opposite sides of Shetland meet, causing a tumultuous current, which makes a dark line on the ocean, dying away towards Fair Isle. This is known by the name of the Roust of Sumburgh; and is a good place for the fishery of seethe or coal-fish (*Gadus corbonarius*). About Dunrossness and Quendel, in the south of Mainland, there are some fine corn-lands. Northwards from this, the land consists of bleak hills and heaths, without a tree or even a shrub; and is generally enveloped in damp mists. The coasts are pierced with numerous creeks and inlets, and lined with rugged cliffs and rocks; while the monotony of the scene is occasionally relieved by groups of cottages, with their patches of green corn-land enclosed with stone-dykes. North of the narrow strip of land that forms the southern portion of the island, lies the picturesque bay and village of Scalloway on the west coast, the green vale of Tingwall about the middle of the island, and the town of Lerwick on the Sound of Bressay, which separates Mainland from the island of that name to the east. Beyond Bressay lies the Island of Noss, which communicates with a rock called the Holm of Noss by a wooden trough or cradle, suspended by ropes over a chasm 160 feet deep. North of Lerwick, Mainland extends to a greater breadth, and consists for some distance of extensive boggy meadows, containing several lakes. On the Island of Whalsey, off the east coast of Mainland, an excellent system of farming is carried on; and in the Outskerries, the most easterly of all the islands, there are extensive establishments for deep sea-fishing of ling. The north-western part of Mainland is as wild and grand in its scenery as any other portion of the island. Here are seen the bare red summit of Roeness Hill, several lakes surrounded by heath and rocks, and the surges of the Atlantic for ever dashing on the precipitous cliffs that line the shore. Here is the large bay of St Magnus, at the south side of which lies the Island of Papa Stour, remarkable for its porphyritic rocks and underground caverns. Yell is a dull uninteresting island, but a great fishing station; and Unst is of a bleak precipitous character. The Island of Fetlar, to the east of Yell, contains very fertile valleys. Foula, supposed to be the Ultima Thule of the ancients, consists of five conical hills, rising abruptly out of the sea to the height of 1300 feet. It is occupied by vast flocks of sea-birds in summer, but they all take their flight when winter sets in. The geological character of the islands is very varied. In the southern portion of the Mainland there is a central line of primitive clay-slate, forming the range called the Cliff Hills; on the east of which lies a series of blue and red sandstone, and on the west beds of blue limestone. Further north a great deposit of gneiss occupies the districts of Whiteness, Aithsting, and Delting in the centre of Mainland; the Islands of Burra, Oxna, and Trondray on the west; Whalsay, the Skerries, and Yell, with parts of Fetlar and Unst on the east. Mica slate occurs in the peninsula of Eswick, on the east of Mainland, and at Fadelant Point, in the extreme north. Roseness Hill and the adjoining country are composed of hard red granite, flanked on the south-east by greenstone; and the peninsula in the west forming the parish of Walls, consists of primary quartz rocks. Granite is found in some other parts of Mainland; and the hills of Fetlar and Unst are for the most part composed of serpentine. The mineral riches of the country are not very great; copper veins are found in the Fair Isle and elsewhere; iron, mica, and pyrites in some places; and Unst is especially remarkable for its chromate of iron. The climate is, owing to the insular position of the land, less cold than is common in such a high altitude; but the temperature is liable to very great and sudden changes; and the weather is not unfrequently wet, foggy, and tempestuous. The winter is very dark and gloomy; but, on the other hand, in the summer the sun hardly sinks below the horizon, and bright twilight continues the whole night. Thus from the middle of May to the end of July there is hardly any darkness in Shetland. The soil of the islands is in general very unfavourable for agriculture; and only a very small portion of it is arable. Indeed fishing, not farming, is the chief object of attention both to landlords and tenants; and the climate is so unpropitious that little else but the commonest kinds of barley and oats are raised. In 1857 the islands contained 1026 acres under a rotation of crops; of which 3 were of wheat, 4 of barley, 349 of oats, 91 of bere, 124 of turnips, 64 of potatoes, 371 of grass and hay, &c. The plants and animals of Shetland resemble very much those of Orkney. The country is not so much distinguished by the presence of peculiar species as by its more limited vegetation, and by the absence of many plants common elsewhere. It has been estimated that there are 74 species of plants peculiar to Shetland, 40 common to Shetland and Iceland, 37 to Shetland and Faroe, and 146 to all the three. The most characteristic animals of the islands are the small ponies or shelties. These are very diminutive, but strong and hardy; they run wild on the heaths and pastures of the island, and are exported in great numbers. The cattle, sheep, and hogs of the islands are also small and of peculiar breeds; and the fleeces of the sheep are very much

 esteemed. The islands contained in 1857, 486 horses; 1094 cattle; 6486 sheep; and 57 swine; in all, 8123 live stock. The most important source of wealth to the Shetlanders is the fisheries, in which by far the most of them are employed. There are three different classes of fisheries; the *haaf*, or deep-sea fishing; the herring fishery; and that of the coal-fish. Of these the first is the most important; cod, ling, and tusk being the chief kinds of fish obtained, and furnishing the staple articles of export from Shetland. A large bank of these fish extends from the north of Orkney to the west of Shetland. This fishing is only carried on for two or three months in summer, and it is an occupation accompanied with much danger. The total number of cod and ling taken in the Shetland Isles in 1857 was 1,342,172, being more than a third of the whole number of these fish taken in Scotland. This fishery, as well as that of herring, was at one time almost exclusively in the hands of the Dutch, who sent over annually about 2000 boats to engage in them. Although towards the end of the seventeenth century, and subsequently, this number was greatly reduced, it is not one hundred years since there were only three British vessels engaged in the fisheries here. But from the beginning of the present century, herring fishing has made rapid progress among the Shetlanders; and in 1857 it employed 669 boats, with a tonnage of 1327. The number of fishermen and boys in the same year was 2990; the total number of persons employed 4121; and the number of barrels of herrings cured 17,858. The total value of boats, nets, and lines employed in fishing in Shetland was, for the same year, L.15,822. Very few manufactures are carried on in Shetland, the only one of any importance being hosiery from the fine wool of the sheep. The plaiting of straw was formerly pursued in Lerwick, but this has fallen off. Kelp is also prepared, but not to so great an extent as in the Western Isles. The trade consists in the exportation of fish, hosiery, shelties, &c., in exchange for the various necessaries and luxuries of life which nature has denied to the Shetland Islands. The inhabitants of Shetland are all of Scandinavian origin, and differ entirely from the Highlanders of Scotland. They are small, light, nimble and hardy, lively and versatile, and fond of excitement. They do not speak Gaelic, nor are any of the names of places Celtic; but they have retained many Norse words and idioms, and speak with a quick pronunciation, quite different from that of the Highlanders. The dress of the fishermen is peculiar, consisting of wide, neat skin-boots, reaching to the knee, woollen breeches, a leather surtout, and a worsted cap. The first people whom we know to have inhabited Shetland was a tribe of Saxon rovers, but they were expelled by Theodosius A.D. 368. In the sixth century it is probable that the Scandinavians, from whom the present inhabitants are sprung, had already settled here. Harold Harfager, who first united Norway into one kingdom in 875, reduced to subjection all the northern and western islands, which had been previously held by petty chieftains and pirates. Caithness, Orkney, and Shetland were then made one earldom, and conferred on Siguard, who afterwards considerably extended his dominions. The authority of the earls over Shetland was, however, very slight, for it was not the feudal system, but a totally different form of government that prevailed here. The arable land was held free from any tax or impost, and hence was called *udal*; the pastures, for which a tax was paid, were known by the name of *scattald*. The country was under a civil governor appointed by the king, and was subdivided into lesser districts, each governed by a *foude* or inferior magistrate, from whom there lay an appeal to the grand *foude*, or annual assembly of all the *udal* proprietors. The Earl of Orkney had no right to interfere with the civil affairs of the people; he was only their military protector, under whose standard they had to fight in case of invasion. In 1468 James III. of Scotland received with the Princess Margaret of Denmark a dowry of 60,000 florins, in pledge for which Orkney and Shetland were given; and in 1470 he purchased the whole right to these islands and annexed them to the crown. The various changes that took place in the earldom of Orkney, which included Shetland, after its annexation to the Scottish crown, are narrated in the article ORKNEY. Under the various earls, especially those of the Stuart family, the people were very much oppressed, from the constant attempts to substitute the feudal system for their original *udal* right. The ancient constitution was finally abolished in the reign of Charles II. The islands now form, along with Orkney, a county, which returns one member to the Imperial Parliament, a privilege not possessed by Shetland before the Reform Act of 1832. In ecclesiastical affairs Shetland forms a synod of the Established Church, composed of three presbyteries and twelve parishes. The whole number of places of worship in Orkney and Shetland, according to the census of 1851, was 123, with 39,761 sittings—of the former 41 belonged to the Established Church; 23 to the Free Church; 18 to the Wesleyans; 16 to the Independents; 14 to the United Presbyterians; 9 to the Baptists; and 2 to the Original Seceders. At the same period there were 111 public schools, and 36 private schools in the county. The number of proprietors in Shetland is 574, and the valuation of rent for 1858–9 was L.24,698. Lerwick is the chief town, and it seems to have been erected since the beginning of the seventeenth century. There are many interesting remains of antiquity in the Shetland Islands. Among these are many Pictish towers, especially one in Munsa, which is one of the most perfect Teutonic forts in Europe. The castle of Scalloway is of a much later date, having been erected in 1600; but it is now reduced to a mere shell. In the valley of Tingwall is still to be seen the place where the chief magistrate of Shetland used to hold his court in the open air, at the head of a small loch. The population of Shetland in 1801 was 22,379; in 1811, 22,915; in 1821, 26,145; in 1831, 29,392; in 1841, 30,558; and in 1851, 31,078.

SHIELD, WILLIAM, a very popular English composer of music, was born at Swalwell, in the county of Durham, in 1749. His father, a teacher of singing, taught him the elements of music, and he very early showed considerable talent as a violinist. When nine years old he lost his father, and was apprenticed to a boat-builder at North Shields. His master treated him kindly, and encouraged his musical pursuits. At the end of his apprenticeship he resolved to adopt music as a profession; and having become favourably known as a violinist at Newcastle, attracted the notice of Charles Avison, who gave him instructions in harmony. Having been invited to lead the concerts at Scarborough, he there became acquainted with Borghi the violinist, and Fischer the famous oboeist, who induced him to go to London, and obtained for him an engagement as a violinist in the opera-house orchestra, then led by Giardini. Soon after he was appointed principal viola by Cramer, the new leader at the opera, and held that place for eighteen years. In 1778 he made his first essay as a dramatic composer in *The Flitch of Bacon*, which was very successful. He was next engaged as composer to Covent Garden Theatre, where his compositions became highly popular. In 1791 he revisited Swalwell, and showed much kindness and attention to his mother. While there he made a collection of English *Border Tunes*, some of which he published in his *Rudiments of Thorough Bass*. In the same year he visited France and Italy, and in 1792 returned to England, and composed again for Covent Garden Theatre, but soon after gave up his engagement. In 1800 he published his *Introduction to Harmony*, a second edition of which appeared in 1817. In that year Shield suc-

ceeded Sir William Parsons as Master of the King's Band, with a yearly salary of L.250. He died of dropsy on 25th January 1829, leaving a widow but no children, and was buried in the cloisters of Westminster Abbey. Shield's great popularity arose from the simplicity and appropriateness of his melodies, whether in ballad or opera-song. Always vocal and pleasing, his melodies at once caught the public ear, and became popular. Among his sea-songs, some are peculiarly excellent, such as "The Arethusa," and "For England when with Favouring Gale;" in his operas of "The Lock and Key," and "Hartford Bridge." He was not a trained and profound harmonist, as his instrumental music and accompaniments prove. He was strong in melody, but feeble in harmony. He composed thirty-four operatic works, and a great many detached songs, besides six canzonets, and a cento of ballads, rounds, &c. His instrumental compositions consist of a concerto; duets for two violins; trios for two violins and a bass. In these trios, he introduced an example of that jerking and unmanageable rhythm, $\frac{5}{4}$. (G. F. G.)

SHIELD. See HERALDRY.

SHIELDS, NORTH and SOUTH, two towns of England, on opposite sides of the mouth of the Tyne, situated 8 miles below Newcastle, 16 miles N.N.E. of Durham, and 176 N.N.W. of London.

North Shields is a market-town in Northumberland, forming, along with the adjacent village of Tynemouth, a municipal and parliamentary borough. It extends for about a mile along the river, and consists of an older and a more recent portion; the former containing narrow alleys and lanes, and the latter having many good houses, broad streets, and spacious squares. There are several good public buildings. Among these are the parish church of Tynemouth, which stands at the east end of North Shields, a handsome chapel of ease in the town, places of worship belonging to the English Presbyterian Church, Wesleyan and New Connexion Methodists, Baptists, Independents, Quakers, and Roman Catholics. The educational establishments are many and various, including national, British, and infant schools. There is also a subscription library, mechanics' institute, theatre, assembly rooms, and baths. Manufactures are extensively carried on at North Shields, but they are chiefly of those articles that are connected with navigation. There are here ship-building yards, rope-works, manufactories of sail-cloth, iron-foundries, forges for anchors and chain-cables, and steam-engine manufactories; besides salt-pans, breweries, brick and tile works, a large pottery, &c. In the vicinity there are numerous collieries, furnishing the chief article of trade to the town. North Shields is connected by railway with Newcastle and Tynemouth, and by a steam-boat ferry with South Shields. A county court is held in the town, and there are weekly markets and annual fairs. The town sprung up in the time of Edward I., under the protection of the Prior of Tynemouth; but the jealousy of the people of Newcastle put a stop to its progress for a long time. Oliver Cromwell passed an act for the formation of quays and a market here; but many restrictions were imposed upon the trade till the end of the seventeenth century, when they were removed, and the prosperity of the place thus greatly increased. Pop. 8882.

South Shields is a market-town, parliamentary and municipal borough, in the county of Durham. The older part consists chiefly of a long, narrow, crooked street, extending for about two miles on the low ground by the river's side; but on the hills behind there stand many well-built houses of more modern origin. Near the centre of the town is a large market-place, in which stands the neat town-hall, also used as an exchange and news-room. Below this building is the market-house. The parish church is ancient, but has been so much repaired and altered, that little of its original fabric except the tower can be traced. There are two other established churches, and also places of worship belonging to the English Presbyterian Church; the United Presbyterians; Wesleyan, Primitive, and New Connexion Methodists; Independents; and Baptists; several of which sects have more than one place of worship. To most of them Sunday schools are attached; and South Shields possesses also national and charity schools, as well as numerous benevolent institutions. Among the latter is a set of comfortable houses for superannuated master-mariners. Besides the public buildings already mentioned, the town contains a custom-house, theatre, public baths, mechanics' institute, and subscription library. None of the buildings, however, are by any means imposing. The manufactures and trade of the place constitute its chief importance. Like North Shields, it manufactures chiefly those articles that are used for maritime purposes. There are large docks for ship-building and repairing, also rope-works, breweries, manufactories of soda and alum, a pottery, and extensive glass-works. Formerly the town was chiefly known for its many salt-pans, of which there were at one time nearly 150; but this department of manufacture is hardly at all pursued at present. In the immediate neighbourhood there are some coal-pits. The refuse from these, as well as from the glass-works and salt-pans, has formed numerous hillocks, some of which have been built upon. The borough is governed by a mayor, eight aldermen, and twenty-four councillors; and it returns a member to the House of Commons. Markets are held every Saturday, and fairs twice a-year. It appears from an ancient inscription and remains found here, that there was a Roman station on the site of South Shields. The present town, however, cannot be traced so far back, but seems to owe its origin to the fishermen of the Tyne, who lived in *sheels*, or sheds, along the water's edge. Hence the name of the place. From the fifteenth to the seventeenth century, it was chiefly remarkable for its salt-pans; but the modern prosperity of South Shields is coeval with the extension of the coal trade. The population of the parliamentary borough in 1851 was 28,974.

The port of Shields, including both the towns, is formed by the river between them, which is here about two-thirds as broad as the Thames below London Bridge. Along both sides there are spacious quays, which, like those in the port of London, are lined with several tiers of vessels. The entrance to the harbour is somewhat difficult, as there is a bar with only 7 feet of water. There are two light-houses in North Shields, one 123 and the other 77 feet high, which lead to the entrance of the port. Inside the bar the depth increases to 24 feet; and the harbour is large enough to hold 2000 merchant-vessels, and admits those of 300 tons close up to the quays. The number of sailing vessels registered at the port, December 31, 1857, was 967; tonnage, 262,659: of steam-vessels, the number was 130; tonnage, 2936. In the year ending at that date, there entered 1861 sailing vessels, tonnage 300,538; and 10 steamers, tonnage 1321—in all, 1871 vessels, tonnage 301,859: and there cleared 2187 sailing vessels, tonnage 274,274; and 14 steamers, tonnage 556—in all, 2201 vessels, tonnage 274,830. The chief trade of the port consists in the export of coals to London, and other places on the east coast of England and Scotland. Many of the vessels belonging to Shields are engaged in the whale-fishery of Greenland and Davis Straits.

SHIFFNAL, a market-town of England, Shropshire, 17 miles E.S.E. of Shrewsbury, and 135 N.W. by W. of London. It contains no remarkable building except the large and handsome parish church, which is in the form of a cross, with a fine carved roof and some Norman remains. The other places of worship belong to the Baptists and Independents. There are also national schools and a

blue-coat school. Many of the inhabitants are employed in the mines and coal-pits in the vicinity, and in a paper manufactory. Pop. of the parish, 5617.

SHIKARPOOR, a town of British India, the most commercial and probably the most populous in Sinde, though not the capital of that province. stands in a low flat region, 20 miles W. of the Indus; N. Lat. 28., E. Long. 68. 39. Its appearance is not attractive, either viewed from a distance or on a nearer approach; the wall that once encircled it is in ruins, the streets are narrow, and a great part of the area consists of open spaces. There are no public buildings of any note; the most conspicuous edifices being the massive gloomy houses of the rich Hindu merchants. Near the centre stands the bazaar, 800 yards long, and covered with a thatched roof, which renders the atmosphere beneath very close and oppressive. The trade of the place is very great, as it stands on one of the great routes from Sinde, through the Bolan Pass to Afghanistan and Khorasan; on another leading northwards to the Derajat; and on a third leading to the port of Kurrachee. It is thus a transit trade that is chiefly carried on here, including large banking and other monetary transactions. There are many great capitalists in the town. The population is estimated at 30,000, of whom about 20,000 are Hindus, and the rest Mohammedans.

SHILLING. See Coinage.

SHILOH (שִׁילֹה), is a term famous among interpreters and commentators upon Scripture. It is found (Gen. xlix. 10) to denote the Messiah. The patriarch Jacob foretells His coming in these words:—"The sceptre shall not depart from Judah, nor a lawgiver from between his feet, until Shiloh come; and unto him shall the gathering of the people be." All Christian commentators agree that Shiloh ought to be understood of the Messiah, or Jesus Christ; but all are not agreed about its literal and grammatical signification. St Jerome, who translates it by *Qui mittendus est*, manifestly reads *Shiloach*, "sent," instead of *Shiloh*. The Septuagint have it, "Until the coming of him to whom it is reserved;" or, "till we see arrive that which is reserved for him." It must be owned that the signification of the Hebrew word Shiloh is not well known. Some translate, "the sceptre shall not depart from Judah, till he comes to whom it belongs. Others render it, "Till the coming of the peace-maker," or "the pacific;" or "of prosperity," *prosperatus est*. Others, again, "till the birth of him who shall be born of a woman that shall conceive without the knowledge of a man;" otherwise, "the sceptre shall not depart from Judah till its end, its ruin; till the downfall of the kingdom of the Jews." Some rabbin have taken the name Siloh or Shiloh, as if it signified the city of this name in Palestine: "The sceptre shall not be taken away from Judah till it comes to Shiloh; till it shall be taken from him to be given to Saul at Shiloh." But in what part of Scripture is it said that Saul was acknowledged as king or consecrated at Shiloh? A more modern author derives Shiloh from a word which signifies to be weary, or to suffer; "till his labours, his sufferings, his passion, shall happen."

But it is sufficient to show that the ancient Jews are in this matter agreed with the Christians. They acknowledge that this word stands for the Messiah, the King. It is thus that the paraphrasts Onkelos and Jonathan, that the ancient Hebrew commentaries upon Genesis, and that the Talmudists themselves, explain it. The curious reader may consult Jacobi's *Alting Schilo*, iii. 8, for further information respecting this matter.

SHING-KING, or Leao-Tong, a maritime province of the Chinese empire, lying to the north of the Yellow Sea, shut off from China proper on the S.W. by the Great Wall, and by another fortification from Mongolia, Manchoorie, and Corea on the N. and E. Area, 25,000 square miles. It is mountainous, and watered by the Leao, which flows southwards into the Gulf of Leao-Tong. The east side of this gulf is formed by a long peninsula called the Regent's Sword. The climate is mild and salubrious; and the soil produces wheat, barley, pulse, millet, and buckwheat. The mountains are covered with fine timber. Moukden is the capital of the province. Pop. 942,043.

SHIP-BUILDING.

To a people whose power is essentially maritime it is not necessary to use any arguments in proof of the importance of ship-building. Without pausing to dwell on the various struggles by which England has maintained her position amongst nations, it must be seen by all who study her history, that it has been by keeping invaders from her shores, by means of her wooden bulwarks, that she has withstood the repeated attacks of the powerful nations of the continent. And whilst the navy must be looked upon as the proper means of defence to this sea-girt land, who can visit the docks of London, Liverpool, the Clyde, or any of her other commercial ports, and not feel that her very heart's strength lies in those forests of masts which bring wealth to her merchants and manufacturers, and the means of employment to her artizans, forming, at the same time, a nursery and a reserve of seamen, who will be ready in the hour of need to vindicate her claim to pre-eminence on the ocean? Who, it may also be asked, can look upon the changes effected by her instrumentality in all quarters of the globe, and not own that her winged messengers have, under God's blessing, been the means of spreading civilization and truth through a large portion of the world?

The love of a sailor's life, common to all ranks amongst her sons, owes perhaps its origin to their Norman forefathers; but, however begotten, and however fostered, England owes much to it, and to the spirit of adventure which it has engendered amongst them. Individual enterprise has led to national achievements, till the name and power of Great Britain have been so extended that the sun never sets upon her possessions.

In an age when science is lending its mighty aid to every peaceful and warlike art, when mighty armies may be suddenly concentrated by railroads, and a nation's fate may hang on the electric wire, England must not trust in the multitude alone of her ships. Every fresh struggle for wealth or power proves that it is the amount of mind and intellect put forth in that struggle, and the amount of energy, and of means used to effect the end desired, which, humanly speaking, ensure success; and, as knowledge is always increasing, nations or individuals must not rest upon what has been done, if they desire to keep pace with the world in its eager rush of advancement and improvement. With regard to ship-building, not only must ingenuity and skill be brought to bear to assist the artisan in the practical construction of the fabric, but men of science must lend their aid, and use their powers of investigation, to assist in designing a complete whole, adapted to meet the ever-increasing competition for mastership on that element on which not only the welfare of England but of the whole world seems to hang.

The limits of a treatise of this nature are such that a very general view only of the many branches of inquiry in-

History. volved in this important subject can be given. It could not, however, be considered complete without a short outline of the rise and progress of the art, or without some reference to the authors from whose works further information may be obtained. It is always interesting and instructive in every art to trace the various stages it has gone through before arriving at its existing state. The retrospect of the art of ship-building shows that there has been no standing still in its course without corresponding injury to the prosperity and power of the nation which has neglected it, and that there must be no relaxation of exertion to meet the demands of a commercial and warlike people.

RISE AND PROGRESS OF NAVAL ARCHITECTURE.

In tracing the progress of naval architecture among the nations of antiquity, in order to connect it with its advance in more modern times, the chronological divisions adopted by that indefatigable investigator, Charnock, in his valuable *History of Marine Architecture*, present a very succinct idea of the probable rise, progress, decline, and revival of the art, and therefore offer a valuable guide for investigation. It would not be consistent with the purpose of this article to enter into the detail that would be necessary to ascertain the state of naval architecture during the periods embraced in each of the sections he has assigned to this subject. Some few facts only will be collected from various authors in illustration of the probable size and nature of the shipping of the ancient world, with an outline of what little is known of the rude vessels which, during the darkness of the middle ages, bore the marauders of the northern nations on their predatory excursions. Charnock divides maritime history into seven sections. The first comprehends the time previous to the foundation of Rome, until which he considers that all history is founded on surmise. The second section comprises a period somewhat less obscure, in which the collateral testimony of various authors may be examined and compared; and therefore there certainly appears less difficulty in ascertaining facts. It extends from the foundation of Rome to the destruction of her rival, Carthage. The termination of the third is at the conversion of the Republic into an empire. The death of Charlemagne ends the fourth epoch. The fifth extends from this period to the discovery of the mariner's compass. The sixth ends with the discovery of cannon, and with their adaptation to naval warfare commences the seventh epoch.

The Ark. The first vessel of which we have any description is the ark as built by Noah under the directions of the Almighty. Its proportions possess some interest, because, though not intended for a voyage, it may be inferred that it was constructed to float with as little motion as possible, considering that it "went upon the face of the waters" for about five months. It was no doubt exposed to the action of the winds and waves during that period, for before it rested "a wind was made to pass on the earth, and the waters asswaged." Assuming a cubit to be about 18 inches of our measure, its length was about 450 feet, its breadth about 75 feet, and its depth about 45 feet, with an arch or round-up of the upper deck of about 18 inches. Its draught of water must have varied greatly during the period of its occupation, as twelve months' provisions must have formed a very large proportion of the original weight, and these must have been gradually consumed. Its length is thus seen to have been six times its breadth, and it is perhaps curious that ship-builders should not sooner have given this, or a greater proportion of length to their vessels; seeing that these were intended for locomotion, with as much speed as possible, and consequently that an increase of length must have been proportionally advantageous to them, by giving them a finer form. The remembrance of this huge vessel, or floating house, would remain long on the minds of Noah's posterity; but it was not likely to influence them in the construction of petty floating vessels, to meet any of their limited requirements. Wickerwork frames of rushes, or reeds, or of the rind of the papyrus, smeared with mud or pitch, similar to the ark in which Moses was exposed, appear to have been at a very early age brought into use, and basketwork, covered with skin, has continued in constant use among many nations, even up to the present time. They are still in use in some parts of this and other countries under the name of coracles. Canoes, formed out of the trunk of a tree, require tools or implements for their construction, and were, therefore, no doubt of later introduction.

Vessels of Ancient Egypt. As early authentic records on the subject of ship-building, the paintings and sculptures of Upper and Lower Egypt may be referred to. These show regularly formed boats, constructed of sawn planks of timber, propelled by numerous rowers, and also by sails. Some are represented as formed with inclined planes, forward and aft in the same manner as the barges on the Thames, and in this respect are more correct in theory and in reality as to ease of propulsion than many canal-boats of the present day, constructed of a wedge-like form. The Hebrews in the time of Solomon must have possessed vessels of considerable size, as mention is made, in the sacred writings of that date, of "stately ships" and of voyages made to bring trees of considerable size to be used in the building of the temple. In addition to the trade in the Mediterranean from Joppa and Tarshish, it is also recorded that Solomon despatched a navy of ships from the Red Sea to fetch gold from Ophir, the position of which, though disputed, was probably on the east coast of Africa.

Phœnician shipping. The Phœnicians were connected with the Hebrews in their maritime expeditions, and this people appear to have been the most enterprizing in navigation of all the nations of antiquity. There can be no doubt from the accounts given by that most pains-taking and careful historian, Herodotus, that an expedition fitted out by this people sailed round the Cape of Good Hope. They started from the Red Sea, and after passing Ophir, if situated, as previously supposed, on the east coast of Africa, and to which they were in the habit of trading, they rounded the Cape, and keeping by the shore they entered the Mediterranean through the pillars of Hercules, or Straits of Gibraltar, and arrived in Egypt in the third year of their expedition. Vessels capable of performing such a voyage must have been of considerable size.

Grecian shipping. The Phœnicians were also engaged, in concert with other nations, in wars with the Greeks; and it was from them that the latter nation learned in their wars what they knew of ships and of navigation. Amongst the Grecian states, the Corinthians appear to have most distinguished themselves by improving the forms of the galleys, and increasing their size. The people of Tuscany and the Carthaginians also became important maritime powers about this time.

Roman shipping. The Romans in the earlier stage of their history paid little attention to navigation, until it was forced upon them by the necessity of competing with their great rivals the Carthagenians. The galleys of this period ranged from a single bark up to the quinquireme of five banks of oars. The oars in these large galleys being arranged in sets or *banks*, the number of these could be increased to any extent by giving additional length to the galley. The trireme, or three-banked galley, appears to have been generally open in the middle where the rowers sat, with decks or platforms at both ends for the soldiers; but this was not always the case, as in the representation of a trireme found at Pompeii, it is decked over for its whole length, and with a house or inclosed space at the stern. The galleys of greater size than the triremes appear to have been always decked-vessels, and the upper or fourth and fifth oars of

each bank were probably pulled from the deck, in the same manner as the long oars of the present day, called sweeps, while the three lower oars were pulled through port-holes by men seated below the deck.

The chief information on the vessels of this period is gathered from the accounts of naval expeditions and engagements as recorded in the histories of the Peloponnesian war by Thucidydes; the wars of Alexander the Great, especially the siege of Tyre, by Curtius and Arrian; the battle between Demetrius and Ptolemy, by Diodorus Siculus; the first Punic war, by Polybius, in which a very minute account is given of the engagement between the Romans and the Carthaginians; and of the battle of Actium, by Dionysius Cassius. Cæsar, in his *Commentaries*, also gives an account of the vessels used in the invasion of Britain, which seem to have been of greater draught of water than common at that period, as he considers it worthy of recording, that the men on disembarking were breast-high in the water, and that at last the galleys were ordered in between these larger vessels and the shore, to protect the disembarkation.

Classes of Roman shipping. The Roman ships were divided into three classes: the *naves longæ*, or ships of war; the *naves onerariæ*, or ships of burthen; and the *naves liburnæ*, which were ships built expressly for great velocity, and may be supposed to have been used as despatch-boats, and for making passages with important personages. There is repeated evidence to prove that these vessels were invariably built of pine, cedar, or other light woods, excepting about the bows, which were of oak, strongly clamped and strengthened with iron or brass, in order to withstand the shock of opposing vessels; the tactics being comprised in the attempt to sink or damage the enemy's vessel, by violently propelling this armed bow against the weaker broadside of the enemy, or else endeavouring to break and cripple the oars. **Oak first used in ship-building.** Oak was first applied to ship-building by the Veneti, on the testimony of Cæsar in his treatise *De Bello Gallico*, lib. iii. cap. 13. **Copper.** Copper or brass was introduced for fastenings, in consequence of the quick corrosion of the iron, about the time of Nero. This is stated on the authority of Vegetius, and also of Athenæus; and Pliny mentions that flax was used **Caulking.** for the purpose of caulking the seams of the plank.

Exhumation of a Roman vessel. The following quotation is from Locke's History of Navigation:—"Sheathing of ships is a thing in appearance so absolutely new, that scarce any will doubt to assert it altogether a modern invention; yet how vain this notion is, will soon appear. Leo Baptisti Alberti, in his book of *Architecture* (lib. v. cap. 12), has these words: But Trajan's ship weighed out of the lake of Riccia at this time, while I was compiling this work, where it had lain, sunk and neglected, for above 1300 years; I observed that the pine and cypress of it had lasted most remarkably. On the outside it was built with double planks, daubed over with Greek pitch, caulked with linen rags; and over all a sheet of lead fastened on with little copper nails. Raphael Volaterranus, in his *Geography*, says this ship was weighed by the order of Cardinal Prospero Colonna. Here we have caulking and sheathing together above 1600 years ago; for I suppose no man can doubt that the sheet of lead nailed over the outside with copper nails was sheathing, and that in great perfection, the copper nails being used rather than iron, which, when once rusted in the water, with the working of the ship, soon lose their hold and drop out."

During the dark ages which followed the downfall of Rome, little progress was made in navigation, and but little is known of the vessels in which the northern hordes made their predatory and conquering excursions.

Royal Society of Northern Antiquarians. The investigations of the Royal Society of Northern Antiquarians at Copenhagen have thrown considerable light on the subject of this early navigation, and of the discoveries of the Scandinavians in the west; and it cannot be supposed that it was in coracles that frequent voyages were made to Newfoundland, and colonies established there, which it appears proved were in existence as early as the tenth century. But to recur to the description given by Cæsar of the ships of the Gaulish Veneti. **Gaulish Veneti.** "Their bottoms were somewhat flatter than ours, their prows were very high and erect, as likewise their sterns, to bear the hugeness of the billows and the violence of the tempests. The body of the vessel was entirely of oak. The benches of the rowers were made of strong beams about a foot in breadth, and fastened with iron nails an inch thick. Instead of cables, they secured their anchors with chains of iron; and made use of skins and a sort of thin pliant leather, by way of sails, probably because they imagined that canvas sails were not so proper to bear the violence of tempests, the rage and fury of the winds, and to govern ships of that bulk and burthen. . . . . . Neither could our ships injure them with their beaks, so great was their strength and firmness, nor could we easily throw our darts, because of their height above us, which also was the reason that we found it extremely difficult to grapple the enemy and bring him to close fight." And again, speaking of the manner in which these ships were eventually taken possession of: "They," the Romans, "had provided themselves with long poles, armed with long scythes; with these they laid hold of the enemies' tackle, and drawing off the galley by the extreme force of oars, cut asunder the ropes that fastened the sailyards to the masts; these giving way, the sailyards came down, insomuch that, as all the hopes and expectations of the Gauls depended entirely on their sails and rigging, by depriving them of this resource, we at the same time rendered their vessels wholly unserviceable."

The account proceeds to state, that many attempted to escape from this unforeseen means of aggression; but that the wind falling, and a perfect calm coming on, they were obliged to remain inactive on the water, and were taken possession of, one after the other, by the simultaneous attack of several Roman galleys. It would appear from this that they were vessels only intended for sailing, and that, since oars were used, from the mention made of seats for the rowers, they could have been as very partial accessories to the sails, or probably even only for steering. Another fact is mentioned by Cæsar, that the Veneti sailed from their port to meet the Roman fleet, and several of the vessels escaped to their port from the fleet. This, though not conclusive of the fact of sailing on a wind, is worthy of notice.

Hengist and Horsa. It is probable that it was ships such as these which brought Hengist and Horsa to England about the middle of the fifth century, since it is recorded that their force, which consisted of 1500 men, found accommodation in only three vessels. It is hardly to be imagined that the coracles, or skin-boats of the northern nations, were ever of sufficient dimensions to accommodate a force of 500 men, with arms and means of active aggression.

Rise of Venice. The earlier irruptions of the northern barbarians into Italy had desolated the Roman province of Venetia, and driven a remnant of its inhabitants to the refuge afforded by the small marshy islands at the extremity of the Adriatic. There they are described by Cassiodorus, who assimilates them to water-fowl, as subsisting on fish, and steeped in poverty, their only manufacture and their only commerce being salt. From such humble beginnings arose the state destined to connect the old world with the new, and to lead the van of modern commercial and maritime enterprise. The mercantile prosperity of Venice diffused its influence throughout the shores of the Mediterranean, which thus became once again the nursery of civilization. For many centuries Venice was the great school of the arts connected with navigation, and her shipwrights and seamen were long the most instructed in Europe. While the north-

History.

ern seas were navigated by the Scandinavian sea-kings, in their rude and frail boats, in quest of plunder or of a home, ships floated on the waters of the Mediterranean bearing the banner of St Mark, which, it is said, were, even as early as the tenth century, of the burthen of 1200 up to 2000 tons. The vessels, however, generally adopted by the Mediterranean states were either copies or modifications of the ancient galley.

Mediterranean galley.

It is a fact worth notice, that while the continuation of the use of this species of vessel in the comparatively tranquil waters of the Mediterranean fostered the arts of commerce and navigation, its introduction into the northern seas, to which it was ill adapted, appears to have checked, in a most remarkable degree, the maritime enterprise which had hitherto so characterized the population of their coasts. It is even probable that the barrier thus opposed to commerce entailed on the states of Northern and Western Europe centuries of comparative barbarism.

Alfred.

Alfred was the first ruler of England who clearly understood that the policy of Britain was rather to prevent than to resist invasion; and the bygone history of his country told him plainly that its military strength was not only insufficient to awe invaders from its shores, but that all the military resources at his command were inadequate to preserve the liberties of his people. He therefore turned the energies of his mighty mind to the task of creating a naval force, which should be more powerful than that of his untiring persecutors the Danes. In this he succeeded; and at length, under the protection of the fleets which his genius had created, he was enabled to establish that framework of internal policy and government, from the wisdom of which England has even to this day benefited. It is historically certain that Alfred himself superintended the formation of his fleet, and that he gave the design of vessels to be superior to those of the Danes.

His ships.

These vessels were galleys, generally rowed with forty oars, some even with sixty, on each side; and they were twice as long, deeper, nimbler, and less "wavy" or rolling, than the ships of the Danes. The information on this subject is obtained by Selden from a Saxon chronicle of the time of Alfred, which is in the Cottonian Library.

Reasons for their introduction.

It should be remembered, that when Alfred thus introduced the Mediterranean galley into these northern seas, his object was not so much to form a vessel adapted for the purpose of navigating those seas, as to obtain one which would afford space for a large force of fighting men. For this the galley was admirably qualified; and indeed it maintained its place as the appropriate ship for the purposes of war until the invention of cannon rendered other arrangements necessary.

Their success.

The immunity which it insured from the attacks of the Danish marauders caused its general adoption along the coasts hitherto open to their incursions, on all of which it thus superseded the sailing vessels that have been already described; and voyages which, until its introduction, were boldly and successfully achieved, became of rare occurrence and of hazardous issue during the subsequent ages, until the galleys once again gave place to sailing vessels. It also gradually checked the enterprise of the Northmen, by the curb which it placed upon their successes.

Saxon rule.

It is not proposed to give more than a slight sketch of the naval history of Britain through the line of her Saxon princes; for little data can be found on which to base any speculation even, as to the progress of naval architecture during these ages. The galley of the Mediterranean continued to be used for the defence of the coasts; and the policy of Alfred appears to have been well understood by many of his successors—that England only enjoyed peace from invasion when her fleets were powerful enough to repel it from her shores. It is also to be inferred that the use of sailing vessels was not wholly abandoned; for in the reign of Athelstan, the third in descent from Alfred, as recorded by Hackluyt, it was decreed, that "if a marchant so thrived, that he passed thrise over the wide seas of his owne crafte, he was thenceforth a Thein's right worthie."

Mercantile shipping.

This establishes two rather interesting facts: one is, that at so early a period there were merchants of importance enough to engage in such a traffic; and the other is, that from the richness of the reward held out to successful enterprise, the difficulty of the task assigned must have been estimated as great. It may be assumed that these long voyages were made in ships more adapted for the purpose than galleys; in fact, in the vessels which the galleys had been intended to supersede. But the spirit of maritime enterprise had, as before observed, evidently received a check, since one of the highest rewards in the power of the monarch to bestow was held out to the merchant as an incitement to an adventure, which the vague hope of plunder would alone have been sufficient to induce that merchant's progenitors to attempt and successfully perform. However, it is probable that at no time was the art of navigating vessels, which depended principally, although perhaps not wholly, upon their sails, lost in the northern seas. Gibbon says, that at the early crusades the vessels of the "Northmanni et Gothi" (the Norwegians and Danes) differed from those of the other powers, among all of whom the ships partook of the character of the Mediterranean galley. These northern crusaders are described by him as navigating "*navibus rotundis*—that is to say, ships infinitely shorter in proportion to their length than galleys." This was not later than the beginning of the twelfth century, and therefore not so far removed from the periods in question as to render the inference proposed to be deduced from it erroneous, particularly when referring to times of such slow improvement as the middle ages.

Decline of naval enterprise.

Edgar.

The "mighty" fleets maintained by Edgar afford no information on the subject of this article, excepting that the facts connected with that monarch's annual circumnavigation of his territories prove them to have consisted of row-galleys. They must, however, have formed comparatively a "mighty" fleet; for, from a grant of land made by Edgar to Worcester cathedral, it is found that he assumed to himself the title of "Supreme Lord and Governor of the Ocean lying round about Britain." That they were but of slight construction may be inferred from the low state of the navy so shortly after the death of Edgar as the reign of Ethelred, who, in order to re-establish it, instituted a regular tax for providing and maintaining a navy. It was enacted, according to Selden, that whoever possessed "310 hides of land was charged with the building of one ship or galley; and owners of more or less hides, or part of one hide, were rated proportionally"—the hide being, according to the best authorities, as much ground as a man could turn up with one plough in a year. But this tax appears to have been inadequate to the purpose of providing a sufficient fleet, for all the exertions of Ethelred could not preserve Britain from again being ravaged by the Danes, and, after the short reign of his son Edmund Ironsides, England was ruled by Danish monarchs. From the known talent of Canute, the first of these princes, and from the crowns of Denmark, Norway, and Britain being united in his person, it may be presumed that the naval affairs of England were not suffered to retrograde. There is, indeed, a record of their advance during this second Danish rule. It may also be inferred from the present which was made by Earl Godwin to Hardicanute, the third Danish sovereign, of a galley, sumptuously gilt, and rowed by fourscore men, each of whom wore on his arm a bracelet of gold weighing sixteen ounces; not that the mere gorgeousness of the gift would prove any advance in the art of ship-building, but it may be supposed, from its nature, that naval affairs found favour in the sight of this monarch. Of this there is also other historical evidence, as Hardicanute raised L.11,048,

Ethelred.

Canute.

History.

in the first two years of his reign, for the purpose of building thirty-two ships; and the taxes he levied for the support of his navy were so grievous that, Florentius says, scarcely any man was able to pay them.

Norman conquest.

The marine of England seems to have been maintained on a comparatively powerful footing up to the period of the Norman conquest; and from the naval resources at the command of Harold the Saxon, in comparison with the insignificance of the shipping which brought William and his Normans across the channel, there can be no doubt that had Harold relied upon his naval strength, the conquest of England would never have been achieved; but, by some fatality, his fleet, which had been long stationed off the Isle of Wight, was dispersed, in consequence of a report that William had abandoned his enterprise.

Fleet of William.

The flotilla of William the Conqueror is variously stated; by some at 900, by others at 3000 vessels. Either number proves their insignificance, as the invading force consisted of about 60,000 troops, which would give in the one case about 66 men to each vessel, in the other 20 men only (figs. 1 and 2).

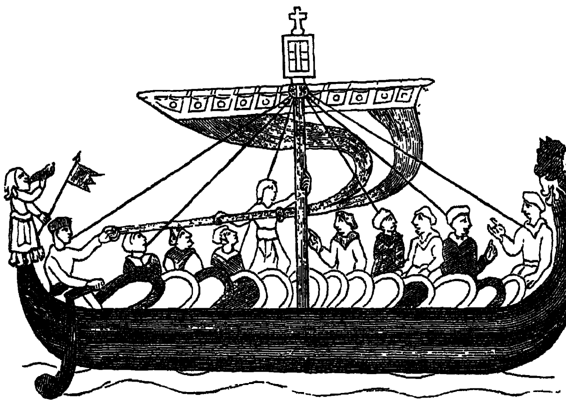

Fig. 1.

The conquest of England being completed, the shores on either side of the narrow seas between England and

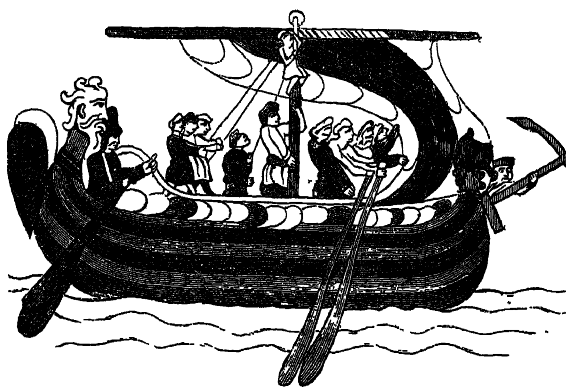

Fig. 2.

Normandy were under the same rule. William, therefore, claimed sovereignty over them, which right was maintained by his successors. There can be no doubt that the constant intercourse between the two portions of the empire, which continued throughout the Norman sway, and indeed for a period of upwards of three centuries, must have done much towards fostering a maritime spirit among the population of England, and accustoming it to consider that fame and fortune were the rewards of nautical adventure.

Probable size of ships.

There is but slight evidence as to the state of naval architecture during the early period subsequent to the Conquest. There are a few facts scattered among the records of these times, from which some vague conclusions as to the probable size and nature of the vessels used may be drawn. When Prince William, son to Henry I., was drowned, by the loss of the vessel in which he was crossing from France to England, it is recorded that 300 souls perished with him. As of this number a large portion, historians say 140, were men of rank, and as there were many ladies, since the prince was accompanied by his sister, the vessel must have been of considerable burthen. A similar event, namely, a shipwreck, that occurred during the reign of Henry II., by which nearly the same number of persons perished, tends to prove that such was about the extent of the accommodation afforded by the shipping of this period. Galleys still continued to be used for the purposes of war; but as commerce began to be extended, it became necessary to recur to the use of sails, and they were therefore gradually recovering their importance, and superseding oars. Indeed, it is difficult to conceive commerce to be profitably engaged in when attended with the immense expense of the crews necessary to propel the larger galleys.

State of trade.

This must have had an important influence in the improvement of navigation and of naval architecture, for the commercial intercourse between the portions of the empire on either side of the channel must have been considerable. There is constant reference in the early chronicles to the great extent of the wine trade, and of the commerce in wool and woollen cloths.

The introduction of vessels propelled by sails for the purposes of commerce would necessarily cause a change in the constitution of the fleets assembled for the services of war; and this will be found to have been the case.

Richard Cœur de Lion.

The expedition of Richard Cœur de Lion, in 1190, to join the crusade to the Holy Land, consisted of nine ships, which are described as being of extraordinary size, 150 others of inferior dimensions, and only 38 galleys. After the reduction of Cyprus, and the addition of the vessels captured there, with others which he had hired at Marseilles and in Sicily, his armament consisted of 254 "tall shippes, and about three score galliots." The increase was, therefore, almost wholly in the ships. This, together with the recorded fact, that he captured a Saracenic vessel of such size as to be capable of containing 1500 Saracens, and a large quantity of military stores, destined for the relief of Achon, tends to prove that the progress of naval architecture, under the influence of the commercial powers of the Mediterranean, had been more rapid than in these northern seas, where the commerce was much more confined in its nature, and the nations bordering on which were in constant warfare with each other.

Sovereignty of the seas.

The Norman monarchs appear to have been very tenacious of their claim to the sovereignty of the narrow seas; and not only their claim, but their power to maintain their right, is admitted by the French historians. The Père Daniel sanctions the claim of Henry II. to this sovereignty.

John.

In the reign of John the fleets of England were of such importance that the claim was extended; for it was then enacted, that if the masters of foreign ships should refuse to strike their colours, and thus pay homage to the English flag, such ships should be considered as lawful prizes. This monarch most carefully fostered the naval power of England; and it is in the records of the thirteenth year of this reign that mention is first made of any public naval establishment.

Early origin of Portsmouth dockyard.

There is in the close rolls, published by the Record Commission, an order, which is dated the 29th of May 1212, from the king to the sheriff of the county of Southampton, in which he is directed without delay to cause the king's docks at Portsmouth to be enclosed by a good and strong wall, in order to protect the king's galleys and ship's; and also to build storehouses against this wall, for the preservation of the fittings and equipment of the said vessels; all of which works are to be performed under the direction of William, archdeacon of Taunton, and the

History.

greatest diligence is to be used, in order that the whole may be completed during the summer.

Edward I.

The naval power of England appears to have continued sufficient to maintain the sovereignty assumed by John. For the occurrence of predatory excursions by some Genoese, during the reign of Edward I., caused all the nations of Europe, bordering on the sea, to appeal to the kings of England, whom they acknowledged to be in peaceable possession of the "Sovereign Lordship and Dominion of the Seas of England, and Islands of the same;" which proves that their claim was generally acknowledged. This document, Evelyn says, was still extant in his time, in the archives of the Tower. The right to the absolute sovereignty of the seas was maintained up to the reign of James I. Queen Elizabeth insisted on and maintained her power to refuse or grant passage through the narrow seas, according to her pleasure. In 1634 Charles I. asserted his right to their sovereignty; and in 1654 the Dutch were compelled, after a severe struggle, to submit to it, and consent to "strike their flags and lower their top-sails on meeting any ship of the English navy on the British seas;" which homage the commanders of English men-of-war were instructed to exact from all foreign vessels until so lately as the close of the last war, when it was judiciously abandoned, for the following reasons, as given by Sir John Barrow. In his *Life of Howe*, with reference to Trafalgar, he says, "That battle, moreover, having so completely humbled the naval powers of France and Spain, suggested to the consideration of the Board of Admiralty, with the approbation of the government, the omission of that arbitrary and offensive article which required naval officers to demand the striking of the flag and lowering of the top-sail from every foreign ship they might fall in with. That invidious assumption of a right, though submitted to generally by foreigners for some centuries, could not probably have been maintained much longer, except at the cannon's mouth; and it was considered, therefore, that the proper time had come when it might, both morally and politically, be spontaneously abandoned."

It is generally supposed that ships intended only for sailing were first built by the Genoese, and that not until the beginning of the fourteenth century. It is perhaps more probable, that in the Mediterranean they date from an earlier period than this; and that although the general adoption of the galley in Western Europe had much checked the art of navigation by means of sails, it had never been wholly lost, but that sailing vessels, though probably very few in number, and imperfect in rig, had been constantly in use. To judge from the few hints handed down to us by history, they were probably luggers, and were adopted for mercantile purposes along the coast of the Channel and the Bay of Biscay. In the north of Europe sails had never been discontinued, although the more warlike galleys of England and France had gradually prevented the incursions of the northern nations into these more southern seas. The beginning of the fourteenth century is, however, decidedly an epoch in the histories both of navigation and of naval architecture, and from it may be dated the progress of navigation by means of sails. It is generally supposed that the "large ships" mentioned in the enumeration of the fleets of this period, were ships built only for sailing, and intended for those long voyages which the invention of the compass by Flavio Gioio, a Neapolitan, about the year 1300, had rendered of comparatively easy performance.

Mariner's compass.

It has been surmised that the compass was brought to Europe from the East about forty years previous to this date, by Paulus Venetus. It is certain that the Portuguese found the knowledge of the magnetic needle generally and long diffused among the eastern navies. Evelyn says, that "it was, near eighty years after its discovery, unknown in Britain." This is not improbable, for there does not remain much record of maritime affairs in the interval between the reigns of John and Edward III. This monarch's reign was, after a most severe struggle with France for supremacy on the seas, the era of a series of naval triumphs, and both navigation and naval architecture made most decided advances.

Edward III.

Naval battle.

In an engagement which took place in 1340, the French force amounted to 400 vessels, of which 120 were "large ships," these being principally Genoese mercenaries. Edward III. commanded the English fleet in person, which consisted of but 260 sail. The French are variously reported to have lost 20,000 and 30,000 men, and 200 vessels are said to have been captured. The loss to the English was only 4000 men. Two facts are elicited by the accounts of this engagement; one is, that there is no mention of galleys as forming any part of the fleets; the other is, that in the James of Dieppe, which was captured by the Earl of Huntingdon, 400 persons were found slain; consequently the size of the vessel must have been very considerable.

Royal fleet.

In 1344 Edward summoned commissioners from all the ports, to meet in the metropolis, provided with the state of their "navies." The roll of this fleet is inserted in the first volume of Hackluyt, from a copy in the Cottonian Library. The total numbers were 710 ships, and 14,151 mariners; and there were 38 foreign ships, with 815 mariners. From this roll it will be seen that galleys had ceased to be used by England, either in her wars or in her commerce, as neither among the king's ships nor among those furnished by merchants is there any mention of them. This fleet was that engaged in the celebrated siege of Calais, and it was probably at this time that cannon were first employed by the English. Camden, in his *Remains*, says, "Certain it is, that King Edward III. used them at the siege of Calais in 1347."

Use of cannon.

Sizes of Edward's ships.

Although from the fact of there being a royal dock-yard at Portsmouth so early as the reign of John, it is probable that the kings of England were possessed of a navy almost from the conquest; yet this roll of Edward's fleet contains the first enumeration of ships belonging to the sovereign, and employed in the service of the state, which occurs in English history; and consequently it is from the reign of Edward III. that the formation of a royal navy must be dated. The king's ships were 25 in number, and were manned by 419 mariners. It appears that the vessels belonging to the sovereign were inferior in force to many of those which were supplied by subjects; for the average number of the crews of the king's ships were 17 men to each vessel, while the average of the fleet was rather above 20. Of course these numbers only include the mariners employed in navigating the vessels, and not the soldiers to be afterwards embarked on board them. Considering the simplicity of the rig of these ships, in comparison to the wilderness of canvas and cordage covering the tall masts of a modern merchantman, there is more reason to be astonished at the large number of hands employed, than at the smallness of the averages, 17 and 20. There is good reason to suppose that the addition of the bowsprit to the rig of ships dates no farther back than late in the reign of Edward III., which is alone quite sufficient to prove the very imperfect state of the navigation at that period, and also to excite astonishment that, with such apparently inadequate means, so much was effected; for history would almost lead us to suppose that, for all the purposes of war and commerce, fleets as proudly or as industriously ploughed the main then as now, "with all appliances and means to boot."

Richard II.

First navigation act.

In the year 1381, the fourth of the reign of Richard II., the first navigation act was passed in England, for the encouragement of the naval interest and the augmentation of our maritime power, by discountenancing the employment of foreign shipping. It enacted, "That for increasing the

History. shipping of England, of late much diminished, none of the king's subjects shall hereafter ship any kind of merchandize, either outward or homeward, but only in ships of the king's subjects, on forfeiture of ships and merchandize, in which ships also the greater part of the crews shall be of the king's subjects." This act was not, however, enforced, permission being given to hire foreign shipping when there were no English ships in readiness.

Royal ships hired by merchants. It has been remarked above, that the royal navy of England must date from the reign of Edward III. There is proof that it continued to be customary for the sovereign to possess ships; they were, however, used both for war and commerce. This practice, which does not at all militate against the existence of a royal navy, appears to have commenced when "large ships" were substituted for the galleys as vessels for war; and it long continued to be usual for merchants to hire shipping from the sovereign for commercial voyages. The proceedings of the privy council, which have been printed by the Record Commission, show

Henry IV. that in June of the year 1400, Henry IV. ordered his "new ship," together with such others as were in the port of London, to proceed against the enemy. There is also a

Letter to Henry V. letter in the Cottonian Library, which has been printed in Ellis's *Collection of Letters*, from John Alcetre to King Henry V., concerning a ship building for that monarch at Bayonne. The letter is of the date of 1419; and as it contains more minute details than might be expected to have descended to us from such an early period, we give the following extract:—"At the makyng of this letter yt was in this estate, that ys, to wetyng xxxvj. strakys in hyth y bordyd, on the weche strakys hyth y layde xj. bemys; the mast beme ys yn leynthe xlvj. comyn fete, and the beme of the hameron afore ys in leynthe xxxix. fete, and the beme of the hameron by hynde is in leynthe xxxiij. fete; fro the onemost ende of the stemme in to the post by hynde ys in leynthe a hondryd iij$^{xx.}$ and vj. fete; and the stemme ys in hithe iiij$^{xx.}$ and xvj. fete; and the post xlviij. fete; and the kele y in leynthe a hondryd and xij. fete; but he is y rotyt, and must be chaungyd."

We have also evidence of the existence of ships which belonged to the monarch, in contradistinction to ships which belonged to the "commons," in the quaint rhymes of an anonymous author of the year 1433, which have been

Libel of English Policie. preserved by Hackluyt, termed *The Prologue of the processe of the Libel of English policie, exhorting all England to keepe the sea, and namely, the narrowe sea, showing what profite commeth thereof, and also what worship and saluation to England, and to all Englishmen.*

"And if I should conclude all by the king
Henrie the Fift, what was his purposing,
Whan at Hampton he made the great dromons,
Which passed other great ships of all the commons;
The Trinitie, the Grace de Dieu, Holy Ghost,
And other moe, which as nowe bee lost.
What hope ye was the king's great intent
Of thoo shippes, and what in minde hee meant:
It was not ellis; but that hee cast to be
Lorde round about environ of the sea."

The term dromond is the corruption of a Levantine term, dromones, imported probably by the crusaders. The dromonds were long row-galleys, but the adopted term dromond was applied generally to all large ships.

Henry's fleet. There is a list of Henry's vessels in the fourth year of his reign preserved in the proceedings of the privy council. His navy then consisted of three "large ships," or "grands niefs," three "carracks," eight barges, and ten balingers. In 1417 it was augmented to three "large ships," eight "carracks," six other ships, one barge, and nine balingers.

Early tonnage. Again, in a letter preserved among the Cottonian manuscripts, and printed in Ellis's collection, it is stated that the Spaniards offered Henry V. two carracks for sale, one of which is described as of a tonnage equal to 1400, and the other to 1000 butts. So energetical was Henry V. in all things relating to his navy, and the consequent increase in the number of the royal ships during his reign was so great, as to have led to the error that before his time the sovereigns of England were not possessed of vessels, but relied wholly upon the aid to be gathered from the different ports of England, or to be hired from foreigners. This is evidently incorrect.

Neglect of the navy. On the death of Henry V. a different line of policy appears to have been adopted; for in May 1423 the king's ships were all sold at Southampton, under a restriction that no foreigner could be a purchaser of them. But it appears that a long period did not elapse before the depressed state of the naval resources of the kingdom, consequent on this injudicious measure, attracted the attention of parliament. The following interesting quotation from the preface of the fifth volume of the *Proceedings of the Privy Council*, printed by the Record Commission, refers to this event:—"In 1443 the attention of parliament was directed to this important part of the national defence (the naval force), and a highly curious ordinance was made for the safeguard of the sea. From February to November eight ships with forestages, or, as they were sometimes called then, as now, forecastles, armed with 150 men each, were to be constantly at sea. Every large ship was to be attended by a barge of 80 men, and a balinger of 40 men. There were also to be 'awaiting and attendant upon them' four 'spynes' or 'spinaces,' with 25 men each. The whole number of men in these 24 ships was 2240."

There is also in the same preface an account of the various kinds of ships which formed the navies of this period, a part of which we shall quote, and by the addition of some further information of the same nature, derived from Froissart, Monstrelet, and other sources, the reader will be enabled to form a tolerably correct opinion as to the state of naval architecture in England previous to and during the fifteenth century.

Ships. *Ships.* "The burthen of the largest ships at that period probably did not exceed 600 tons, though some of them were certainly very large," as, for instance, the vessel built at Bayonne for Henry V., already mentioned. "One which belonged to Hull was released from arrest" (she having been pressed into the king's service), "because she drew so much water that she could not approach within two miles of the coast of Guienne, where the Duke of Somerset's army intended to disembark;" and several notices occur of ships of 300 and 400 tons and upwards. Some had three and others only two masts, with short topmasts, and a "forestage" or "forecastle," consisting of a raised platform or stage, which obtained the name of castle from its containing soldiers, and probably from its having bulwarks. In this part of the ship it appears business was transacted; and in the reign of Edward III., if not afterwards, ships had sometimes one of these stages at each end, as ships "*ove chastiel devant et derere*" are then spoken of. Lydgate, describing the fleet with which King Henry V. went to France after the battle of Agincourt, says,

"Fifteen hundred ships ready there be found,
With rich sails and high topcastle."

This is a confusion of terms. The "topcastles" were not the forecastles, but were castellated enclosures at the mastheads, in which the pages to the officers were stationed during an engagement, in order to annoy the enemy with darts and other missiles; as is frequently mentioned in Froissart, and is represented in the illuminations to his work.

Carracks. *Carracks* "were vessels of considerable burthen, and were next in size to great ships, in which class they indeed were sometimes included. Their tonnage may be estimated by their being in some instances capable of carrying 1400 butts; and the sail of one afforded Chaucer a strange simile expressive of magnitude,

History.

'And now hath Sathanas, saith he, a tayl
Broder than of a carrike is the sayl.'

Though occasionally armed and employed against the enemy, they were more generally used in foreign trade."

Charnock says that the first carrack which was built in England was built for a merchant, John Tavenier of Hull, who was consequently honoured by Henry VI. with distinguished favour; and she was licensed in 1449 with particular privileges to trade through the Straits of Morocco. The king also ordered her to be called the "Grace Dieu Carrack." The license states her to have been built "by the help of God and some of the king's subjects."

Barges. *Barges* "were a smaller kind of vessel and of different construction from ships, though, like them, they sometimes had forecastles. Those appointed to protect the seas in 1415 were of 100 tons burthen, and contained forty mariners, ten men-at-arms, and ten archers; whilst the ships employed on the same occasion were of 120 tons, and had forty-eight mariners, twenty-six men at arms, and twenty-six archers each. Four large barges and two balingers were capable of holding 120 men-at-arms and 480 archers and sailors."

Balingers. *Balingers* "were still smaller than barges, had no forecastle, and sometimes contained about forty sailors, ten men-at-arms, and ten archers." Froissart makes frequent mention of "balniers," "balleniers," which he describes "as drawing little water, and being sent in advance to seek adventures, in the same manner as knights and squires, mounted on the fleetest horses, are ordered to scour in front of an enemy, to see if there be any ambuscades." Monstrelet speaks of one vessel that was employed by Louis XI. to abduct the Count de Charolais, by the two names ballenier and balayer. It is not improbable that the name is derived from the French word *baleine*, and that its origin was similar to that of our English name whaler. The whale-fishery in Biscay was of a very early date.

Galleys. *Galleys* "are frequently mentioned at a very early period; and in the 5th Rich. II., 1381, the Commons complained that no measures had been taken to resist the enemy, who had attacked the English at sea with their barges, galleys, and other vessels. In 1405 Henry IV. directed his council to apply to the King of Portugal to lend him his galleys to assist the English navy against the French."

In Sir Grenville Temple's Travels in Greece and Turkey the following description of a Maltese galley, or, more correctly, galleas, made from an old model preserved there, will be found:—"These galleys measured 169 feet 1 inch in length, and 39 feet 6 inches in breadth. They had three masts with latine sails, and were propelled by forty-nine oars, each 44 feet 5 inches long. Their armament consisted of 1 thirty-six pounder, 2 of twenty-four, and 4 of six, all on the forecastle, which in those days had in reality some appearance of a castle. On each side of the vessel, aft of the forecastle, were 4 six-pounders." The total crew, including galley-slaves, consisted of 549 persons.

Galleas. The *Galleas* and the *Galleon* appear to have been successive improvements on the original galley, rendered necessary by the introduction of cannon into naval warfare. The artillery introduced on board the early galleys was placed either before or abaft the rowers, and to fire in the direction of the length. In the galleas, a description of vessel first used at the battle of Lepanto, guns were also placed between the rowers, to fire from the broadside. Evelyn describes the galleases he saw at Venice (1645) as being "vessels to rowe of almost 150 foote long and 30 wide, not counting prow or poop, and contain twenty-eight banks of oares, each seven men, and to carry 1300 men, with three masts." In the galleon the oars ceased to be the principal means of propulsion, and if used at all, were only so as occasional aids. The galley and galleas had overhanging topsides for the accommodation of the oars. In the galleon, on the contrary, the topsides "tumbled home" to so extraordinary an extent, that the breadth at the water was twice that at the topside, a fashion which has continued, but in a much less degree, to the present time.

History.

Spynes or spynaces. *Spynes* or *spynaces*, "now called pinnaces, seem to have been large boats, capable of holding twenty-five men, and were probably used for swiftness. To these must be added crayers, hulks, gabarres or gabbars, a kind of flat-bottomed boat, used in shallow rivers." The French still continue to apply the term "gabarre" to store-ships.

Playtes and smaller vessels. "Playtes, cogships, whence perhaps cogs and coggles are derived; farecrofts, passagers, which were perhaps boats used between England and France; and cock-boats, a small boat which attended upon all kinds of ships. The whole of these vessels were employed in conveying goods or passengers, and most of them on rivers or in the coasting trade. The ships, carracks, barges, balingers, and galleys, were employed equally for commerce or for war. When sent against the enemy, soldiers were put on board of them; and it is most likely they were at all times partly manned by soldiers. In foreign voyages they usually sailed in convoys; and it was a very ancient custom for the masters and sailors to elect their own admiral."

Foists or foysts. In Burchett's account of the unfortunate action in the Bay of Conquet, in 1513, in which the Lord High Admiral, Sir Edward Howard, lost his life, four *foists* are mentioned as forming a part of the French force. They were probably vessels of a similar character with the galley, but smaller in size. About the beginning of the seventeenth century, "carracks," "galleons," and "tall shippes," appear to have become synonymous terms.

Hulks. The term hulk originally was applied in a different sense from that which is stated in the part of the foregoing remarks which we have quoted from the preface to the proceedings of the privy council. Frequent allusion is made to hulks in documents of the fifteenth and sixteenth centuries. In a letter from Sir Thomas Seymour to the privy council, dated the 13th of November 1544, when in command of the "shipes whyche was a poyntede to kepe the Narrow Sees," vindicating himself for putting back on account of a storm, there is the following passage, from which it might almost be inferred that hulk was a general name synonymous with ships:—"Thre holkes that come after me colde nott gett syght thereof (the 'Eylle of Wyght') tyll they warre in a bay on the est syde of the Eylle, of the whyche Mr Strowd, Bramston, and Battersebe of the garde, God rest their sowles, was in on of them, whyche holke brake all her ankeres and cabelles, and she brake all to peses on the shorr, and but 41 of 300 saved a lyve. The other two rode out the storme; whyche lasted all that nyght and the next day. My brother (Sir Hy Seymour) and John Roberds of the garde, tryde the sees all the furst nyght, and the next day cam into Dartemouth haven, wharre my brothers holke strake on a roke and brest all to peses; but God be praysede, all the men warre savede, savying thre; and a nother new holke that tryde the sees that nyght brake thre of her bemes, and with moche ado came into the Wyght."

Again, in a letter from Lord Viscount Lisle, Baron Malpas, the Lord High Admiral of England, to Henry VIII., there is an announcement, that "their is cum into the Downes 30 sayle of hulkses, whereof sum be tall shipes." And again, in a letter from the same to the Lord Chamberlain, Lord St John, he speaks of having detained "3 grate hulkes bound, as they say, for Lusshborne, the leste of y^m 500 tunnes." And again, from the same to the same, he speaks of his former letter and the "goodly hulkes," and says, "sithens that tyme I have stayed other too, which in beautye and well appoynting are beyond the others. That I have last stayed ys a shipe of 600 at the least, and hath

History.

5 toppes, and she ys of the town of Dansick, and ladon in Flanders for Lusshbourne."

State mercantile shipping. William Canynge.

The importance of the mercantile shipping of England during the fifteenth century must have been considerable. About the middle of it flourished the celebrated William Canynge, a merchant of Bristol, who built the church of St Mary's, Redcliff, in that city, in which church he was buried in 1474. This man appears to have been much in advance of the rude times in which he lived. His mercantile transactions were on so extensive a scale, and carried on in vessels of such large size, that they must have had an important influence in improving the navies of the period. The information which has descended to us respecting him is therefore not only a fact of much historical interest, but is one which is intimately connected with, and most materially affects, our subject. He was a great patron of the arts, a friend and protector of genius, and eminent for his virtue and piety. From an inscription upon his tomb, a tradition has become current, that Edward IV. took 2470 tons of shipping from him, he having "forfeited the king's peace;" and for the obtaining of which again, it is stated that Edward accepted these ships instead of a fine of 3000 marks. The *Itinerary* of William of Worcester, preserved in the library of Bennett College, Cambridge, gives the names of Canynge's vessels, among which are the Mary and John of 900 tons, Mary Redcliff of 500 tons, and Mary Canynge of 400 tons. The same authority gives the names and tonnage of other large ships belonging to Bristol merchants, among which are the John of 511 tons, and the Mary Grace of 300 tons. If there be any truth in the tradition of the confiscation of the shipping, it is probable that the inscription on the tomb may refer to some act of Canynge's in favour of the house of Lancaster, as he appears to have enjoyed the favourable opinion of Henry VI. Another account, which, it is said, is authenticated by the original instrument in the Exchequer, states that this Canynge assisted Edward IV. with a loan, and received in return a license to have 2470 tons of shipping free of imposts. In Corry's *History of Bristol* it is said, "the commerce and manufactures of Bristol appear to have made considerable progress during the fifteenth century, about the middle of which flourished the celebrated Canynge. This extraordinary man employed 2853 tons of shipping, and 800 mariners, during eight years. Two recommendatory letters were written by Henry VI. in 1449, one to the master-general of Prussia, and the other to the magistrates of Dantzic, in which the king styles Canynge his beloved eminent merchant of Bristol."

Doubts as to accuracy in estimating size of ships.

Some doubt must always remain as to the actual size of the shipping of this remote period, as we cannot ascertain the bulk that was then considered as equivalent to a ton. It is probable that the tonnage was estimated according to the number of butts of wine that a vessel could carry. For we find references to ships sometimes by tonnage, and sometimes by the "portage" of so many butts.

This, however, is only a question as to exactness of size. In whatever way measured, Canynge's ships must have been of very considerable dimensions. It is rather extraordinary, that at the unsettled period in question Bristol should have enjoyed such a state of commercial prosperity as the ownership of such shipping as that enumerated by William of Worcester necessarily involves. Bristol, for many centuries, was only second in mercantile importance to London; but the civil wars which distracted the kingdom during a great part of the fifteenth century must have much retarded the increase both of the military and the mercantile navy of England; and only when order was again re-established by the accession of Henry VII. to the throne, in 1485, could men's minds revert from the internal excitement of party strife to external affairs.

Henry VII.

In this interval, in which England was torn by the wars of the houses of York and Lancaster, naval science had made more rapid strides than in any previous period of similar duration. The compass was not only known but was generally adopted. Navigators could take observations by the use of an instrument called the astrolabe, invented by the Portuguese. The Spaniards and Portuguese were sufficiently advanced in the art of navigation to sail on a wind, and their smaller vessels, at least, were adapted for this manœuvre. New maritime states had started into existence. The Netherlands, until then scarcely known, was, under the Duke of Burgundy, the most formidable naval power in the north of Europe. "His navy," says Philip de Commines, "was so mighty and strong, that no man durst stir in those narrow seas for fear of it, making war upon the king of France's subjects, and threatening them everywhere; his navy being stronger than that of France and the Earl of Warwick joined together." Venice, in 1420, according to Denina, in his *Revolutions of Italy*, supported 3000 merchant-ships, on board of which were 17,000 seamen. They employed 300 sail of superior force, manned by 8000 seamen; had forty-five carracks, with 11,000 men to navigate them; and her arsenals employed 16,000 carpenters. Portugal had pushed her discoveries round the Cape, and Spain had added America to the world.

Progress of naval improvement. Compass. Astrolabe. Netherlands. Venice.

The progress of discovery by the Portuguese to the south and east, and by the Spaniards to the west, in the voyages of Columbus, with the consequent rapid increase in the importance of these two powers, and the influence of their discoveries on the state of Europe, renders the fifteenth century probably the most important of modern history. In it was given the death-blow to the increase of the Saracenic power, and to that of the Mediterranean states. The Turk, the Venetian, and the Genoese, had hitherto been the monopolizers of the commerce of the east. The discovery of the passage round the Cape of Good Hope opened this trade to all nations. The commercial sceptre, and consequently the military sceptre, hitherto shared by the Turk, passed wholly from the infidel to the believer. The crescent sank before the cross.

Portugal. Spain. Passage round the Cape of Good Hope.

There can be no doubt, also, that the "*tormentas*" of the "*grão Cabo de boa Esperāça*," were a means of great improvement in naval architecture; for, in consequence of the representations of Bartholomew Diaz, John II. of Portugal ordered ships to be constructed for the especial purpose of contending with the stormy seas of the Cape of Good Hope. The ships were built to form the squadron of Vasco de Gama, and were of small tonnage, from the very proper idea that small vessels were more adapted to prosecute researches in unknown seas than those of a large size, and consequent increased draught of water.

Its influence on naval architecture.

The squadron of Vasco de Gama consisted of three ships and a caravella. One of the ships was of the burthen of 200 tons, another 120, and the third 100; the caravella was of 50 tons. The largest of the ships was a victualler; the smallest was intended to prosecute discovery up creeks and shallows; and the other was for a display of force. As it is evident that it was not increase of dimensions which was to be the object in designing new vessels, the direction of improvement must have been towards perfecting their forms, strengthening their frames, and adding to the efficiency of their *materiel*. Portugal by these means became the most advanced state of Europe in knowledge of the art of ship-building; for it was long supposed that the passage to India required ships such as the Portuguese alone could build. Spain, in her career of discovery, conquest, and colonization across the mighty waters of the Atlantic, as if to assimilate the means to the vastness of her achievements, rapidly acquired the art of constructing ships of very large dimensions; and as long as she possessed a marine, her ships maintained this superiority.

Squadron of Vasco de Gama.

History.

State of naval affairs in England.

There is a curious instance of the light in which naval enterprises were considered in England at this time, notwithstanding the earnest desire of the monarch to re-establish his navy, which had necessarily suffered from the long civil wars. A letter from Henry VII. to the Pope is preserved in the Cottonian Library, excusing himself from sending succour against the Turk, from which the following is a quotation:—"The Galees commying from Vennest o England be commonly vij. monethes sailying, and sometimes more;" and again, "it should be May or they should be ready to saill, and it shall be the last end of September or the said shippes shuld passe the Streits of Marrok; and grete difficultie to fynde any Maryners hable to take the rule and governance of the said shippes sailying into so jeopardous and ferre parties."

Henri Grace à Dieu.

There is a drawing extant in the Pepysian Library in Magdalen College, Cambridge, of the Henri Grace à Dieu, built by the order of Henry VII., which Charnock has engraved in his *History of Marine Architecture*, and argues as to the general authenticity of the representation. He says, "this vessel may be termed the parent of the British navy. This celebrated structure, the existence of which is recorded in many of the ancient chronicles, cost the king, by report, nearly 14,000 pounds."

Early origin of naval terms.

From this drawing may be traced the derivation of one or two names which have been preserved even to the present hour; as, for instance, the "yard-arm," no doubt from the ends of the yards being armed with an iron hook. The castellated work from which has arisen the term "forecastle" is earlier than this; and the buckler-ports are most probably derived from a yet earlier period, when the bucklers of the knights were ranged along the sides of the ship, as they are represented in the illustrations of Froissart, and of the early chroniclers, and even in the Bayeux Tapestry.

"The masts were five in number, inclusive of the bowsprit, an usage which continued in the first-rates without alteration till nearly the end of the reign of King Charles I.; they were without division, in conformity with those which had been in unimproved use from the earliest ages. This inconvenience it was very soon found indispensably necessary to remedy, by the introduction of separate joints, or top-masts, which could be lowered in case of need."

The drawing shows two tiers of ports. The introduction of port-holes is said to be an improvement due to a French ship-builder of Brest, named Descharges, in the reign of Louis XII., and about the year 1500. If the drawing be authentic, the correctness of this appropriation of the merit of the introduction of port-holes may be questionable.

Again, if the drawing be a correct representation of the vessel, she would have been in danger of upsetting, excepting in calm weather, and when her course was with the wind. In fact, as yet the large ships of war of England were not at all adapted to sail on a wind, and were very ill provided with such sails as would enable them to do so; they had therefore nothing to fear from the result of a measure which could not be put into execution. The fleets of war seldom ventured out of port excepting in the summer months, and then only when the wind was favourable to their intended course. But very shortly after the date of the building of the Henri Grace à Dieu, great improvement took place, and in the reign of Henry VIII. there is evidence to prove that sailing on a wind formed one of the qualities of the vessels composing his fleets. This fact appears to throw some doubt upon the correctness of the drawing, for it must have required ships widely different from any of which that would at all give an idea, to have performed the evolution of tacking or wearing; and as the Henri Grace à Dieu was in all probability the same ship that on the accession of Henry VIII. was called the Regent, she must have formed one in fleets which were capable of performing these manœuvres. It is true that she may have been altered to adapt her to these new requirements of an improved system of seamanship; and it must also be said, that she was burned in an action with the French fleet, which occurred as early as the fourth year of the reign of Henry VIII.

History.

Henry VIII. Sailing on a wind.

Though it is out of the question that ships with the enormous top-hamper which, on the evidence of all the drawings extant, still continued to be the fashion, could have made much progress in sailing on a wind, the letters of the time extant corroborate the statement made; for they begin to contain references to this improvement in navigation. In a letter from Sir Edward Howard, "Lord Admiral," to King Henry VIII., upon the state of the fleet, A.D. 1513, preserved in the Cottonian Library, and published in Ellis's collection, the following passage occurs:—"Ye commanded me to send your grace word how every shipp dyd sail; and this same was the best tryal that cowd be, for we went both slakyng and by a bowlyn, and a cool acros and abouet in such wyse that few shippes lakkyd no water in over the lee wales." The Lord High Admiral Lisle, in one of his letters (1545), says the small vessels of his fleet could "lye best by a wynde;" and in 1567 we have conclusive proof that there were "fore and aft," indeed "cutter-rigged" vessels on the British seas; as in a map of Ireland of that date, published in the state-papers, two such vessels are represented, for the purpose, apparently, of indicating regular packets from England to Ireland.

It has been very generally supposed, on the authority of Sir Walter Raleigh, that the "knowledge of the bowline" was a discovery in navigation made shortly before his time; but is is probable that there were, even from the time of the Northmen, craft so rigged as to be capable of sailing on a wind. Froissart mentions, in several instances, "a vessel called a Lin, which sails with all winds, and without danger;" and again, "a vessel called a Lin, which keeps nearer the wind than any other." Boats with a rig adapted for this manœuvre are also represented in engravings of a very early date. In the plates of Breydenbach's *Voyage to Palestine*, which was published in 1483, boats and small vessels are represented with lateen sails; and in Braun's *Civitates Orbis Terrarum*, published in 1572, sprit-sails are met with. It is quite certain, however, that sailing on a wind was by no means a general quality possessed by the ships of war, or to any extent even by the greater portion of the larger shipping, until about the reign of Henry VIII. One other instance may be adduced in the account of the loss of the Mari Rose, a ship of the "portage of 500 tons," not so much to corroborate the fact of sailing on, a wind as to show that the two innovations, the introduction of port-holes and the "knowledge of the bowline," were in advance of the qualities of the large ships of war of the time. Sir Walter Raleigh says that, "in King Henry VIII.'s time, at Portsmouth, the Mari Rose, by a little sway of the ship in casting about, her ports being within sixteen inches of the water, was overset and lost."

Loss of the Mari Rose.

The loss of this ship has been the means of giving another interesting insight into the comparatively low state of nautical skill in England at this period, namely, the middle of the sixteenth century. In a letter among the state-papers published under the direction of the Record Commission, addressed by the Duke of Suffolk to Sir William Pagett, "chief secretary to the kinge's highnes," dated the 23d of July 1545, and containing a schedule of things necessary to be had for the raising of the Mari Rose, one item is "fifty Venyzian maryners and one Venyzian carpenter;" the next item is "sixty Englisshe maryners to attende upon them." It would also appear that the attempt was to be made under the direction of an Italian, as the conclusion of the schedule is, "Item, Symond, petrone and master in the Foyst, doth aggrie that all thyngs must be

had for the purpose aforesaid." The attempts, however, all failed; the wreck of the Mari Rose remains to this day at Spithead, and so lately as August 1836, several of her brass cannon, of most exquisite workmanship, were recovered from the sea by the enterprise and ability of an Englishman of the name of Deane.

Minutiæ of ship-building at this period.

Some idea of the detail of ship-building rather before this period may be obtained from an account of a vessel built by James IV. of Scotland, at the close of the fifteenth or the beginning of the sixteenth century. The extract is from Charnock, but he has not mentioned his authority. "The king of Scotland rigged a great ship, called the Great Michael, which was the largest and of superior strength to any that had sailed from England or France; for this ship was of so great stature, and took so much timber, that, except Falkland, she wasted all the woods in Fife which were oakwood, with all timber that was gotten out of Norway; for she was so strong, and of so great length and breadth, all the wrights of Scotland, yea, and many other strangers, were at her device by the king's command, who wrought very busily in her; but it was a year and a day ere she was completed. To wit, she was twelve score feet of length, and thirty-six foot within the sides; she was ten foot thick in the wall and boards, on every side so slack and so thick that no cannon could go through her. This great ship cumbered Scotland to get her to sea. From that time that she was afloat, and her masts and sails complete, with anchors offering thereto, she was counted to the king to be thirty thousand pounds expense, by her artillery, which was very great and costly to the king, by all the rest of her orders. To wit, she bare many cannon, six on every side, with three great bassils, two behind in her dock and one before, with three hundred shot of small artillery, that is to say, myand and batterd falcon, and quarter falcon, flings, pestilent serpentens, and double dogs, with hagtor and culvering, corsbows and handbows. She had three hundred mariners to sail her, she had six score of gunners to use her artillery, and had a thousand men of war, by her captains, shippers, and quarter-masters."

Large Swedish ship.

Several of the writers of this period mention the fact of a Swedish ship of extraordinary dimensions being built in the middle of the sixteenth century, and which was burned in an action between the Swedes and Danes in 1564. Chapman has given an estimate of the dimensions of this vessel. She was called the Makalos (by Charnock, Megala). According to Chapman, she was 168 English feet in length and 43 English feet in breadth, an immense vessel for that period. Her armament was 173 guns, 67 only of which could be considered as cannon, the remainder being merely swivels.

Royal dockyards.

Henry VIII. was deeply sensible of the necessity of a permanent and powerful naval force, and established the navy office, and also several dockyards for building and repairing the ships of the royal navy. Among these were Woolwich, Deptford, and Chatham. He also greatly added to and improved the dockyard at Portsmouth. He invited from foreign countries, particularly from Italy, the commercial cities of which were still in advance of the rest of Europe in the maritime arts, as many skilful foreigners as he could allure, either by the hope of gain or by the honours and distinguished countenance he paid to them. The following extract is from a report made to James I. in the year 1618, and published in the *Archæologia*. It was made in answer to a commission issued by that monarch to the several master-builders.

Edward VI.

The minority of Edward VI., and the civil and religious strife which distracted the kingdom during the reign of Mary, depressed the resources of the state, and evidently much checked the progress of its maritime strength. The report says, "In former times our kings have enlarged their dominions rather by land than sea forces, whereat even strangers have marvelled, considering the many advantages of a navy; but since the change of weapons and fight, Henry VIII., making use of Italian shipwrights, and encouraging his own people to build strong ships of war, to carry great ordnance, by that means established a puissant navy, which in the end of his reign consisted of 70 vessels, whereof 30 were ships of burthen, and contained in all 10,550 tons, and 2 galleys. The rest were small barques and row-barges, from 80 tons downwards to 15 tons, which served in rivers and for landing of men. Edward VI., in the sixth year of his reign, had but 53 ships, containing in all 11,005 tons, with 7995 men, whereof only 28 vessels were above 80 tons each. Queen Mary had but 46 of all sorts."

Defects of the ships of this period.

There is one peculiarity about the fleets of this time, which exemplifies the defects of their design in a very remarkable feature. It is, that the ships built for the royal navy appear only to have been adapted for the lodgment of the soldiers and mariners, with their implements of war, and the necessary stores for navigation. The provisions were carried in an attendant vessel, called a "victualler," of which there was one attached to each of the large ships of war in the fleet, or to several of the smaller size. The hold appears to have been principally occupied by the "cook-room," the inconvenience of which arrangement, though much complained of, was general when Sir Walter Raleigh, in his *Discourse on the Royal Navy and Sea Service*, recommended that it should be removed to the forecastle; and even so lately as 1715, several men of war had "cook-rooms" in their holds. There is also no doubt that the enormous quantity of ballast which was rendered necessary by the immense top-hamper of these ships, and the space which it occupied, from being shingle, left but little room for the stowage of any quantity of provisions. In the ships built for commerce, this defect does not appear to have existed, as in fleets composed of the king's and of private shipping, those ships only which belonged to the royal navy had these attendant victuallers. The cook-rooms in the merchant shipping were under the forecastle; and they had less top-hamper, as less accommodation was required for officers.

Epoch in naval architecture.

Although the comparative inefficiency of the vessels may be commented on, it will be apparent that that period in the history of naval architecture and of navigation has now been entered on in which, though still in their infancy, these arts may be considered as perfect in all but the maturity to be acquired by the experience of years. The mariner's compass was known; the theory of taking observations was understood, and the practice of it in the course of being perfected; and therefore the longest voyages could be undertaken with comparative certainty and safety. Besides this, the ships, though still imperfect, were becoming gradually manageable machines, and had ceased to be the cumbrous masses of the preceding ages, which, with few exceptions, were capable of little more than of being driven before the wind.

Three epochs in the maritime history of England.

If the contents of the foregoing pages be considered, there will appear to be three epochs in the maritime history of England; the first commencing with the introduction of galleys by Alfred, and ending with the reign of Edward III., before whose time these galleys and vessels, propelled by oars, were the chief instruments of navigation; the second ending with the reign of Henry VII., during which period, though sailing vessels were used for the purposes both of war and commerce, they were comparatively at the mercy of the winds, and, speaking generally, could sail only when they blew both fairly and gently; the third epoch has been already noticed.

From the extract of the report of the builders, the state of the navy during the reigns of Edward VI. and of Mary

History. Elizabeth. Action with Spanish Armada.

will be seen. It is known, therefore, that when Elizabeth ascended the throne, the marine of England, both military and mercantile, was in a very depressed state. The successful enterprise of Drake, and the fear of the Spanish Armada, aroused the energies of the country, and the force collected to resist the invasion amounted to 197 vessels of various descriptions, of the aggregate burthen of nearly 30,000 tons, 34 of which, measuring together 12,600 tons, composed the royal navy. It is true, that by far the larger portion were of small force. One only, the Triumph, was of 1100 tons; another, the White Bear, was of 1000 tons; two were of 800 tons, 3 of 600, six of 500, and five of 400; sixty-six were under 100 tons; and fifteen were victuallers, of which the tonnage is not mentioned. There are also seven other vessels included in the 197 which have no tonnage assigned them; but they must have been of small size, the number of mariners on board the whole seven being only 474. We have very conclusive means of comparing the Spanish with the English ships, and also of judging how very little naval arrangements were then understood, from their imperfect state even on board a fleet which had occupied the whole attention of the Spanish authorities for a space of three years, exemplified in the following anecdote. Burchett, in his account of the action of the 23d of July 1588, says, "The great guns on both sides thundered with extraordinary fury, but the shot from the high-built Spanish ships flew over the heads of the English without doing any execution; one Mr Cock being the only Englishman who fell, while he was bravely fighting against the enemy in a small vessel of his own."

Three-decked ships.

The Spaniards appear to have been the first to introduce a third tier of guns, the earliest mention of a three-decker being the Philip, a Spanish ship engaged in the action off the Azores in 1591, with the Revenge, commanded by Sir Richard Greenvil. The following armament of the Philip is extracted from a most spirit-stirring account of this tremendous action, which was written by Sir Walter Raleigh, and has been preserved by Hackluyt. "The Philip carried three tire of ordnance on a side, and eleven pieces in euerie tire. She shot eight forth right out of her chase, besides those of her stern portes."

The English do not appear to have followed the example set by the Spaniards; for, during the long reign of Elizabeth, the ships of the royal navy were not much, if at all, increased in their dimensions, which was probably owing to the triumphant successes of her fleets, though they were composed of ships generally much smaller in size than those opposed to them. From the list of the royal navy at the time of her death, in 1603, given by Sir William Monson in his tracts, of 42 ships composing the navy, there were then only two ships of 1000 tons, three of 900, three of 800, two of 700, four of 600, four of 500, and there were eight under 100 tons burthen. Two of these ships, the Triumph and the White Bear, are rated in this list each at 100 tons less burthen than in the list of the fleet in the year 1588, already noticed.

The mercantile marine was also greatly improved and increased during the reign of Elizabeth. This wise monarch did all in her power to encourage foreign trade; and she honoured Drake by knighting him on board his own vessel at Deptford, after his return from circumnavigating the globe. The celebrated Sir Walter Raleigh, under a charter granted by her in 1584, commenced trading with America, and his successes, with those of others, in trade, as well as in the capture of richly laden Spanish merchantmen, prove the superiority of the English ships of this period. In 1600 the East India Company obtained their charter from Elizabeth, and merchant-ships, which proved the precursors of a fleet of the finest merchantmen, were immediately built by them for this distant traffic.

Shortly after the accession of James to the throne, several commissions were appointed to inquire into the state of the navy. From that of the year 1618 a very voluminous report emanated, of which the following is an extract, that affords an example of the state of knowledge on naval architecture at that time:—"The next consideration is the manner of building, which in shipps of warr is of greatest importance, because therein consists both their sayling and force. The shipps that can saile best can take or leave (as they say), and use all advantages the winds and seas does afford; and their mould, in the judgment of men of best skill, both dead and alive, should have the length treble to the breadth, and breadth in like proportion to the depth, but not to draw above 16 foote water, because deeper shipps are seldom good saylers, and ever unsafe for our rivers, and for the shallow harbours, and all coasts of ours, or other seas. Besides, they must bee somewhat snugg built, without double gallarys, and too lofty upper workes, which overcharge many shipps, and make them coeme faire, but not worke well at sea.

History. James I. Report of commission.

"And for the strengthening the shipps, wee subscribe to the manner of building approved by the late worthy prince, the lord admll., and the officers of the navy (as wee are informed), on those points.

"1. In makeing 3 orlopes, whereof the lowest being placed 2 foote under water, both strengtheneth the shipp, and though her sides bee shott through, keepeth it from bildgeing by shott, and giveth easier meanes to finde and stopp the leakes.

"2. In carrying their orlopes whole floored throughout from end to end, without fall or cutting off ye wast, which only to make faire cabbins, hath decayed many shipps.

"3. In laying the second orlope at such convenient height that the portes may beare out the whole fire of ordinance in all seas and weathers.

"4. In placeing the cooke roomes in the forecastle, as otherr war shipps doe, because being in the midshipps, and in the holds, the smoake and heate soe search every corner and seame, that they make the okam spew out, and the shipps leaky, and soone decay; besides, the best roome for stowage of victualling is thereby soe taken up, that transporters must be hyred for every voyage of any time; and, which is worst, when all the weight must bee cast before and abaft, and the shipps are left empty and light in the midst, it makes them apt to sway in the back, as the Guardland and divers others have done."

This commission was followed by several others during this and the succeeding reign, and from their reports arose many regulations tending much to the improvement of the navy, although the expenses incurred were, ostensibly at least, in part the means of causing the subsequent revolution.

Mercantile shipping of this period.

In the early part of the reign of James I. the mercantile navy of England was reduced to a very low state, most of the commerce being carried on in foreign bottoms. The incitement offered by the advantageous trade which the Dutch had long engaged in to India at length aroused the nation, and the formation of the East India Company, which was the act of James, was followed by the building of the largest ship that had yet been constructed for the purposes of commerce, at least in England. The king dined on board of her, and gave her the name of the Trade's Increase. She is reported to have been of the burthen of 1200 tons. The impetus once given, before the end of the reign of James an important mercantile navy was owned by British merchants.

Trade's Increase.

Shipwrights' Company.

Another interesting fact connected with this reign is the founding of the Shipwrights' Company, in the year 1605, and which was incorporated by a charter granted to the "Master, Warden, and Commonality of the Art or Mystery of Shipwrights," in May 1612. Mr Phineas Pett was the first master. The draughts for the ships of the royal

navy were subsequently ordered to be submitted to this company for approval previously to being built from. They also had jurisdiction over all builders, whether of the royal navy or of merchant-shipping.

Draughts of ships of royal navy.

Royal Prince.

In 1610 the Royal Prince was launched; she was the largest ship which at that time had been built in England, and was also a most decided improvement in naval architecture. The great projection of the prow, a remnant of the old galley, was for the first time discontinued, and the stern and quarters assimilated more to those of a modern ship than to any which had preceded her. She is thus described in Stow's *Chronicles*:—"A most goodly ship for warre, the keel whereof was 114 feet in length, and the cross-beam was 44 feet in length; she will carry 64 pieces of ordnance, and is of the burthen of 1400 tons. The great workmaster in building this ship was Master Phineas Pett, Gentleman, some time master of arts at Emanuel College, Cambridge."

Phineas Pett.

The same gentleman, Mr Phineas Pett, continued the principal engineer of the navy during the reign of Charles. The family of the Petts were the great instruments in the improvement of the navy, and, if the term may be allowed, of modernizing it, by divesting the ships of much of the cumbrous top-hamper entailed on them from the castellated defences which had been necessary in, and which yet remained from, the hand-to-hand encounters of the middle ages; and it is probable that, but for the taste for gorgeous decoration which prevailed during the seventeenth century, this ingenious family would have been able to effect much more; as it was, they decidedly rendered England pre-eminently the school for naval architecture during the time they constructed its fleets. This family can be traced as principal engineers for the navy from about the middle of the fifteenth century to the end of the reign of William III.

The Petts.

First frigate.

Evelyn, in his *Diary*, relating a conversation, says, "Sir Anthony Deane mentioned what exceeding advantage we of this nation had by being the first who built frigates, the first of which ever built was that vessell which was afterwards called the Constant Warwick (built in 1646), and was the work of Pet of Chatham, for a trial of making a vessell that would sail swiftly. It was built with low decks, the guns lying near the water, and was so light and swift of sailing, that in a short time she had, ere the Dutch war was ended, taken as much money from privateers as would have laden her." The dimensions of this vessel are given in Pepys's *Miscellanies* as follows: length of the keel 85 feet, breadth 26 feet 5 inches, depth 13 feet 2 inches, and 315 tons burthen; her highest number of guns" 32, and of crew 140.

Peter Pett.

Peter Pett, who built the Constant Warwick, was the son of Phineas Pett. He caused the fact of his being the inventor of the frigate to be recorded on his tomb. He was also the builder of the Sovereign of the Seas, in 1637, which was the first three-decker built in England. Her length over all is stated to have been 232 feet, her length of keel 128 feet, her main breadth 48 feet, and her tonnage 1637. Heywood describes her in the following terms:—"She hath three flush deckes and a forecastle, an halfe decke, a quarter decke, and a round-house. Her lower tyre hath thirty ports, which are to be furnished with demi-cannon and whole cannon throughout, being able to beare them. Her middle tyre hath also thirty ports for demi-culverin and whole culverin. Her third tyre hath twentie-sixe ports for other ordnance. Her forecastle hath twelve ports, and her halfe decke hath fourteene ports. She hath thirteene or foureteene ports more within board for murdering peeces, besides a great many loope-holes out of the cabins for musket shot. She carrieth, moreover, ten peeces of chase ordnance in her right forward, and ten right aff; that is, according to land service, in the front and the reare. She carrieth eleaven anchors, one of them weighing foure thousand foure hundred, &c.; and according to these are her cables, mastes, sayles, cordage, which, considered together, seeing Majesty is at this infinite charge, both for the honour of his nation, and the security of his kingdome, it should bee a spur and encouragement to all his faithful and loving subjects to bee liberall and willing contributaries towards the ship money."

First three-decker.

Of this ship, Fuller, in his *Worthies*, says, "The Great Sovereign, built at Woolwich, a leiger ship for state, is the greatest ship our island ever saw; but great medals are made for some grand solemnity, while lesser coin are more current and passable in payment." She was afterwards cut down one deck, and remained in the service, with the character of the best man-of-war in the world, until the year 1696, when she was accidentally burnt at Chatham.

Sir Walter Raleigh's works: *Invention of Shipping; Concerning the Royal Navy and Sea-Service.*

About this time, 1650, appeared the first work connected with naval improvement ever written in this country, and by no less celebrated an author than Sir Walter Raleigh. It is very probable that his two discourses, the one on the *Invention of Shipping*, the other *Concerning the Royal Navy and Sea-Service*, had great influence in creating the interest which was evidently taken about this period in the improvement of the navy. Sir Walter says, "Whosoever were the inventors, we find that every age had added somewhat to ships and to all things else. And in my owne time the shape of our English ships hath been greatly bettered. It is not long since the striking of the top-mast (a wonderfully great ease to great ships both at sea and harbour) hath been devised. Together with the chaine-pumpe, which takes up twice as much water as the ordinary did, we have lately added the bonnett and the drabler. To the courses we have devised studding-sayles, top-gallant-sayles, sprit-sayles, top-sayles. The weighing of anchors by the capstane is also new. We have fallen into consideration of the length of cables, and by it we resist the malice of the greatest winds that can blow; witnesse our small Milbroke men of Cornewall, that ride it out at anchor half seas over betweene England and Ireland all the winter quarter; and witnesse the Hollanders that were wont to ride before Dunkirke with the wind at north-west, making a lee-shore in all weathers; for true it is that the length of the cable is the life of the ship in all extremities; and the reason is, because it makes so many bendings and waves as the ship riding at that length is not able to stretch it, and nothing breaks that is not stretched. In extremity, we carry our ordnance better than we were wont, because our nether-overloops are raised commonly from the water, to wit, betweene the lower part of the port and the sea. We have also raised our second decks, and given more vent thereby to our ordnance, tying in our nether-overloope.

"We have added crosse pillars in our royall ships to strengthen them, which being fastened from the kelson to the beames of the second decke, keep them from settling or from giving away in all distresses.

"We have given longer floares to our ships than in elder times, and better bearing under water, whereby they never fall into the sea after the head, and shake the whole body, nor sinck sterne, nor stoope upon a wind, by which the breaking loose of our ordnance, or the not use of them, with many other discommodities, are avoided. And to say the truth, a miserable shame and dishonour it were for our shipwrights, if they did not exceed all other in the setting up of our royall ships, the errors of other nations being farre more excusable than ours. For the kings of England have for many years been at the charge to build and furnish a navy of powerfull ships for their owne defence, and for the wars only; whereas the French, the Spainards, the Portugalls, and the Hollanders (till of late), have had no proper fleete belonging to their princes or states.

"Only the Venetians for a long time have maintained their arsenal of gallyes, and the kings of Denmark and

History.

Sweden have had good ships for these last fifty years. I say that the forenamed kings, especially the Spainards and Portugalls, have ships of great bulke, but fitter for the merchant than the man of warre, for burthen then for battaile. . . . . Although we have not at this time 135 ships belonging to the subjects of 500 tuns each ship, as it is said we had in the 24th yeare of Queen Elizabeth, at which time also, upon a generall view and muster, there were found in England, of all men fit to beare arms, eleaven hundred and seventy-two thousand; yet are our merchants' ships now farre more warlike and better appointed than they were, and the royal navy double as strong as then it was. . . . . We have not, therefore, lesse force than we had, the fashion and furnishing of our ships considered; for there are in England at this time 400 saile of merchants fit for the wars, which the Spainards would call gallions; to which we may add 200 saile of crumsters or hoyes, of Newcastle, which each of them will beare six demi-culverins, and four sakers, needing no other addition of building than a slight spar-decke fore and afte, as the seamen call it, which is a slight decke throughout. The 200 which may be chosen out of 400, by reason of their ready staying and turning, by reason of their windwardnesse, and by reason of their drawing of little water, and they are of extreame vantage neere the shoare, and in all bayes and rivers to turn in and out; these, I say, alone, well manned and well conducted, would trouble the greatest prince in Europe to encounter in our seas; for they stay and turn so readily as, ordering them into small squadrons, three of them at once may give their broad-sides upon any one great ship, or upon any angle or side of an enemy's fleet. They shall be able to continue a perpetuall volley of demi-culverins without intermission, and either sink or slaughter the men, or utterly disorder any fleete of crosse sailes with which they encounter.

"I say, then, if a vanguard be ordained of these hoyes, who will easily recover the wind of any other ships, with a battaile of 400 other warlike ships, and a reare of thirty of his majestie's ships to sustaine, relieve, and countenance the rest (if God beat them not), I know not what strength can be gathered in all Europe to beat them. And if it be objected that the states can furnish a farre greater number, I answer, that his majestie's forty ships, added to 600 before named, are of incomparable greater force than all that Holland and Zeeland can furnish for wars."

Ships of royal navy inferior to merchant-ships.

In the foregoing extract there is strong evidence that the ships of the royal navy were generally inferior to those employed by the merchant-service, in the essential qualifications of being weatherly. This is exactly the conclusion that might be arrived at from the consideration, that a private individual would dispense with all that superabundance of top-hamper which was entailed on the ships of the royal navy, by the accommodation required for the numerous officers and gentlemen generally embarked on board them, and also by the mania for gorgeous decorations. This mania is well exemplified by the fact, that of the Sovereign of the Seas it is stated, "She beareth five lanthornes, the biggest of which will hold ten persons to stand upright, and without shouldering one another."

Sir Walter Raleigh, in his *Discourse on the Royal Navy and Sea-Service*, adverts to the same subject. He says, "We find by experience, that the greatest ships are lesse serviceable, goe very deep to water, and of marvellous charge and fearefull cumber, our channells decaying every yeare. Besides, they are lesse nimble, lesse maineable, and very seldome imployed. *Grande navio, grande fatica*, saith the Spainard; a ship of 600 tons will carry as good ordnance as a ship of 1200 tons; and though the greater have double the number, the lesser will turn her broad-sides twice before the greater can wend once; and so no advantage in that overplus of ordnance. And in the building of all ships, these six things are principally required:—1. First, that she be strong built; 2. Secondly, that she be swift; 3. Thirdly, that she be stout sided; 4. Fourthly, that she carry out her guns all weather; 5. Fifthly, that she hull and try well, which we call a good sea ship; 6. Sixthly, that she stay well when bourding and turning on a wind is required.

History.

"1. To make her strong, consisteth in the truth of the workeman and the care of the officers.

"2. To make her sayle well, is to give a long run forward, and so afterward done by art and just proportion. For, as in laying out of her bows before, and quarters behind, she neither sinck into nor hang in the water, but lye cleare off and above it; and that the shipwrights be not deceived herein (as for the most part they have ever been), they must be sure that the ship sinck no deeper into the water than they promise, for otherwise the bow and quarter will utterly spoile her sayling.

"3. That she be stout, the same is provided and performed by a long bearing floore, and by sharing off above water even from the lower edge of the ports.

"4. To carry out her ordnance all weather, this long bearing floore, and sharing off from above the ports, is a chiefe cause, provided alwayes that your lowest tyre of ordnance must lye foure foot cleare above water when all loading is in, or else those your best pieces will be of small use at the same in any growne weather that makes the billoe to rise, for then you shall be enforced to take in all your lower ports, or else hazard the ship.

"5. To make her a good sea ship, that is to hull and trye well, there are two things specially to be observed; the one that she have a good draught of water, the other that she be not overcharged, which commonly the king's ships are, and therefore in them we are forced to lye at trye with our maine course and missen, which, with a deep keel and standing streake, she will performe.

"6. The hinderance to stay well is the extreame length of a ship, especially if she be floaty and want sharpnesse of way forwards; and it is most true, that those over-long ships are fitter for our seas than for the ocean; but one hundred foot long, and five and thirty foot broad, is a good proportion for a great ship. It is a speciall observation, that all ships sharpe before, that want a long floore, will fall roughly into the sea, and take in water over head and ears.

"So will all narrow quartered ships sinck after the tayle. The high charging of ships is it that brings them all ill qualities, makes them extreame leeward, makes them sinck deep into the water, makes them labour, and makes them overset. Men may not expect the ease of many cabbins, and safety at once, in sea-service. Two decks and a half is sufficient to yield shelter and lodging for men and mariners, aud no more charging at all higher, but only one low cabbin for the master. But our marriners will say, that a ship will beare more charging aloft for cabbins, and that is true, if none but ordinary marryners were to serve in them, who are able to endure, and are used to, the tumbling and rowling of ships from side to side when the sea is never so little growne; but men of better sort and better breeding would be glad to find more steadinesse and lesse tottering cadge-work. And albeit, the marriners doe covet store of cabbins, yet indeed they are but sluttish dens, that bread sicknesse in peace, serving to cover stealths, and in fight are dangerous to teare men with their splinters."

Fuller's Worthies.

In Fuller's *Worthies*, there is also a short summary of the comparative qualities of the ships of different nations in the middle of the seventeenth century. It is as follows: "First, for the Portugal, his cavils and carracts, whereof few now remain (the charges of maintaining them far exceeding the profit they bring in); they were the veriest drones on the sea, the rather because formerly their seeling was dam'd up with a certain kind of mortar to dead the shot, a fashion now by them disused.

History.

"The French, however dexterous in land-battles, are left-handed in sea-fights, whose best ships are of Dutch building. The Dutch build their ships so floaty and buoyant, they have little hold in the water in comparison to ours, which keep the better winde, and so outsail them.

"The Spanish pride hath infected their ships with loftiness, which makes them but the fairer markes to our shot. Besides the winde hath so much power of them in bad weather, so that it drives them two leagues for one of ours to the leeward, which is very dangerous upon a lee-shore.

"Indeed the Turkish frigots, especially some thirty-six of Algier, formed and built much nearer the English mode, and manned by renegadoes, many of them English, being already too nimble heel'd for the Dutch, may hereafter prove mischievous to us, if not seasonably prevented."

Rise of Dutch naval power.

During the early part of the seventeenth century, the Dutch navy rapidly increased in importance. Their success in having wrested from the Portuguese a share of the commerce of the east, emboldened them, in the then depressed state of the Spanish marine, to make a similar attempt on the west, and endeavour to establish settlements in South America.

The wars with Spain, in which they were consequently engaged, had such an important effect in establishing their maritime power, that in 1650 their navy consisted of 120 vessels fitted for war, seventy of which had two tiers of guns; and their fleet was in all respects the most efficient in Europe.

Evelyn's *Navigation and Commerce.*

Evelyn, in his tract on Navigation and Commerce, speaking of the fisheries, says "Holland and Zeeland alone should, from a few despicable boats, be able to set forth above 20,000 vessels of all sorts, fit for the rude seas, of which more than 7000 are yearly employed upon this occasion. 'Tis evident that by this particular trade they are able to breed above 40,000 fishermen and 116,000 mariners, as the census (1639) has been accurately calculated."

The tremendous struggle in which they were enabled by these means to engage with us shortly after this period, in consequence of the injurious operation of the navigation act on their commerce, had a most influential effect on the improvement of our navy, which at the commencement of the contest was very unequal to that of the Dutch; and it is probable that this war was the means of enabling us to contend triumphantly against the immense and unexpected attempts of Louis XIV. to wrest the sceptre of the seas from our grasp.

Charles I.

The sovereigns of the house of Stuart, without exception, appear to have devoted much attention to the improvement of the navy. Charles I. may be almost said to have lost both crown and life in consequence of these efforts; nor would it be doing justice to Cromwell to omit mention of the energy with which he took advantage of the all but despotic power which he possessed to increase his naval force. For this purpose not only many ships were built during the protectorate, but numbers of merchant-vessels were bought for the service of the state.

Charles II. His personal attention to ship-building and naval affairs.

After the Restoration, Charles II. paid great personal attention even to the minutiæ of his navy, as shown by the following curious extract from a letter of his to Prince Rupert, preserved in the state-papers, and also by continual references to his naval predilections in Evelyn's and Pepys's memoirs and writings. The letter is dated 4th August 1673. It says, "I am very glad the Charles does so well; a gerdeling this winter when she comes in will make her the best ship in England; next summer, I believe, if you try the two sloops that were builte at Woolidge that have my invention in them, they will outsail any of the French sloops. Sir Samuel Mooreland has now another fancy about weighing anchors; and the resident of Venice has made a model also to the same purpose. We have not yet consulted them with Mr Tippet nor Mr Deane; but hope when they are well considered, we may find one out of them that will be good."

Sir Anthony Deane.

In Pepys's *Diary*, 19th May 1666, there is the following notice relating to one of the gentlemen mentioned in the above letter:—"Mr Deane and I did discourse about his ship the Rupert, which succeeds so well, as he has got great honor by it, and I some by recommending him. The king, duke, and everybody, say it is the best ship that was ever built. And then he fell to explain to me his manner of casting the draught of water which a ship will draw beforehand, which is a secret the king and all admire in him; and he is the first that hath come to any certainty beforehand of foretelling the draught of water of a ship before she be launched." This gentleman appears therefore to have been the first who applied mathematical science to naval architecture in this country. Pepys also says, "another great step and improvement to our navy, put in practice by Sir Anthony Deane," was effected in the Warspight and Defiance, which were "to carry six months' provisions, and their guns to lie $4\frac{1}{2}$ feet from the water." This was in 1665.

First application of mathematical calculation to naval architecture.

The foregoing extract probably indicates the date of the first practical application to a useful purpose in this country of the famous discovery of Archimedes. It is well known that he was called upon by his king to test the purity or the adulteration of the gold of the royal crown, and the displacement of the water of his bath by his own immersion therein suggested to his mind the means of solving the problem. He saw that a body immersed in water displaced its own bulk of water, and after this the knowledge followed that a body floating in a fluid displaced its own weight of that fluid. If the weight of the body, therefore, was known, the quantity of water which it would displace could immediately be calculated, and the depth to which it would sink be found.

Sir Robert Slingeby.

In this historical sketch the probability that the merchant-shipping of England were superior in their sea-going qualities to those composing the royal navy, has been adverted to in a *Discourse touching the Past and Present State of the Navy*, by Sir Robert Slingeby, knight-baronet, and comptroller of the navy, dated 1669, there is the following interesting statement, which points to a reason why this superiority of the merchant-shipping may have existed. "But since these late distractions began at home" (the Commonwealth), "forraigne trade decayed, and merchants so discouraged from building, that there hath been scarce one good merchant-ship built these twenty years past, and of what were then in being, either by decayes or accident, there are very few or none remaining. The merchants have found their private conveniences in being convoyed att the publick charge; they take noe care of making defence for themselves if a warr should happen." Yet he says, in the time of Charles I., "the merchants continued their trade during the wars with France and Spain, if there could but two or three consort together, not caring who they met," they being little inferior in strength or burthen to the ships of the royal navy.

Decay of mercantile navy during the Commonwealth.

Its subsequent improvement.

Sir Richard Haddock.

First analysis of the royal navy.

About 1684 Sir Richard Haddock, comptroller of the navy, adopted the recommendation of Mr, afterwards Sir Anthony Deane, at that time surveyor of the navy, and directed an inquiry to be made as to "the number of cube feet that are contained in the bodyes of several draughts to their main water-line, when all materialls are on board fitt for saileing." The result of this inquiry was a very voluminous statement of the weights which made up the whole displacement of the fourth, fifth, and sixth rate ships, including minute details of their masts, yards, armament, &c., accompanied by perfect drawings of each ship. The following table contains the dimensions and displacements, &c., of each class:—

Table of Dimensions, from a Manuscript dated 1684.

James II.

James II., from having so long and so gloriously filled the office of Lord High Admiral while Duke of York, was perfectly aware of the requirements of the navy; and during his short reign he paid great attention to increasing its efficiency. He also especially directed inquiries into the question of the durability of timber for the construction of it, and carefully accumulated both materials and stores for its maintenance. It is not a little curious that it was probably the attention which the monarchs of the line of Stuart had bestowed on the naval service, which enabled it so triumphantly to resist the persevering attempts of Louis XIV. to recover for them the throne of their ancestors.

The Revolution.

Though England was at the Revolution possessed of an efficient fleet, manned by experienced seamen, who had all the confidence arising from a series of naval triumphs, it must be remembered that for a long period no opposition to her naval superiority had been anticipated from any other power than Holland; and consequently the fleets of England were composed of ships which had many of them been built to adapt them to this service, for which small dimensions and light draughts of water were essential qualifications, on account of the shoalness of the Dutch coast.

William III.

William was too cautious a monarch to have neglected so important a means of national defence as was the navy, when engaged with such an ambitious and energetic opponent as Louis XIV.; and we find that the naval force was considerably increased, both numerically and in dimensions, during his reign. But the triumphs of our armies under Marlborough having for a time diverted the attention of the nation from naval affairs, it fell into decay during the reign of his successor.

Louis XIV.

When Louis XIV. determined to dispute with England the sovereignty of the seas, he was not only without a navy, but without the means of forming one. The military and commercial marine of France had ceased to exist. The sanguine temperament of the monarch, and the wisdom of his minister Colbert, removed all obstacles; commerce began to flourish on the quays, merchant-vessels to crowd the ports; dockyards, harbours, and shipping appeared simultaneously to start into existence; and the nation, which almost for centuries had been essentially military, felt constrained to turn its energies to commerce and to the sea. A navy which, in 1661, consisted of some four or five small vessels, in little more than ten years bearded and baffled the combined fleets of Holland and of Spain, and asserted the sovereignty of the Mediterranean. In 1681 her fleets consisted of 115 line-of-battle ships, manned by 36,440 men, with 179 smaller ships, the crews of which amounted to 3037 men; and in 1690 a fleet of eighty-four vessels of war, out of which three were of a hundred guns and upwards, and ten others were above eighty-four guns, with twenty-two fire ships, was cruising in the British seas. It is true that these mighty armaments failed in fulfilling the ambitious designs of Louis. But the severity of the struggle, which at length ended in the annihilation of his hopes, and in our triumphant assertion of our naval superiority, must always serve as an example of the danger we may incur by too great confidence in that superiority.

Rise of French naval power.

Comparison between English and French ships.

The following comparison between the French and British ships of about this period, is from an official contemporary paper, by a gentleman of the name of Gibson:—"Our guns being for the most part shorter, are made to carry more shott than a French gunn of like weight, therefore the French guns reach further, and ours make a bigger hole. By this the French has the advantage to fight at a distance and wee yard-arm to yard-arm. The like advantage wee have over them in shipping; although they are broader and carry a better saile, our sides are thicker, and better able to receive their shott; by this they are more subject to be sunk by gunn shott than wee."

Injudicious management of royal navy.

The paper also complains much of the injudicious management of our shipping, by which it says, "many a fast sayling shipp have come to loose that property, by being over-masted, over-rigged, over-gunned (as the Constant Warwick, from twenty-six gunns, and an incomparable sayler, to forty-six gunns and a slugg), over-manned (vide all the old shipps built in the parliament time now left),

History.

over-built (*vide* the Ruby and Assurance), and haveing great tafferills, gallarys, &c., to the making many formerly a stiff, now a tender-sided shipp, bringing thereby their head and tuck to lye too low in the water, and by it takeing away their former good property, in steering, sayling, &c. The French by this defect of ours make war with the sword (by sending no small shipps of warr to sea, but clean), and wee, by cruseing in fleetes, or single shipps foule, with bare threates."

Lord Rodney.

In a letter from Sir George (afterwards Lord) Rodney, dated the 31st May 1780, to Mr Stephens, the secretary of the Admiralty, is a passage which goes to prove the truth of the above statement. "Nothing could induce them (the French fleet) to risk a general action, though it was in their power daily. They made, at different times, motions which indicated a desire of engaging, but their resolution failed them when they drew near; and as they sailed far better than his majesty's fleet, they with ease could gain what distance they pleased to windward."

Cause of inferiority of English ships.

One great cause of the inferiority of our ships arose from the practice which prevailed during the first half of the eighteenth century, through a mistaken idea of economy, of "rebuilding" old ships, without reference to the opinions of practical men, so that the forms and dimensions of the previous century passed down, in many instances, into the succeeding one, and justice was not done to the ship-building knowledge of the surveyors.

French system followed by Spain.

The French system of improvement was followed by the Spaniards, and the capture of the Princessa, in 1740, of 70 guns, 165 feet in length, and 49 feet 8 inches in breadth, when our ships of the same force then building were only 151 feet long and 43 feet 6 inches broad, caused an appeal to be made by the Admiralty to Admiral Sir John Norris. The surveyors of the navy of that date who had succeeded Sir A. Deane were men of no note, because no opportunity of showing their powers had been allowed them. In consequence of the inquiries then made, the several master-shipwrights of the dockyards were directed to send in proposals for the future established dimensions of the navy; and, in 1745, Sir Jacob Attwood being surveyor of the navy, the Admiralty issued a new establishment for the dimensions of the several ratings of ships. The following table, taken from Derrick's *Memoirs of the Royal Navy*, contains the various established alterations from time to time, from the reign of Charles II. to this of 1745, which was the last:—

Improvements attempted by the Admiralty.

History.

The ships built after the establishment of 1745 are reported to have been stiff, and to have carried their guns well, but were still inferior to those of the French; and, consequently, about ten years afterwards an alteration was made in the draughts for the several ratings, and the dimensions were also slightly increased. It may not be uninteresting to remark, that the proportional breadths in the establishment of 1745 considerably exceeded those of more modern ships. Their length varied from 3·49 to 3·85 of their breadth; while the lengths of most of our line-of-battle ships, built shortly afterwards, are within the limits of 3·61 and 3·83 of their breadths.

Royal George.

The Royal George was the first ship built on the increased dimensions, which were the result of the before-mentioned inquiry. She was laid down in 1746, and launched in 1756; and rather more than ten years afterwards, that is, in 1758, Thomas Slade and William Bateley being the surveyors of the navy, the Triumph and Valiant of 74 guns were built on the lines of the Invincible, a French 74 gun-ship, captured in 1747.

Triumph and Valiant.

The dimensions of these ships are given below, as they were manifestations of an improved system, which, however, was not persevered in; for, with the exception of occasionally building after a French or Spanish model, the English ships were scarcely altered from those built at the commencement of the century.

	Royal George.	Triumph and Valiant.
	Feet. In.	Feet. In.
Length on the gun-deck	178 0	171 3
Length of the keel, for tonnage	143 5½	138 8

Depth in hold	21 6	21 3
Burthen in tons	2047	1826

History

There was still a very essential distinction between the navy of England and of either France or Spain, which was this, that until after 1763 neither of these nations had any three-deckers in their fleets. Their largest armament appears to have been eighty-four guns on two decks, while we had third-rates which were three-deckers, as the Cambridge and Princess Amelia, launched in 1754 and 1757, and carrying only eighty-four guns, our naval officers of that period having advocated a high battery, and the naval architects having designed some very fine ships of this new class. The capture of the Foudroyant, a French eighty-four on two decks, in 1758, caused a change in this respect, by furnishing the English with a model for a very superior class of men-of-war, which was adopted. Derrick, in his *Memoirs of the Royal Navy*, says, that "no eighty-gun ship with three decks was built after the year 1757, no seventy-gun ship after 1766, nor any sixty-gun ship after 1759."

Grand distinction between English and foreign navies.

During the peace that preceded the war with America, which commenced in the year 1768, the French had introduced three-deckers into their fleets, having found their eighty-fours on two decks to be no match for the more powerful of our three-deckers. Their first-rates were at this time generally of 110 guns on three decks. The Bretagne, one of these ships, was, according to Charnock, 196 feet 3 inches long on the water-line; and her moulded breadth was 53 feet 4 inches. Her displacement, it is stated in Sewell's *Collection of Papers on Naval Architecture*, was 4640 English tons.

French-built three-deckers.

In 1786 the establishment of the French fleet was fixed by an ordinance of the government, as according to the following table, which is extracted from Charnock, and some very fine vessels of each class were built upon these dimensions:—

Establishment of French fleets.

	Ships of 120 Guns.	Ships of 110 Guns.	Ships of 80 Guns.	Ships of 74 Guns.	Ships of 64 Guns.	Frigates carrying 18 Pounders.	Frigates carrying 12 Pounders.	Corvettes of 20 Guns.	Advice-boats, carrying four 4 Pounders.

George III. and George IV.

The ships of England continued throughout the wars of the reign of George III. inferior to those of France and Spain. The skill of our commanders, and the indomitable courage of our seamen, eventually succeeded in these, as in all former contests, in annihilating opposition, and in triumphantly asserting our naval supremacy. It cannot be denied that their task would have been comparatively easy, accompanied with less loss of life and expenditure of treasure, had their ships been more upon a par with those of their opponents. The French officers, however, after the war, to save their vanity, attributed our successes at sea to the superiority of our ships, and they commenced building after our models.

Although so much attention appears to have been directed at various times to the improvement of the navy, not only by the servants of the crown officially connected with it, but by the sovereigns themselves, we have seen that an inferiority of our ships in sailing to those of our opponents has been repeatedly asserted on undoubted testimony. The reason that all the attention thus bestowed failed in producing a corresponding beneficial effect appears to have been that in England the speculative ideas of men, undoubtedly of sense and judgment, as may be seen from the quotations of their opinions which have been given, but men uninformed as to principles, were taken as the rules for guidance. In France, on the contrary, the aid of science was called in, and some of the greatest mathematicians of the time turned their attention to the improvement of the shipping of that country, and worked harmoniously with the naval officers who were to use the ships, as

Reasons for the continued inferiority of British shipping.

History.

well as with the practical men who were to construct them, modifying their theories by the practice and experience of the others. Colbert employed an engineer of the name of Rénau d'Elisagary, a protégé of the Count de Vermandois, whose first essay was in the adaptation of ships to carry bombs, to be used in the then projected armament against the piratical states of the Mediterranean. Under the enlightened direction of Colbert, the French ships which, by the ordinance of 1688, were much restricted in dimensions, were increased nearly one-fourth in size, and every means taken which the then state of knowledge could suggest to insure a proportionate improvement in their qualities; while a corresponding increase in size was not made in English ships till the commencement of the energetic surveyorship of Sir William Symonds in 1830. Rénau was, we believe, the first French author who wrote on the theory of ships. He was followed by the Bernoullis, by Père La Hoste, by Bouguer, Euler, Don Jorje Juan, Romme, and a host of others, the effects of whose writings may be traced in the progress of the improvements introduced into the navies of France and Spain, and which the navy of England was forced to imitate. The only English treatise of that period on ship-building that can lay any claim to a scientific character was published by Mungo Murray in 1754; and he, though his conduct was irreproachable, lived and died a working shipwright in Deptford dock-yard.

Instance of ignorance.

A palpable instance of the ignorance or neglect of all the principles of naval architecture among the authorities who were charged with designing our royal navy, even up to the close of the last century, may be quoted from an article in the Papers on Naval Architecture, as given by Mr Wilson then of the Admiralty.

Razee of the Anson.

Mr Wilson, speaking of the cutting down of the Anson, a sixty-four-gun ship, to a frigate of thirty-eight guns, says, "she was cut down in the year 1794; and although in all other maritime states the science of naval construction was well understood, yet so culpably ignorant were the English constructors, that this operation, so well calculated, when properly conducted, to produce a good ship, was a complete failure. Seven feet of the upper part of the top sides, together with a deck and guns, making about 160 tons, were removed, by which her stability was greatly increased; but, by a complete absurdity, the sails were reduced one-sixth in area. In her first voyage the rolling was so excessive that she sprung several sets of top-masts. To mitigate this evil, in 1795, her masts and yards were increased to their original size; but as there were no decrease of ballast, she was still a very uneasy ship, and, as a necessary result, her wear and tear were excessive.

"Other sixty-fours were cut down, masted, and ballasted in exactly the same manner, and, it need scarcely be added, experienced similar misfortunes; and although they were improved by enlarging their masts and yards, they were still bad ships. Had their transformations been scientifically conducted, a class of frigates would have been continued in the navy, capable, from their size, of coping with the large American frigates; and thus the disasters we experienced in the late war, from the superior force of that nation, would, without doubt, have been not merely avoided, but turned into occurrences of a quite opposite character."

Improvements in naval architecture in this country.

The subject, however, of the improvement of ship-building was by no means lost sight of in this country at that period. The investigations and experiments which were made were, as usual in England in comparison with France and other continental nations, more of a practical than of a theoretical nature. Attwood's papers, read before the Royal Society in 1796 and 1798, form almost a solitary exception to this remark. In 1785, and subsequent years, Mr Miller of Dalswinton, in Dumfriesshire, made many experiments, expending as much as L.30,000 of his own private fortune for the advancement of naval architecture. In 1788 he was induced, by a Mr Taylor, to allow Symington, a working-engineer, to place a steam-engine on board a pleasure-boat on his lake at Dalswinton, for the purpose of propelling it by a paddle-wheel, and he thus became the originator of steam-navigation.[1]

Beaufoy's experiments.

In 1791, "a Society for the Improvement of Naval Architecture" was instituted, mainly by the exertions of Colonel Beaufoy. This society numbered amongst its members the then Duke of Clarence, afterwards William IV., and many noblemen and gentlemen of great influence. They conducted a most valuable series of experiments between 1793 and 1798, but a first report only of the results was ever published by the society. The funds at their disposal became exhausted, and the experiments were thus terminated, the interest of the public having flagged on account of the necessarily tedious nature of the proceedings. A detailed account of the whole of the experiments was subsequently published, in a most patriotic spirit, by Mr Henry Beaufoy, at his own private expense, and presented gratuitously to scientific societies and parties connected with naval architecture. Some valuable practical results were deduced from them, and these will be discussed hereafter, when treating of the resistances and other qualities of differently formed vessels.

Increase of merchant-shipping.

At the commencement of the present century the merchant-shipping of this country had increased to such an extent as to be of great importance. From the returns prepared by the Registrar-General of the Board of Trade, the total number of British merchant-vessels in the year 1801 was 19,711, with an aggregate registered tonnage of 2,038,253 tons, employing 149,766 men. In 1811 the total number of merchant-vessels was 24,106, with an aggregate registered tonnage of 2,474,784 tons, employing 162,547 men.

East India Company's shipping.

In the Honourable East India Company's service there were at this period 67 ships, each carrying 30 to 38 guns, 31 ships of 20 to 28 guns, and 52 ships of 10 to 19 guns, thus forming a powerful addition to the warlike resources of the country. Additional attention was also attracted to the subject of ship-building in the early part of this century by the institution of the Royal Yacht Club. It was joined by many influential and wealthy noblemen and gentlemen, and they gave much encouragement to the production of superior fast-sailing yachts.

School of Naval Architecture at Portsmouth.

Another important effort to improve the scientific knowledge of naval architecture, was the establishment, in 1811, of a school for naval architecture in Her Majesty's Dockyard at Portsmouth. This school was the result of the statements and recommendations contained in the report of a commission of naval revision, appointed in 1806, to examine into the management of the dockyards. The commissioners found that the practice of permitting the master shipwrights and their assistants to take private apprentices, receiving high fees with them, had been at that time disallowed and discontinued. By this system young men of superior early education, and of superior standing to the ordinary shipwright apprentices, had been trained in the higher branches of the profession, and their further scientific and theoretical education had been attended to, while at the same time they had acquired a knowledge of practical shipbuilding by being employed amongst the workmen. The commissioners therefore considered it expedient that some means should be adopted to supply the future demand for such men to fill those higher civil situations in which scientific knowledge is indispensable for the due performance of the duties. The school was accordingly instituted, but upon

[1] *Sketch of the Origin and Progress of Steam Navigation*, Bennet Woodcroft, 1848.

so large a scale, and with so little consideration of the real requirements of the service, that in a very few years 42 students were educated there, while the whole number of places in the Admiralty service, requiring such education and training, did not exceed 25 or 26. The necessary result of this was, that they were put into inferior positions for which their previous standing and training had not adapted them, and the school was considered to have been a failure. Much increase, however, of sound scientific knowledge resulted from the labours of the principal of the school, the late Dr Inman, though it may be remarked that he confined his labours to too limited a sphere, and did not follow out the investigations of the French mathematicians. Many valuable papers on naval architecture have also been published by different members of the school, and the article Ship-building, in the previous edition of this work, and from which much of the present article is taken, was written by the late Mr Creuze, one of its most talented and distinguished members.

The following table, taken from the navy list of 1813, will show the force of the royal navy at that period, distinguishing the number of ships in each class:—

Extent and Disposition of the British Naval Force in 1813.

In 1832 the Navy Board was abolished, and it was determined to place the construction of ships under one head, continuing the name of surveyor of the navy, but altering the nature of the office by the appointment of a naval officer instead of a naval architect and ship-builder. Captain (afterwards Rear-Admiral Sir) William Symonds was the officer selected. He had early distinguished himself amongst his brother-officers by the attention he had paid to the sailing properties of boats and vessels. It was said of him that he could take any one of the boats in turn, of the vessel to which he was attached, and make her beat any of the others. His habit of observing the peculiarities of the different ships, whose properties he had an opportunity of witnessing, led him to draw certain conclusions respecting the forms of vessels; and, while holding a civil appointment in Malta, he built a yacht called the Nancy Dawson, in accordance with these preconceived views. The great speed of this yacht gained him notoriety, and procured for him the patronage and support of several influential and patriotic noblemen. Through their influence he obtained the sanction of the Board of Admiralty to build a corvette, the Columbine, and as this vessel was very favourably reported of, his character as a designer was proportionally raised. These successes led to his appointment as surveyor of the navy. It is not proposed here to discuss the propriety or otherwise of this office being filled by a naval officer, though in Sir William Symonds' case it led to important changes in the construction of the ships of the royal navy, and to much acrimony of feeling on the part of the shipwright officers of the service. One point is quite certain, that no man can be qualified to control the different forms of the various classes of ships, more especially of new classes that may be required in the navy, without long and careful study of the subject of naval architecture, both practically and theoretically. It is equally certain that a naval officer of experience is the most competent judge of the general proportions and qualities of the ships that will be most useful in the service, and that he is best able to point out the faults at sea of any ships that have been tested, so as to lead to the correction of these faults, and the improvement of future ships.

Sir William Symonds was the first constructor of the English navy who was left unrestricted as to dimensions, and he was consequently enabled to introduce into the service ships which undoubtedly bear very high characters as men-of-war. He also practically demonstrated the possibility of ships of war obtaining sufficient stability without the aid of ballast—a very important advantage, and one which has been productive of much benefit. He was in error, however, as to the true principles on which the stability of floating bodies is dependent, in order to secure as great freedom from rolling and as great ease of motion as possible. His ships had great statical stability, and therefore great power of carrying sail, and hence were generally very successful in trials of speed in sailing. But this advantage was not obtained without, in many instances, incurring a compensating disadvantage from uneasiness of motion. This appears to have been a very general fault in ships of his construction, some of them being marked examples of the uneasiness attendant on a stability which depends almost wholly on breadth at the load-water section and above it, to the neglect of the form of the solids of

immersion and emersion. His ships, however, were very general favourites in the service amongst the officers in command of them, who in their reports made light of any faults, and bore any personal inconvenience and want of comfort cheerfully and willingly, on account of the speed of their ships and their success in the sailing matches. The country is much indebted to Sir William Symonds for many improvements which he introduced into the navy, especially at the commencement of his tenure of office. He failed, however, to keep pace with the improvements of his time, his want of scientific education and of enlarged views rendering him unable to go beyond or apply to steamers, or any new class of vessels, the ideas which he had imbibed in his earlier years, and to which he adhered with a pertinacity amounting to obstinacy.

The following table contains the dimensions of the various classes of ships which Sir William Symonds introduced into the British navy, as well as of one or two other English ships built to compete with those of his construction. The dimensions according to which the ships of the French navy were at that time built are also given:—

Dimensions of English Ships of War at the period when Sir W. Symonds was Surveyor of the Navy.

The introduction of vessels propelled by steam for practical purposes dates its origin in the year 1812, when Henry Bell started the Comet steam-vessel on the Clyde, for the conveyance of passengers. In 1815 there were 10 steamers in existence, with an aggregate registered tonnage of 1633 tons. In 1825 this number had increased to 168, with an aggregate tonnage of 20,287 tons, and in 1835 the number was 538, with an aggregate tonnage of 80,520. Some interesting and valuable experiments were made about 1832, by Mr Scott Russell, on the Forth and Clyde Canal, with a view to introduce steam on canals, and though not successful in their object, a peculiar class of very long and finely-formed boats for quick passenger traffic on canals resulted from them. These boats were drawn by two horses, and were expected to travel at the rate of 9 or 10 miles per hour, but it was found that if these were not at once put to this speed, but started sluggishly or gradually, a wave was formed in front of the boat and continued to precede it, washing over the banks of the canal and over the towing-path. Under these circumstances the horses were much distressed with the labour which they had to perform. If, on the other hand, they were urged into a speed of 9 or 10 miles an hour at once upon starting, no wave was formed, and the boat seemed to rise on the surface of the water and to be propelled with comparative ease so long as that speed was maintained; but if they flagged, and their rate of travelling fell to 6 or 7 miles an hour, the wave was formed, and it then became necessary to go slower, or walk

History. them till it disappeared, and then to start them again at once into the higher speed. This peculiar result was no doubt mainly caused by the confined space of the canal, but no scientific investigation to account for it has yet been given. The lines of these boats were called wave-lines by Mr Scott Russell, and for ease of propulsion in smooth water they are undoubtedly beneficial. Lines of a similar character were also used about the same time by Mr Fearnall in fast-passenger steamers on the Thames. Their advantage was made very apparent by the construction of the Vesper in 1837, a passenger-boat from London Bridge to Gravesend. This boat went through the water at a speed of about 12 miles an hour, with scarcely any wave or even a ripple at her bows, while her competitors were carrying a heavy wave and swell before them. Other vessels with lines of a similar character were built subsequently by Messrs Fletcher and Fearnall, by Mr Ditchburn, who had been in their employment, and also by others.

Up to 1836 the mercantile marine had laboured under the disadvantage of a tonnage law for the charging of dues, which, by the mode of measurement enacted, held out a premium for the construction of inferior ships. In this year a new act was passed, and a better system introduced. By this act the internal capacity of a ship became the measure of her tonnage, and the serious objections to the former law were obviated.

It was about this period that iron began to be used to any great extent as a material for ship-building. Its merits for this purpose will be discussed hereafter, when treating of the practical construction of ships. Mr Manby, Mr Laird of Liverpool, and Mr Fairbairn of Manchester, were the first constructors of vessels of any size of this material. Mr Fairbairn, in 1833 and 1834, built two passenger-steamers of iron to ply on the Humber, between Selby and Hull, and in 1836 he commenced business in company with others as an iron-ship-builder at Millwall, on the Thames. In 1837 Mr Laird built an iron steam-vessel, the Rainbow, for the General Steam Navigation Company at Deptford, and from that time the use of iron has rapidly increased.

The next important step in the history of ship-building was the introduction of the screw-propeller. Many proposals had been made, and patents taken out, for propellers of this nature; but a small vessel fitted with a propeller, patented by Ericsson, was the first brought into practical use. A small experimental vessel called the F. B. Ogdon, was built in 1837, and fitted by Ericsson with one of his propellers, and the Lords Commissioners of the Admiralty, attended by their secretary, Sir William Symonds, took a trip in her in that year. They, however, failed to see the advantage of such an invention to men-of-war, and refused to entertain any proposal for its introduction into the navy. Mr F. P. Smith also built a small experimental vessel during this year, and fitted her with a screw propeller. Ericsson, on receiving no encouragement from the British government, took steps to bring his invention before the Americans, and a small vessel, the Robert F. Stockton, was built by him in 1838, in this country, with this view, and made the voyage safely to America. Mr Smith, in the meantime, induced a number of influential men to form a company to carry out his invention, and in 1839 the Archimedes was built by them, to test and demonstrate its value. The success of this vessel was such, and the advantages likely to accrue to men-of-war from the introduction of the screw were so apparent, that the Rattler was then ordered to be built in one of the government yards. This vessel was on the same lines as one of the Admiralty paddle-wheel steamers, but its stern was lengthened to fit it to receive the screw propeller. Her success was undeniable, but the progress of the screw in the navy was very slow for many years, owing to the opposition of Sir William Symonds and to the frequent changes of the Board of Admiralty. Some progress, however, was made in the introduction of screw-ships into the navy, several small vessels being built to the designs of Mr Fincham, the master shipwright of Portsmouth yard. This officer was in favour of its introduction, as were all the officers of the engineering department under the Board of Admiralty, and they were supported by the Hon. Mr Corry, the secretary of the Admiralty at that time. The Arrogant and Dauntless, two screw-frigates, were afterwards built by Mr Fincham; and, at the same time, the Termagant, also a screw-frigate, was built by Mr White of Cowes. After this, the growing dissatisfaction with the excessive rolling of Sir William Symonds' ships, his obstinate adherence to his own forms of construction, together with his unwillingness to co-operate in the introduction of screw-steam ships into the navy, led the Board of Admiralty, of that date, to order that a committee of reference should be constituted, to whom all designs for ships should be submitted before they were laid down. This led to Sir William Symonds resigning his office, and Sir Baldwin Walker, the present surveyor, was appointed as his successor. It was understood that Sir Baldwin Walker had not given his attention to the study of naval architecture in all its branches, and the Board of Admiralty announced that they should not expect him to originate the lines of the vessels to be built, but that these should be designed by naval architects attached to his office. The construction of the ships of the royal navy was thus placed on a proper footing, and if this arrangement be carried out, and the naval architects have full power given to them, and be at the same time competent men, the country ought to reap the benefit of so judicious an arrangement. History.

With respect to the class of ships ordered to be built at this period in the dockyards no change in accordance with the advancing state of screw propulsion took place. The naval members of the Board of Admiralty were men who had long looked upon the noble line of battle-ships of the navy as not to be surpassed, and they could not apparently make up their minds to desecrate them, as they seemed to consider it, by the introduction of steam-power. The result of this somewhat romantic feeling was, that early in Sir Baldwin Walker's administration a number of sailing three-deckers were laid down in opposition to the expressed opinion of the leading civil professional officers attached to the admiralty. Not one of these vessels has been launched, or will be launched, as a sailing vessel. They have all been converted, or are under conversion, to screw-ships, by being lengthened in midships, at the bows and also at the sterns. The greater proportion of the other sailing three-deckers are also being razéed and converted into two-decked screw-ships, their sterns only being altered. These important changes on the last-mentioned vessels are being carried out, while two of the members of the late school of naval architecture are the assistant-surveyors; and a repetition of the errors committed at the end of the last century, on the occasion of a similar operation upon several ships, will no doubt be avoided. The errors committed at that time have been described by Mr Wilson, as previously quoted, and are ascribed by him to a want of sufficient scientific knowledge; but as this is not the case at the present time, the country may now expect a very fine class of vessels to be the result.

It may also be remarked, that the introduction of the system of distilling the necessary supply of fresh-water on board the ships, and thus obviating the necessity of carrying so great a weight of fresh-water, has materially facilitated the arrangements for these alterations.

The history of ship-building in the royal navy up to the present time (1859), cannot be closed without reference to the class of small gun-boats and of iron-cased floating batteries recently introduced into the service. The gun-

History.

boats are of three classes, varying slightly in size and horse-power. The greater proportion of them are 106 ft. long between the perpendiculars, 22 ft. beam and 8 ft. deep, and are fitted with high-pressure engines of sixty horse-power. They are of 233 tons burden, and their draught of water, when ready for sea, is about 6 ft. The importance of this class of vessels as a protection against invasion cannot be overrated. The introduction of steam as a mechanical agent for the propulsion of vessels, independent of wind and tide, brings back almost the same state of things as existed when hostile fleets were composed of rowing galleys. The supremacy on the ocean which this country has so long held by means of the experience of such a large proportion of her population as seamen, must now depend on other sources of strength, and it behoves the nation to make preparations suitable to meet the altered circumstances. If our fleet were to suffer any reverse, and thus leave the sea free to an enemy; or if an enemy came to a determination to try and evade our fleet, and land an army on our shores, that army might be embarked at many different points; and with steam as an agent, the different portions of it might, with almost perfect certainty, meet at any appointed time at any spot. When once upon our coasts, they could move along them with a rapidity far beyond that at which any troops on shore could follow them. The importance, then, of keeping up a large and effective force of steam gun-boats, to lie, in the time of an expected invasion, in every bay and creek of our indented shores, is evident. For the construction of a fleet of such vessels, iron is fortunately the most valuable material, as the evils attending its use in large men-of-war will not militate against its use in these vessels. If they should be struck by shot, the men will be above the splinters, and by building these vessels with their frames very far apart, and with a strong inner and outer sheathing, both water-tight on every frame, they may be made almost unsinkable. The chief advantage, however, of iron for such vessels is its durability, if moderate care be taken to construct them in such a manner, that all the parts may be kept painted, and then that they be periodically cleaned and painted. Iron vessels so constructed and hauled up on shore, and so treated, might be considered as almost free from decay.

The floating batteries, coated with iron-plates 4 inches thick, appear at first sight to be most formidable vessels. Some of these have been built without any reference to speed, but with merely as much steam power as will give them the power of locomotion. Two others are now being built with great steam-power, and with finely-formed bodies, and these are therefore intended to have great speed. They are not protected at the bow and at the stern, but only in midships, and this part is separated from the ends by strong iron bulkheads, so that the centre portion is, as it were, a citadel into which the men may retire when attacked. Their cost is estimated at about L.250,000 each; and this very large expenditure will necessarily prevent their number being greatly increased. It may be expected, therefore, that the nation which has the command of the sea, will send small vessels of superior speed, and armed with guns capable of penetrating the plates of these batteries, to watch them and prevent their being brought against the ordinary vessels composing the fleet. Whatever speed these batteries may attain, it cannot be doubted but that light vessels, unencumbered with such weight, may be built to surpass them as soon as their speed is known.

Table of the British Navy, extracted from the Navy List, October 1859.

Class.	Propelling power.	Guns.	In commission.	In ordinary, and repairing for service.	Harbour vessels, hulks, &c.	Building.	Totals.

Frigates, iron-cased, not yet in Navy-list—building	...	...	...	...	...	...	4

By a return published during this year, it appears that the total number of ships of all classes belonging to the navies of other kingdoms is as follows:—

France	448	Austria	135
Russia	164	Portugal	37
Sweden—principally small vessels	311	Sardinia	28
		Prussia	55
Norway	143	Greece	26
Denmark	120	Turkey	49
United States	79	Brazil	27
Holland	139	Peru	15
Belgium	7	Chili	5
Spain	82	Mexico	9
The Two Sicilies	121		

In the merchant-service the screw for some time made but little progress. A company trading to Rotterdam, Messrs Laming and Company, were amongst the first to adopt it; and the mercantile marine owes much to their enterprising spirit in this respect. Their vessels were very successful, and attracted much attention from the time of their first introduction; and doubtless much of their immediate success may be attributed to men of high stand-

Extract from Return of British Merchant-Shipping by the Registrar-General of the Board of Trade.

Year.	Number and Tonnage of New Vessels Built and Registered in the British Empire in each Year.				Total Number of Registered Merchant-Vessels belonging to the British Empire in each Year.						
	Sailing Vessels.		Steamers.		Sailing Vessels.		Steamers.		Total.		Men.

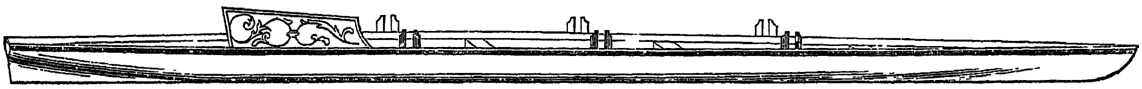
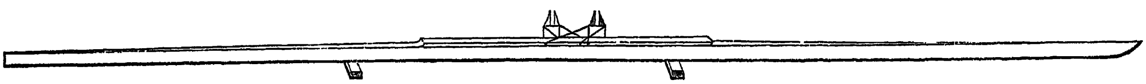
ing in their respective professions of ship-builders and engineers being employed in their construction, and being left unfettered to work out the end that was desired. From that time screw-vessels, constructed of iron, began rapidly to supersede paddle-wheel steamers and sailing vessels, especially for the conveyance of perishable merchandize, such as fruit and provisions; and the great capability of combining sailing and steaming which the screw affords, will no doubt tend to the continued increase of auxiliary steamers. The preceding table of the merchant-shipping of the country shows the extent to which the substitution of steamers for sailing vessels is taking place.

Reference has been previously made to the beneficial influence of the yacht clubs throughout the country. The English yachts were supposed to be unrivalled in speed; and in 1851 a challenge cup was given, open to the whole world for competition. A yacht from America, however, came over to this country, and carried off the prize. She soon showed such great superiority that the favourite English yachts at once gave up the contest, and it appeared likely that she would be allowed to walk over the course. To prevent this the late Mr Robert Stephenson entered his yacht, the Titania, built by Mr Scott Russell, to compete with her, and thus give her an opportunity of showing the extent of her superiority, and on what points that superiority was greatest. Representations of these two yachts are given in Plates V. and VI., and their relative performances and qualities will be examined hereafter. Though the introduction of steam has done much to lessen the interest taken in yachting, yet it is to be hoped that the valuable encouragement given to naval architects, and to the maritime predilections of the country by yachting clubs will be continued, and that many will follow the example already set by a few spirited men, of placing a small amount of auxiliary steam-power in their yachts with screw-propellers. This is done without impairing their beauty, and renders them certain in their movements when desired.

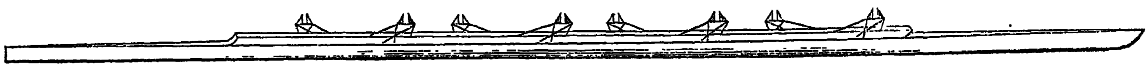
In connection with this subject, and as a means of forming a taste for it, the rowing and racing boats of the youths at public schools, and of the young men at the universities and elsewhere, may be mentioned. The following may be taken as the average performances of such boats at the present day. The drawings and the dimensions are from boats built by Messrs Searle and Sons of Lambeth, London:—



Randan Gig, 28 Feet Long.
A Pleasure Boat for three Pairs of Sculls; or for a Pair of Sculls in the middle, and with a single Oar or Scull forward and aft in addition when desired.



A Sculling Outrigger, 30 Feet Long.
New Style for Racing in Smooth Water.



Eight-Oared Outrigger, 60 Feet Long.
New Style for Racing in Smooth Water.

Eight-Oared Cutter, 60 Feet Long.
The Old Style of Racing Boat, or for Water for which the Outrigger is considered of too slight a Build.

Description of Boat.	Length.	Breadth.	Depth.	Weight.	Maximum speed per hour in still water.
Outrigger Racing Boats—	Feet.	Ft. In. Ft. In.		lb.	Miles.
Outrigger sculling boat	32	0 10 to 1 2	8½ in.	30 to 40	6
„ pair-oared	34	1 3 to 1 6	9 to 11 in.	45 to 55	6½ to 7
„ four-oared	42 to 45	1 10 to 2 3	1 foot.	100 to 112	8½ to 9
„ six-oared	50 to 54	2 0 to 2 4	1 „	150 to 190	9 to 9½
„ eight-oared	57 to 65	2 2 to 2 4	1 „	280 to 330	9½ to 10
Racing Boats of the old style—			Ft. In. Ft. In.		
Sculling boat	30	3 4 to 3 6	1 0 to 1 2	55 to 60	5½
Randan wherry	32	3 4 to 3 6	1 0 to 1 3	100 to 140	6
Four-oared cutter	40 to 42	3 6 to 3 8	1 1 to 1 3	224 to 280	7½ to 8
Six-oared cutter	45 to 50	3 6 to 3 8	1 1 to 1 3	336 to 376	8
Eight-oared cutter	54 to 58	3 6 to 3 8	1 1 to 1 3	520 to 600	8½ to 9
The lighter kind of Pleasure Boats—					
Pair-oared gig	23 to 25	3 6 to 3 8	1 foot 4 in.	180 to 200	4 to 4½
Randan gig	27 to 30	3 6 to 3 8	1 „ 4 „	200 to 224	5
Four-oared gig	40 to 42	3 4 to 3 6	1 „ 3 „	250 to 300	6½ to 7
Six-oared gig	55 to 48	3 4 to 3 6	1 „ 3 „	350 to 400	7
Eight-oared gig	54 to 58	3 2 to 3 4	1 „ 2 „	560 to 620	7½

To pass from these diminutive but beautiful specimens of naval architecture, the last great work which requires to be noticed in this brief outline of the history of the rise and progress of ship-building is the construction of the Great Eastern, Plate VIII. The dimensions of this vessel, as given on the plate, are so far beyond those of ordinary vessels, that it is necessary to draw particular attention to them. At the period of writing this article she has not been to sea except for one or two trial trips. Her performances will be discussed hereafter, but the results predicted by science as to her speed, with a given amount of steam-power, appear to have been realized. How far mercantile enterprise will be benefited by the construction of vessels of her magnitude remains to be proved.

Calculations incidental to designing a Ship.

DESCRIPTION OF THE MANNER OF PERFORMING THE CALCULATIONS INCIDENTAL TO DESIGNING A SHIP, WITH INVESTIGATIONS OF SOME OF THE PRINCIPAL ELEMENTS OF THE DESIGN.

Theory.

The labours of the numerous men of science who have devoted either the whole or a portion of their attention to the various problems embraced in the theory of ships, have left but few of its abstract principles uninvestigated; most of the proportions of a ship have been examined, and the laws on which they depend clearly defined, either by the aid of mathematical demonstration, or by experimental induction. There are, however, some questions which, though sound in theory, still depend on the results of physical experiments for perfecting their practical application.

Many of the elements of naval construction are dependent on the known laws of nature; and it may now be said that the principal difficulties of these are surmounted, and are familiar to the instructed naval architect. These are of themselves sufficient to insure the attainment of a certain and considerable degree of excellency in a ship, to give it a preponderance of any given quality, to discover the causes of any bad quality, and to point out the means of providing a remedy for the faults discovered.

The forces which act upon a ship in motion, in a fluid, even though the fluid be at rest, are as yet but imperfectly defined by mathematicians; and the elements of naval construction dependent on the laws regulating them are, therefore, less known and less certain in their application. The form of a ship's body need not, however, remain imperfect, because the curve of the solid of least resistance is uncertain, since enough has resulted from the consideration of the nature of that solid to prove its inapplicability to vessels in general; and theoretic perfection of the science in this particular would, therefore, be of no practical utility.

A very unphilosophic mode of reasoning is frequently applied to the question of the application of the exact sciences to naval architecture. It has been argued, that because men without any great amount of scientific knowledge have produced good ships, therefore the exact sciences are not necessary for the advancement of naval architecture. In such instances the success has resulted in some cases from chance, in others from induction after a succession of failures, but more frequently from the results of observations on other good ships; and in all these cases, wherever the changes from a foregoing example have been of any moment, the result has been a matter of doubt until tested by trial after completion. It is true that the scientific naval architect cannot effect, by any mathematical process, the synthetical composition of a perfect ship, but he may, by the application of the principles fully established and known to him, produce one with a full confidence of its possessing a preponderance of those qualities which he has considered it desirable that it should possess. The mistake is in the assumption that men of science consider that the theory of naval architecture is already perfected, and is a definite science, whereas this is far from being the case; and it can only be advanced gradually to a greater degree of perfection by an analysis of the actual performances of ships at sea, collected and registered, and the abstract sciences then brought to bear upon them. In every science a perfect theory is the result of the perfection of the science. The time is gone by, when a theory was first formed, and facts were then warped or twisted to suit the pre-conceived theory.

It is now proposed to proceed to show, in as concise a manner as possible, the method of performing the calculations necessary to determine the essential elements of the design of a ship's body, and which are required in the course of preparing the original draught or drawing. The rules to find the areas of plane figures, bounded by straight lines and curves, will first be given; and afterwards those for finding the volumes of solids, bounded by planes and curvilinear spaces.

To find the area of a plane area, bounded by straight lines and a curve.

Simpson's rules for finding the areas of plane surfaces.

ART. 1. If the area is symmetrical in regard to the line $A_1\ A_n$, that is, if a line $A_1 A$ can be found to divide the area into two equal parts, as $A_1\ a_n$ and $A_1\ b_n$; –

Divide this line (or axis) into a convenient number of equal parts, taking care to have an *even* number of such parts, then draw the lines $A_1 a_1$, $A_2 a_2$, $A_3 a_3$, &c., $A_n a_n$ at right angles to the line $A_1 A_n$, through the points A_1, A_2, A_3, &c., A_n, and meeting the curve in the points a_1, a_2, a_3, &c., a_n, these lines being called ordinates;

The second, $A_2 a_2$, fourth, $A_4 a_4$, &c., are called the EVEN ordinates. The *third* $A_3 a_3$, fifth $A_5 a_5$, &c., are called the ODD ordinates (the first and last being omitted).

Then, if these ordinates be measured on the same scale as the equal distances $A_1 A_2$, $A_2 A_3$, &c., the following rules will give the area of the figure :—

RULE I.—*To the sum of the first and last ordinates add four times the sum of all the* EVEN *ordinates, and twice the sum of all the* ODD *ordinates (omitting the first and last); multiply this final sum by the common distance between the ordinates, divide by* 3, *and the result will be the area (nearly).*

Note 1.—The following is the usual demonstration given to this rule, which is due to Thomas Simpson, who was Professor of Mathematics at Woolwich, about the middle of the last century :—

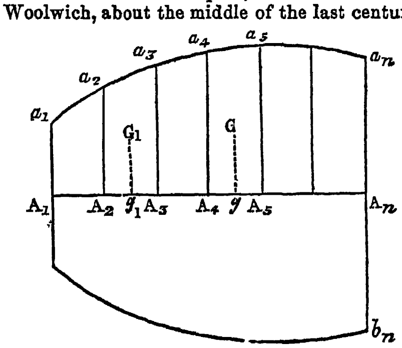


Fig. 3.

Referring to fig. 3,

$$\text{Put } A_1\, a_1 = \alpha_1,\ A_2\, a_2 = \alpha_2,\ A_3\, a_3 = \alpha_3, \text{ \&c., } A_n\ a^n = \alpha_n,$$
$$A_1 A_2 = A_2 A_3 = A_3 A_4, \text{ \&c., } A_{n-1} A_n = h$$

We suppose a parabolic curve, the equation to which is

$$y = A + B x + C x^2 \quad \ldots\ldots\ldots\ldots \quad (1)$$

to pass through the *three* points a_1, a_2, a_3; for since (1) contains three arbitrary constants A, B, C, we can, as is well known, make the curve (1) pass through three given points. Now, since (1) passes through a_1, we know (if A_1 be taken as origin) that $y = \alpha_1$ when $x = o$; when $x = h$, $y = \alpha_2 = A_2\ a_2$, and $y = \alpha_3 = A_3\ a_3$ when $x = 2\ h$; hence we have the following equations :—

$\alpha_1 = A$ . . (2) $\alpha_2 = \alpha_1 + B\,h + C\,h^2$ . . (3) $\alpha_3 = \alpha_1 + 2\,B\,h + 4\,C\,h^2$ . . (4) between (3) and (4) we readily determine B and C, viz. :—

$$B = \frac{4\,\alpha_2 - \alpha_3 - 3\,\alpha_1}{2\,h} \quad \ldots\ldots \quad (5)$$

$$C = \frac{\alpha_3 - 2\alpha_2 + \alpha_1}{2\,h^2} \quad \ldots\ldots \quad (6)$$

Introducing these values into (1), we obtain

$$y = \alpha_1 + \frac{4\,\alpha_2 - \alpha_3 - 3\,\alpha_1}{2\,h}x + \frac{\alpha_3 - 2\,\alpha_2 + \alpha_1}{2\,h^2}x^2.$$

But by the Integral Calculus we know that the area of a curve is represented by

$\int y\,dx$, taken between proper limits. In the present case these limits are o and $2h$.

$$\therefore \text{ area of } A_1\ a_3, \text{ or} \int_0^{2h} y\,dx = 2\alpha_1\,h + \left(\frac{4\alpha_2 - \alpha_3 - 3\alpha_1}{4h}\right)h^2$$

Calculations incidental to designing a Ship.

$+\left(\frac{\alpha_3-2\alpha_2+\alpha_1}{6h^2}\right)h^3$, or area of $A_1\,\alpha_3=\frac{h}{3}\left(\alpha_1+\alpha_3+4\alpha_2\right)$, after a little reduction.

Again, by making a parabola of the same form as (1) pass through the three points α_3, α_4, α_5, we obtain a result precisely similar to the above, that is,

$$\text{area } A_3\;\alpha_5=\frac{h}{3}(\alpha_3+\alpha_5+4\alpha_4, \text{ and}$$

$$\text{area } A_5\;\alpha_7=\frac{h}{3}(\alpha_5+\alpha_7+4\alpha_6),$$

$$\text{area } A^{n}{}_{-2}\,\alpha_n=\frac{h}{3}(\alpha_n{}_{-1}+\alpha_n+4\alpha^{n}{}_{-2}).$$

Adding these areas we find

$$\text{(I.) Area } A_1\,\alpha_n=\frac{h}{3}\left\{\alpha_1+\alpha_n+4\,(\alpha_2+\alpha_4+\alpha_6+\&c., \alpha_{n-2}) + 2\,(\alpha_3+\alpha_5, \&c., \alpha_{n-1})\right\}$$

It ought to be observed that in the application of this, and the following rules, an *odd* number of ordinates are always to be taken, and the nearer the ordinates are taken, that is, the less the common interval, the more nearly will the final result approach the *true* area of the figure.

For those who are not familiar with the Integral Calculus, another demonstration may be obtained, as follows:—

Through the point α_2, draw a tangent to the parabola which passes through α_1, α_2, α_3, and produce $A_1\,\alpha_1$, $A_3\,\alpha_3$, to meet this tangent in the points c and d; join $\alpha_1\,\alpha_3$; intersecting $A_2\;\alpha_2$ in b; through α_1 and c draw $c\,e$ and $\alpha_1\,f$ parallel to $A_1\,A_3$, then it is shown in all works on Conic Sections that $\alpha_1\,\alpha_3$ is parallel to $c\,d$. Hence by Euc. I. 35—

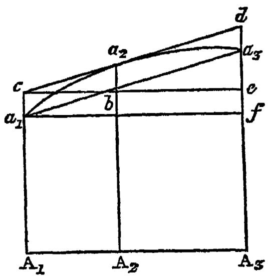

Fig. 4.

Paral^m $\alpha_1\,d$ = paral^m cf, because they are on the same base and between the same parallels $A_1\,c_1$, $A_3\,d$.

$$\text{Now, } A_2\,b=\frac{A_1\,\alpha_1+A_3\,\alpha_3}{2} \text{ and } A_2\,\alpha_2=\alpha_2$$

$$\therefore \text{ area of parabola } \alpha_1\,b\alpha_3\,\alpha_2\,\alpha_1=\frac{2}{3}\text{paral}^{m}\,\alpha_1\,d=\frac{2}{3}\text{paral}^{m}\,cf\text{ [1]}$$

$$=\frac{2}{3}\left(\alpha_2-\frac{\alpha_1+\alpha_3}{2}\right)\times 2h, \text{ since } A_1\,A_3=\alpha f=2h.$$

$$\text{Also area of trapezoid } A_1\,\alpha_1\,\alpha_3\,A_3=\left(\frac{A\alpha_1+A_3\,\alpha_3}{2}\right)A_1\,A_3 = h\,(\alpha_1+\alpha_3).$$

Adding these two areas, we obtain that of the whole figure

$$A_1\,\alpha_1\,\alpha_2\,\alpha_3\,A_3=\frac{h}{3}\left\{3\alpha_1+3\alpha_3+4\alpha_2-2\alpha_1-2\alpha_3\right\}$$

$$=\frac{h}{3}\left\{\alpha_1+4\alpha_2+\alpha_3.\right\}$$

By repeating this process for the area of the figures $A_3\,\alpha_3\,\alpha_4\,\alpha_5\,A_5$, &c., &c., and adding the results, we obtain for the whole area $A_1\,\alpha_n$ the same result as before.

If α_2 were less than α_1, the parabola would be convex towards $A_1\,A_3$; but the same rule would still apply, for A_2b would then be equal to $\frac{\alpha_1+\alpha_3}{2}-\alpha_2$, and this introduced into the form for finding the area of the parabola, leads to the same result as that already obtained.

Another demonstration, on different principles, will be given in Note (3.)

RULE II.—*To the sum of the first and last ordinates, add* THREE TIMES *the sum of the second, third, fifth, sixth, eighth, ninth, &c., ordinates, and* TWICE *the sum of the fourth, seventh, tenth, thirteenth, &c., ordinates (omitting the last ordinate); multiply this final sum by three times the common distance between the ordinates, divide the product by 8, and the result will give the area (nearly).*

Note 2.—To obtain what naval architects call the "Second Rule," we suppose a parabola, the equation to which is

$$y=A+Bx+Cx^2+Dx^3 \quad \ldots\ldots \quad (1)$$

to pass through the four points α_1, α_2, α_3 α_4 (fig. 1), the four constants being determined by these conditions; that is, when x takes the successive values o, h, $2h$, $3h$; y becomes α_1, α_2, α_3, and α_4; hence the following equations:

$$\alpha_1=A \ldots\ldots (2) \because \text{when } x=o \;\; y=\alpha_1$$

$$\alpha_2-\alpha_1=Bh+Ch^2+Dh^3 \ldots (3) \because \text{when } x=h_1\; y=\alpha_2$$

$$\alpha_3-\alpha_1=2Bh+4Ch^2+8Dh^3 \ldots (4) \because \text{when } x=2h_1\, y=\alpha_3$$

$$\alpha_4-\alpha_1=3Bh+9Ch^2+27Dh^3 \ldots (5) \because \text{when } x=3h_1\, y=\alpha_4$$

$$(4)-(3)\times 2 \text{ gives } \alpha_3-2\alpha_2+\alpha_1=2Ch^2+6Dh^3 \ldots (6)$$

$$(5)+(3)-(4)\times 2 \text{ gives } \alpha_4-2\alpha_3+\alpha_2=2Ch^2+12Dh^3 \ldots (7)$$

$$(7)-(6) \text{ gives } 6Dh^3=\alpha_4-3\alpha_3+3\alpha_2-\alpha_1 \ldots (8)$$

$$\text{From (6) and (8) } 2Ch^2=\alpha_4+4\alpha_3-5\alpha_2+2\alpha_1 \ldots (9)$$

$$\text{From (3), (8) and (9) } 6Bh=2\alpha_4-9\alpha_3+18\alpha_2-11\alpha_1 \ldots (10)$$

$$\text{But area, or} \int_o^{3h} y\,dx=\int_o^{3h}\left\{A+Bx+Cx^2+Dx^3\right\}dx$$

(we write the limits of x, o and $3h$, because at A_1, x is o, and at A_4, x is $3h$).

$$\therefore \text{ Area } A_1\,\alpha_4=\frac{3h}{8}\left\{8A+12Bh+24Ch^2+54Dh^3.\right\}$$

Introducing the values of A, B, C, and D, given by the above equations, we find, after some obvious reductions,

$$\text{Area } A_1\,\alpha_4=\frac{3h}{8}\left\{\alpha_1+\alpha_4+3\,\alpha_2+3\,\alpha_3\right\} \quad \ldots \quad (11.)$$

In like manner, by making a curve similar to (1) pass through the points α_4, α_5, α_6, α_7, we have

$$\text{Area } A_4\,\alpha_7=\frac{3h}{8}\left\{\alpha_4+\alpha_7+3\,\alpha_5+3\,\alpha_6\right\} \quad \ldots \quad (12.)$$

$$\text{Area } A_7\,\alpha_{10}=\frac{3h}{8}\left\{\alpha_7+\alpha_{10}+3\,\alpha_8+3\,\alpha_9\right\} \quad \ldots \quad (13.)$$

$$\vdots \qquad \vdots$$

$$\text{Area } A_{n-3}\alpha_n=\frac{3h}{8}\left\{\alpha_{n-3}+\alpha_n+3\,\alpha_{n-2}+3\,\alpha_{n-1}\right\} \quad \ldots \quad \text{(N.)}$$

Adding equations (11), (12), (13), &c., (N), we get

$$\text{(II.) Area } A_1\,\alpha_n=\frac{3h}{8}\left\{\alpha_1+\alpha_n+3\,(\alpha_2+\alpha_3+\alpha_5+\alpha_6+\&c., \alpha_{n-2}+\alpha_{n-1})+2\,(\alpha_4+\alpha_7+\alpha_{10}+\&c., \alpha^{n}{}_{-3})\right\}$$

It will be seen from the foregoing method that we may make a curve of the form

$$y=A+Bx+Cx^2+Dx^3+Ex^4+\&c., Nx_{n-1}$$

pass through n points, taking care that the equation shall contain n arbitrary constants, to be determined by the conditions that the curve may pass through α_1, α_2, α_3, α_4, &c., α_n (fig. 3, page 140), when x and y are respectively $x=o$, $x=h$, $x=2\,h$, &c., $x=(n-1)\,h$,

$$y=\alpha_1,\; y=\alpha_2,\; y=\alpha_3, \;\&c.,\; y=\alpha_n,$$

α_1, α_2, α_3, &c., and h, having the same interpretation as before; the ordinates being taken at equal distances apart, as on this hypothesis the calculation of the area is much simplified.

Rules obtained after this manner for any given number of ordinates will, in general, give us the area of the figure more correctly than if we employed the preceding rules, because in the latter case we suppose a continuous curve to pass through the given points, whereas, in the former cases, we have a *series of curves* passing through the given points, and the curvilinear boundary is itself supposed to be a continuous curve. Such rules (for many ordinates) give rise to a great deal of labour in obtaining them, and entail almost as much labour in their application. In the latter case, moreover, logarithms will assist us to some extent, and in the former,

Calculations incidental to designing a Ship.

[1] The equation to a parabola being $y^2=4\,m\,x$, or $y=2\,m^{\frac{1}{2}}\,x^{\frac{1}{2}}$ . . . . . . (1)

$$\text{Area, or} \int_o^x y\,dx=2m^{\frac{1}{2}}\int_o^x x^{\frac{1}{2}}\,dx=\frac{4a^{\frac{1}{2}}\,x^{\frac{3}{2}}}{3}=\frac{2\,xy}{3} \text{ by (1)}$$

$$=\frac{2}{3} \text{ circumscribed parallelogram.}$$

Calculations incidental to designing a Ship.

there are some remarkable properties of the natural numbers connected with the determination of the arbitrary constants, and on which perhaps more light may hereafter be thrown. We have remarked some curious properties of the squares, cubes, &c., of numbers connected with the eliminations. There can be no doubt that many other rules of a very simple kind may be obtained on the condition that any number of the constants may disappear from the general equation, which is equivalent to as many conditions.

Emerson, in his *Arithmetic of Infinites*, published by Nourse in the year 1767, gives the following formulæ, obtained by the foregoing processes—from one up to nine ordinates.

Area $= h\alpha_1$ . . . . for one ordinate.

$= \frac{h}{2}(\alpha_1+\alpha_2)$ . . . . for two ordinates.

(1) $= \frac{h}{3}(\alpha_1+\alpha_3+4\alpha_2)$ . . . . for three ordinates.

(2) $= \frac{3h}{8}\left\{\alpha_1+\alpha_4+3(\alpha_2+\alpha_3)\right\}$ . . . . for four ordinates.

(3) $= \frac{h}{25}\left\{7(\alpha_1+\alpha_5)+32(\alpha_2+\alpha_4)+12\alpha_3\right\}$ for five ordinates.

(4) $= \frac{5h}{288}\left\{19(\alpha_1+\alpha_6)+75(\alpha_2+\alpha_5)+50(\alpha_3+\alpha_4)\right\}$ six do.

(5) $= \frac{h}{140}\left\{41(\alpha_1+\alpha_7)+216(\alpha_2+\alpha_6)+27(\alpha_3+\alpha_5)+272\alpha_4\right\}$ for seven ordinates.

(6) $= \frac{7h}{17280}\left\{751(\alpha_1+\alpha_8)+3577(\alpha_2+\alpha_7)+1323(\alpha_3+\alpha_6)+2989(\alpha_3+\alpha_4)\right\}$ for eight ordinates.

(7) $= \frac{4h}{14175}\left\{989(\alpha_1+\alpha_9)+5888(\alpha_2+\alpha_8)-928(\alpha_3+\alpha_7)+10496(\alpha_4+\alpha_6)-4540\alpha_5\right\}$ for nine ordinates.

Where extreme accuracy is required, these may be combined such a way as to give the area. For instance, if there were fifteen ordinates in a figure, (5) and (7) may be combined, remembering that the last ordinate of (5) becomes the first in (7), &c., &c.

When seven ordinates are considered sufficient, the following elegant rule, due to the late Mr Thomas Weddle, of the Military College, Sandhurst, may be employed :—

RULE III.—*When* SEVEN *ordinates are employed.*[1] *To five times the sum of the* EVEN *ordinates, add the fourth, or middle ordinate, and all the odd ordinates ; multiply this sum by* THREE TIMES *the common distance between the ordinates, divide by* 10, *and the result will give the area* (nearly).[2]

Note 3.—The Calculus of Finite Differences may be advantageously employed to approximate to the areas of surfaces, lengths of curves, volumes of solids, centres of gravity, moments of inertia, &c. For triple integrals may generally be reduced to integrals of the form

$$\int_{x_1}^{x_2} u\,dx$$

where u represents a function of x, or $f(x)$, as it is usually written, and x_1, x_2 represent the limits of the integral.

Now, if we suppose x to vary by the constant difference Δx, we may suppose $z = \frac{x}{\Delta x}$, and if $\alpha_1, \alpha_2, \alpha_3$, &c., α_n be the values of u when $z = o, 1, 2, 3$, &c., n, we have, by Taylor's theorem,

$$u = \alpha_1 + z\Delta\alpha_1 + z(z-1)\frac{\Delta^2\alpha_1}{1\cdot2}, + z(z-1)(z-2)\frac{\Delta^3\alpha}{1\cdot2\cdot3} + \text{\&c., ...} \quad (1.)$$

But by hypothesis Δx is constant, and according to the notation we have previously employed, we may suppose it $= h \therefore \frac{x}{h} = z$, and $\frac{dx}{h} = dz$. Multiplying each side of (1) by these differentials, and integrating, we have

$$\frac{1}{h}\int u\,dx = z\alpha_1 + \frac{z^2}{2}\Delta\alpha_1 + \left(\frac{z^3}{3}-\frac{z^2}{2}\right)\frac{\Delta^2\alpha_1}{1\cdot2} + \left(\frac{z^4}{4}-\frac{3z^3}{3}+\frac{2z^2}{2}\right)\frac{\Delta^3\alpha}{1\cdot2\cdot3}$$

$$+\left(\frac{z^5}{5}-\frac{6z^4}{4}+\frac{11z^3}{3}-\frac{6z^2}{2}\right)\frac{\Delta^4\alpha_1}{1\cdot2\cdot3\cdot4} + \left(\frac{z^6}{6}-\frac{10z^5}{5}+\frac{35z^4}{4}-\frac{50z^3}{3}+\frac{24z^2}{2}\right)\frac{\Delta^5\alpha_1}{\lfloor 5}$$

$$+\left(\frac{z^7}{7}-\frac{15z^6}{6}+\frac{85z^5}{5}-\frac{225z^4}{4}+\frac{274z^3}{3}-\frac{120z^2}{2}\right)\frac{\Delta^6\alpha_1}{\lfloor 6}$$

$$+\left(\frac{z^8}{8}-\frac{21z^7}{7}+\frac{175z^6}{6}-\frac{735z^5}{5}+\frac{1624z^4}{4}-\frac{1764z^3}{3}+\frac{720z^2}{2}\right)\frac{\Delta^7\alpha_1}{\lfloor 7}$$

$$+\left(\frac{z^9}{9}-\frac{28z^8}{8}+\frac{322z^7}{7}-\frac{1960z^6}{6}+\frac{6769z^5}{5}-\frac{13132z^4}{4}+\frac{13068z^3}{3}-\frac{5040z^2}{2}\right)\frac{\Delta^8\alpha_1}{\lfloor 8}$$

$$+\left(\frac{z^{10}}{10}-\frac{36z^9}{9}+\frac{546z^8}{8}-\frac{4536z^7}{7}+\frac{22449z^6}{6}-\frac{67284z^5}{5}+\frac{118124z^4}{4}-\frac{109584z^3}{3}+\frac{40320z^2}{2}\right)\frac{\Delta^9\alpha_1}{\lfloor 9}$$

$$+\left(\frac{z^{11}}{11}-\frac{45z^{10}}{10}+\frac{870z^9}{9}-\frac{9450z^8}{8}+\frac{63273z^7}{7}-\frac{269325z^6}{6}+\frac{723680z^5}{5}-\frac{1172700z^4}{4}+\frac{1026576z^3}{3}-\frac{362880z^2}{2}\right)\frac{\Delta^{10}\alpha_1}{\lfloor 10}$$

$$+\left(\frac{z^{12}}{12}-\frac{55z^{11}}{11}+\frac{1320z^{10}}{10}-\frac{18150z^9}{9}+\frac{157773z^8}{8}-\frac{902055z^7}{7}+\frac{3416930z^6}{6}-\frac{8409500z^5}{5}+\frac{12753576z^4}{4}-\frac{10628640z^3}{3}+\frac{3628800z^2}{2}\right)\frac{\Delta^{11}\alpha_1}{\lfloor 11}$$

$$+\left(\frac{z^{13}}{13}-\frac{66z^{12}}{12}+\frac{1925z^{11}}{11}-\frac{32670z^{10}}{10}+\frac{357423z^9}{9}-\frac{2637558z^8}{8}+\frac{13339545z^7}{7}-\frac{45995730z^6}{6}+\frac{105258876z^5}{5}-\frac{150917976z^4}{4}+\frac{120543840z^3}{3}-\frac{35916800z^2}{2}\right)\frac{\Delta^{12}\alpha_1}{\lfloor 12}$$

$$+ \text{\&c.,} + \text{\&c.,} \quad \ldots \quad (2.)$$

The coefficients in each of these terms are readily obtained by multiplying $(p-1)(p-2)(p-3)(p-4)(p-5)$, &c. $(p-n)$ together.

If we take this integral between the limits $z = 0$ and $z = 2$, which correspond to $x = 0$ and $x = 2h$, after multiplying by h.

$$\int_0^{2h} u\,dx = h\left\{2\alpha_1 + 2\Delta\alpha_1 + \frac{1}{3}\Delta^2\alpha_1 - \frac{1}{90}\Delta^4\alpha_1 + \frac{1}{90}\Delta^5\alpha_1 - \frac{37}{3780}\Delta^6\alpha_1 + \text{\&c.}\right\}$$

But by the principles of the Calculus of Finite Differences :

$$\Delta\alpha_1 = \alpha_2 - \alpha_1$$
$$\Delta^2\alpha_1 = \alpha_3 - 2\alpha_2 + \alpha_1$$

$$\therefore \int_0^{2h} u\,dx = \frac{h}{3}\left\{\alpha_1 + 4\alpha_2 + 2\alpha_3 - \frac{1}{30}\Delta^4\alpha_1 + \frac{1}{30}\Delta^5\alpha_1 - \frac{37}{1260}\Delta^6\alpha_1 + \text{\&c.}\right\}$$

Now, if we add similar expressions for the area included between $x = 2h$ and $x = 4h$; $x = 4h$ and $x = 6h$, &c. $x = (n-2)$ and $x = nh$ (n being an even number).

[1] Seven, thirteen, nineteen, &c., ordinates, may be employed on the same hypothesis, as is mentioned hereafter.
[2] The fourth ordinate is considered among the *even* ordinates.

Calculations incidental to designing a Ship.

$$\int_0^{nh} u\,dx = \frac{h}{3}\Big\{\alpha_1 + \alpha_{n+1} + 4(\alpha_2 + \alpha_4 + \alpha_6 + \&c. + \alpha_{n-2})$$
$$+ 2(\alpha_3 + \alpha_5 + \alpha_7 + \&c. + \alpha_{n-1}\}.$$
$$- \frac{1}{30}(\Delta^4\alpha_1 + \Delta^4\alpha_2 + \Delta^4\alpha_4 + \&c. \quad \Delta^4\alpha_{n-1}).$$
$$+ \frac{1}{30}(\Delta^5\alpha_1 + \Delta^5\alpha^2 + \Delta^5\alpha_4 + \&c. \quad \Delta^5\alpha_{n-1}).$$
$$- \frac{37}{1260}(\Delta^6\alpha_1 + \Delta^6\alpha_2 + \&c. \quad \&c. \qquad).$$
$$+ \quad \&c. \quad \&c. \quad \&c. \qquad \Big\} \ldots . (3.)$$

The first line corresponds to the Rule we have already obtained (I.) by supposing a parabola to pass through the extremities of the ordinates α_1, α_2, α_3; and another through α_3, α_4, α_5, &c.

The following terms are the correction of the first line; hence, when great accuracy is required, the following results may be taken into account.

To obtain Rule (III.), we only have to suppose the integral (1) taken between the limits $z = 0$ and $z = 6$, or $x = 0$ and $x = 6h$, as was done by Mr Weddle in his demonstration, given in the *Dublin and Cambridge Mathematical Journal* for February 1856, which is similar to this:

$$\therefore \int_0^{6h} u\,dx = h\Big\{6\alpha_1 + 18\,\Delta\alpha_1 + 27\,\Delta^2\alpha_1 + 24\,\Delta^3\alpha_1 + \frac{123}{10}\Delta^4\alpha_1$$
$$+ \frac{33}{10}\Delta^5\alpha_1 + \frac{41}{140}\Delta^6\alpha_1 + \&c.\Big\} \ldots\ldots\ldots\ldots\ldots . (4.)$$

And we may suppose *sixth* differences *constant*, and then all the terms after $\Delta^6\alpha_1$ in (4) will vanish; but $\frac{41}{140}$ differs from $\frac{42}{140}$ by the small fraction $\frac{1}{140}$; hence, instead of $\frac{41}{140}$ we may write $\frac{42}{140}$ or $\frac{3}{10}$ without material error. Replacing $\Delta\alpha_1$ by $\alpha_2 - \alpha_1$, $\Delta^2\alpha_1$ by $\alpha_3 - 2\alpha_2 + \alpha_1$, $\Delta^3\alpha_1$ by $\alpha_4 - 3\alpha_3 + 3\alpha_2 - \alpha_1$ &c., after some obvious reductions (4) becomes

$$\int_0^{6h} u\,dx = \frac{3h}{10}\Big\{\alpha_1 + \alpha_3 + \alpha_5 + \alpha_7 + 5(\alpha_2 + \alpha_6) + 6\alpha_4\Big\}$$
$$= \frac{3h}{10}\Big\{\alpha_1 + \alpha_3 + \alpha_4 + \alpha_5 + \alpha_7 + 5(\alpha_2 + \alpha_4 + \alpha_6)\Big\} \ldots\ldots\ldots . (5.)$$

"From the foregoing investigation, it is clear, that formula (5.) gives the *exact* area, when fifth differences are constant, while it differs (in excess) from the true value by $\frac{1}{140}\Delta^6\beta$ when *sixth*, or even *seventh*, differences are constant. In other cases it will give the area very nearly, providing the differences, beginning at the sixth, are small."[1]

As many rules as we please may be obtained by integrating (1.) from $z = 0$ to $z = 1$, $z = 0$ to $z = 2$, $z = 0$ to $z = 3$, $z = 0$ to $z = 4$, &c.: from $z = 0$ to $z = n$, and, neglecting small quantities, as has been done by Mr Weddle, and by supposing the $(n-1)^{th}$ order of differences constant.[2]

Rule (II.) may be obtained by integrating equations (1.) from $z = 0$ to $z = 3$, which will be the same as supposing a series of parabolas to pass through the extremities of $\alpha_1, \alpha_2, \alpha_3, \alpha_4$; $\alpha_4, \alpha_5, \alpha_6, \alpha_7$, &c., as was the case in formula (3).

In these rules, if the curve passes through A_1 or A_n, the first or last ordinate must be considered 0.

Some examples will now be given on the application of the preceding rules.

(1.) Find the area of a figure, bounded by right lines and a curve, the ordinates of which are taken at 3 feet apart, and measure 1, 2, 3, 4, 5, 4, 3, 2, and 1 feet respectively.

Calculations incidental to designing a Ship.

By Rule (I.)

Ordinates.	Even Ordinates.	Odd Ordinates.
1 1st ord.	2	3
1 last do.	4	5
–	4	3
2 sum of 1st and last ord.	2	—
48 four times sum of even do.	—	11 sum of odd ord.
22 twice sum of odd do.	12 sum of even ord.	2
—	4	—
72	—	22 twice sum of do.
1 = ⅓ common distance.	48 — four times do.	
—		
72 = area.		

By Rule (II.)

64	—	
9 = 3 times com. dist.	48 three times sum of do.	
—		
8)576		
—		

72 = area, which agrees exactly with the area obtained by Rule (I.)

(2.) Find the area of a figure where the ordinates are 10, 12, 13, 14, 13, 12, and 10 feet, respectively, and the common distance 2 feet.

By Rule (I.) $\quad$ Area $= \frac{2}{3}\{10 + 10 + 4(12 + 14 + 12) + 2(13 + 13)\} = 149\frac{1}{3}$ feet.

By Rule (II.) $\quad$ Area $= \frac{3 \times 2}{8}\{10 + 10 + 3(12 + 13 + 13 + 12) + 2 \times 14\} = 148\frac{2}{3}$ feet.

By Rule (III.) $\quad$ Area $= \frac{3 \times 2}{10}\{10 + 13 + 14 + 13 + 10 + 5(12 + 14 + 12)\} = 150$ feet.

(3.) Find the area where the ordinates are 20·75, 21·78, 22·56, 23·79, 22·64, 21·51; and 21·51, the common distance being 6 feet.

By Rule (I.) $\quad$ Area $= \frac{6}{3}\{20{\cdot}75 + 21{\cdot}51 + 4(21{\cdot}78 + 23{\cdot}79 + 21{\cdot}51) + 2(22{\cdot}56 + 22{\cdot}64)\} = 801{\cdot}96$ feet.

By Rule (II.) $\quad$ Area $= \frac{6 \times 3}{8}\{20{\cdot}75 + 21{\cdot}51 + 3(21{\cdot}78 + 22{\cdot}56 + 22{\cdot}64 + 21{\cdot}51) + 2 \times 23{\cdot}79\} = 799{\cdot}4475.$

By Rule (III.) $\quad$ Area $= \frac{6 \times 3}{10}\{20{\cdot}75 + 22{\cdot}56 + 23{\cdot}79 + 22{\cdot}64 + 21{\cdot}51 + 5(21{\cdot}78 + 23{\cdot}79 + 21{\cdot}51)\} = 803{\cdot}97.$

As is stated in Note (3.), Rule (III.) can only be applied to obtain a very near approximation to the true area when the sixth and seventh ordinates are alike, or differ by a very small quantity.

By applying these rules to find the area of the quadrant $A_1\,a_7'$, the radius of which is 6 feet, it will be seen how much the results differ from the true area.

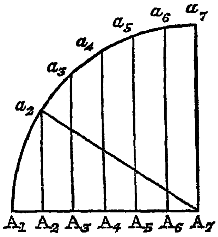

Fig. 5.

[1] The *Dub. and C. Math. Journal*, Feb. 1854.

[2] The coefficients of the various orders of differences have been extended, in order that the reader may obtain some of these rules for himself.

Calculations incidental to designing a Ship.

Divide the radius $A_1 A_7$ into six equal parts (Fig. 5), and erect the ordinates $A_2 a_2$, $A_3 a_3$, &c. observing that $A_1 a_1 = 0$.

$$A_2 a_2 = \sqrt{(A_7 a_2)^2 - (A_7 A_2)^2} = \sqrt{6^2 - 5^2} = \sqrt{11} = 3{\cdot}3163$$
$$A_3 a_3 = \sqrt{(A_7 a_3)^2 - (A_7 A_3)^2} = \sqrt{6^2 - 4^2} = \sqrt{20} = 4{\cdot}4721$$
$$A_4 a_4 = \sqrt{6^2 - 3^2} = \sqrt{27} = 5{\cdot}1961$$
$$A_5 a_5 = \sqrt{6^2 - 2^2} = \sqrt{32} = 5{\cdot}6568$$
$$A_6 a_6 = \sqrt{6^2 - 1^2} = \sqrt{35} = 5{\cdot}9160$$
$$A_7 a_7 \qquad = 6$$

The area found by Rule (I.) $= 27{\cdot}9901$ feet.
" (II.) $= 27{\cdot}9285$ "
" (III.) $= 28{\cdot}0401$ "

Apply formula (5.) given at the end of Note (1.)

$$\text{Area} = \frac{h}{140}\Big\{41(\alpha_1 + \alpha_7) + 216(\alpha_2 + \alpha_6) + 27(\alpha_3 + \alpha_5) + 272\,\alpha_4\Big\}.$$

Where $h = 6$, $\alpha_1 = 0_1$ $\alpha_2 = 3{\cdot}3163$, $\alpha_3 = 4{\cdot}4721$, &c.
And area $= 28{\cdot}05$ feet.

But true area of quadrant $= \dfrac{6^2 \times 3{\cdot}1416}{4} = 28{\cdot}2744$, so that Rule (III.) and formula (5.), in the present case, give the area almost accurately.

(4.) The ordinates of a curve taken 6 feet apart are, 20, 22, 24, 25; 24, 23, and 21 feet, respectively: find the area of the figure.

By Rule (I.) $\text{Area} = \frac{6}{3}\Big\{20 + 21 + 4(22 + 25 + 23) + 2(24 + 24)\Big\} = 834$ feet.

By Rule (II.) $\text{Area} = \frac{3 \times 6}{8}\Big\{20 + 21 + 3(22 + 24 + 24 + 23) + 2 \times 25\Big\} = 832{\cdot}5$ feet.

By Rule (III.) $\text{Area} = \frac{3 \times 6}{10}\Big\{20 + 24 + 25 + 21 + 5(22 + 25 + 23\Big\} = 835{\cdot}2$ feet.

By formula (5.) $\text{Area} = \frac{6}{140}\Big\{20 + 21 + 216(22 + 23) + 27(24 + 24) + 272 \times 25\Big\} = 835{\cdot}5$ feet.

(5.) Find the area, when the ordinates, taken 4 feet apart measure 0, 2·275, 3·476, 4·567, 5·673, 6·451, 5·341, 4·236, 3·254, 3·065, 2·784, 1·876, and 0, respectively.

By Rule (I.) Area $= 174{\cdot}6293$.

(6.) Find the area by Rules (II.) and (III.) when the ordinates, taken 1 foot apart, measure, 0, 1·7684, 2·3457, 3·4567, 3·214, 2·97654, and 2·8543 feet, respectively.

By Rule (II.) Area $= 15{\cdot}2556$, &c.
By Rule (III.) Area $= 15{\cdot}86367$

Displacement.

Art. 2. Def.—By the *Displacement* of a ship is meant the volume of water which the ship displaces when floating on its surface.

Now, by the principles of hydrostatics, it is well known that the *weight* of a body floating in water, or any other fluid, is equal to the weight of the water or fluid displaced. Hence, after obtaining the displacement of a body, it is only necessary to multiply the volume (say in cubic feet) of the displaced fluid, by the weight of a cubic foot of the fluid, in order to obtain the weight of the floating body.

Def.—*By a plane of flotation is meant that section of the vessel, in any position, made by the surface of the water.*

Several general rules have been given to determine the displacement of ships, which can be but approximations to the true results, since the outlines of ships differ so widely, and it is therefore not considered necessary to give them.

In order to find the displacement, the ship is supposed to be divided by any number of equi-distant horizontal planes, that is, planes taken parallel to the load-water line, and also by any convenient number of equi-distant vertical planes, intersecting, of course, the former series of horizontal planes at right angles. These planes are generally projected by the draughtsman on the three plans of the vessel, viz., the body plan, the sheer plan, and half-breadth plan. (See Plate I.)

Calculations incidental to designing a Ship.

As is seen in the half-breadth plan, the ship is divided into two equal portions by a vertical plane, running from stem to stern; and the perpendicular distances measured on each horizontal plane, from their intersection with this plane to the ship's side, are considered as ordinates.

Thus, in the half-breadth plan (Plate I.), F 7 is the projection of the vertical plane which divides the ship into two equal parts, and F*f* E*e* are the ordinates in the horizontal plane, F, 7_n, any number of these horizontal planes may be taken, and for the purposes of calculation they may be numbered 1, 2, 3, 4, &c.; and A. B. C. &c.

The small portions, fore and aft, are usually calculated separately, the horizontal and vertical planes being taken much nearer to each other in consequence of the greater curvature of the vessel at these parts.

The calculation of the displacement may be proceeded with in two ways:—

1st, By finding the *areas* of all the horizontal sections, and employing these as ordinates in Rule (I.) or (II.)

2d, By finding the areas of all the vertical sections, and using these as ordinates in the same rules.

These two results ought to agree.

Or, the rule may be enunciated as follows, ordinates on the half-breadth plan being understood:—

Rule IV. *To the sum of the* first *and* last *horizontal sectional areas, add* four *times the sum of all the* even *horizontal areas, and* twice *the sum of all the* odd *horizontal areas; multiply this final sum by* one-third *the common distance between these horizontal planes, and this result gives one-half the displacement.*

We could not, from what has already been done, *à priori*, conclude that "Simpson's Rule" would enable us to find the volume of a solid, bounded by planes and a curvilinear surface. The following demonstration, however, proves that it holds true.

Note 4.—Let $A_1\, c_3$ represent a portion of such a body, bounded by the planes $A_1 C_3$, $C_3 a_3$, $A_1 a_3$, $C_1 a_1$, $C_1 c_3$, and by the surface $a_1 c_3$, we take the planes $A_1 a_3$, $A_1 c_1$, and $A_1 a_3$, as the three planes of reference, viz., $(x\,y)$, $(y\,z)$, and $(x\,z)$, respectively.

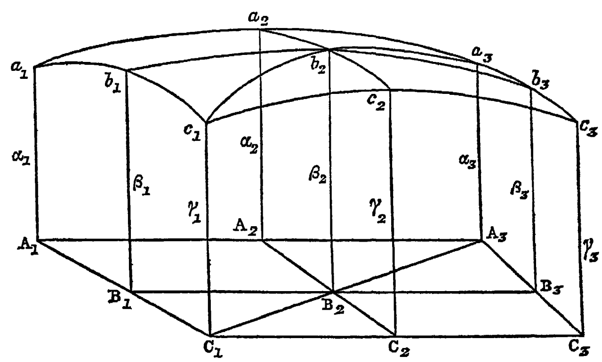

Fig. 6.

Bisect $A_1 A_3$, $A_1 C_1$, $C_1 C_3$, $A_3 C_3$, in the points A_2, B_1 C_2, and B_3, respectively; join $A_2 C_2$, and $B_1 B_3$; through these right lines let planes $A_2\, c_2$, $B_1\, b_3$, be drawn at right angles to the plane $A_1 C_3$, then

$$\text{Assume } A_1 A_2 = A_2 A_3 = B_1 B_2 = B_2 B_3 = C_1 C_2 = C_2 C_3 = h$$
$$A_1 B_1 = B_1 C_1 = A_2 B_2 = B_2 C_2 = A_3 B_3 = B_3 C_3 = k$$
$$A_1 a_1 = \alpha_1,\ B_1 b_1 = \beta_1,\ C_1 c_1 = \gamma_1$$
$$A_2 a_2 = \alpha_2,\ B_2 b_2 = \beta_2,\ C_2 c_2 = \gamma_2$$
$$A_3 a_3 = \alpha_3,\ B_3 b_3 = \beta_3,\ C_3 c_3 = \gamma_3$$

We may then imagine a surface of the form (1.) to pass through the nine points, $a_1, a_2, a_3, b_1, b_2, b_3, c_1, c_2, c_3$.

$$z = A + Bx + Cx^2 + B_1 y + C_1 y^2 + Dxy + Ex^2 y + Exy^2 + Cx^2 y^2 \quad \ldots\ldots \quad \text{(I.)}$$

Calculations incidental to designing a Ship.

Since it contains *nine* arbitrary constants, A, B, C, B_1, C_1, &c., observing that the xs are measured along $A_1 A_3$, the ys along $A_1 C_1$, and the zs are $A_1 \alpha_1$, $A_2 \alpha_2$, $A_3 \alpha_3$, $B_1 b_1$, &c. Hence we have the following equations:—

(1.) $\alpha_1 = A$..............when $x=0,\ y=0, z=\alpha_1$...by (I.)

(2.) $\alpha_2-\alpha_1 = Bh + Ch^2$........ $x=h,\ y=0, z=A_2\alpha_2=\alpha_2$

(3.) $\alpha_3-\alpha_1 = 2Bh+4Ch^2$....... $x=2h, y=0, z=A_3\alpha_3=\alpha_3$

(4.) $\beta_1-\alpha_1 = B_1k + C_1k^2$....... $x=0,\ y=k, z=B_1 b_1=\beta_1$

(5.) $\gamma_1-\alpha_1 = 2B_1k+4C_1k^2$...... $x=0,\ y=2k, z=C_1 c_1=\gamma_1$

(6.) $\beta_2-\alpha_2-\beta_1+\alpha_1 = Dhk + Eh^2k + Ehk^2 + Gh^2k^2$...by (2.) and (4.)................................ $x=h,\ y=k,\ z=B_2b_2=\beta_2$

(7.) $\beta_3-\alpha_3-\beta_1+\alpha_1 = 2Dhk + 4Eh^2k + 2Ehk^2 + 4Gh^2k^2$...by (3.) and (4.)........ .... $x=2h, y=k,\ z=B_3 b_3=\beta_3$

(8.) $\gamma_2-\alpha_2-\gamma_1+\alpha_1 = 2Dhk + 2Eh^2k + 4Ehk^2 + 4Gh^2k^2$...by (2.) and (5.)......................... $x=h,\ y=2k, z=C_2 c_2=\gamma_2$

(9.) $\gamma_3-\alpha_3-\gamma_1+\alpha_1 = 4Dhk + 8Eh^2k + 8Ehk^2 + 16Gh^2k^2$...by (3.) and (5.)....................... $x=2h, y=2k, z=C_3c_3=\gamma_3$

Now, B, C, B_1 and C_1 are readily determined from equations (2), (3), (4), and (5), and D, E, F, and G, from equations (6), (7), (8), and (9); their values are—

$$A = \alpha_1$$

$$B = \frac{4\alpha_2-3\alpha_1-\alpha_3}{2h}.$$

$$C = \frac{\alpha_1-2\alpha_2+\alpha_3}{2h^2}.$$

$$B_1 = \frac{4\beta_1-3\alpha_1-\gamma_1}{2k}.$$

$$C_1 = \frac{\alpha_1-2\beta_1+\gamma_1}{2k^2}.$$

$$D = \frac{16\beta_2+9\alpha_1+3\alpha_3+3\gamma_1+\gamma_3-12\alpha_2-12\beta_1-4\beta_3-4\gamma_2}{4hk}.$$

$$E = \frac{6\alpha_2+4\beta_1+4\beta_3+2\gamma_2-3\alpha_1-3\alpha_3-8\beta_2-\gamma_1-\gamma_3}{4h^2k}.$$

$$F = \frac{4\alpha_2+6\beta_1+2\beta_3+4\gamma_2-3\alpha_1-\alpha_3-8\beta_2-3\gamma_1-\gamma_3}{4hk^2}.$$

$$G = \frac{\alpha_1+\alpha_3+4\beta_2+\gamma_1+\gamma_3-2\alpha_2-2\beta_1-2\gamma_2-2\beta_3}{4h^2k^2}.$$

In order to find the volume of a solid, we must integrate the equation $\iiint dx\,dy\,dz$, as shown in most works on the Differential and Integral Calculus, or, what amounts to the same thing, $\iint z\,dx\,dy$, where z is given by the equation to the surface, and the integrations in regard to x and y are to be determined by the conditions of the question. It is evident that, in the present case, the limiting values of x are 0 and $2h$, those of y being 0 and $2k$. Hence

$$\int_0^{2h}\int_0^{2k} z\,dxdy = \int_0^{2h}\int_0^{2k} dx\,dy\,(A + Bx + Cx^2 + B_1y + C_1y^2 + Dxy + Ex^2y + Exy^2 + Gx^2y^2) = \frac{hk}{9}\Big\{36A + 36Bh + 48Ch^2 + 36B_1h + 48C_1k^2 + 36Dhk + 48Eh^2k + 48Ehk^2 + 64Gh^2k^2\Big\}.$$

Introducing the values of A, B, C, &c. already found, we get, after obvious reductions, volume $A_1c_3 = \frac{hk}{9}\Big\{\alpha_1+4\alpha_2+\alpha_3 + 4(\beta_1+4\beta_2+\beta_3)+\gamma_1+4\gamma_2+\gamma_3\Big\}$ . . . . . (II.)

On examining the equations, we perceive that $\frac{h}{3}(\alpha_1+4\beta_2+\alpha_3)$ represents the area of the section $A_1\alpha_3$ (*Vide* Equation I., p. 141), and $\frac{h}{3}(\beta_1+4\beta_2+\beta_3)$ represents the area B_1b_3; also, $\frac{h}{3}(\gamma_1+4\gamma_2+\gamma_3)$ that of C_1c_3. Writing for the area of $A_1\alpha_3$, A_1; for that of B_1b_3, A_2; for C_1c_3, A_3 (Equation II.) becomes

$$\text{Volume } A_1c_3 = \frac{k}{3}(A_1+4A_2+A_3) \quad . \ . \ . \ . \ . \ . \ . \quad \text{(III.)}$$

By making similar paraboloidal surfaces pass through c_1, c_2, c_3, and six other points, &c. we have

$$\text{Volume } A_3c_5 \text{ next portion} = \frac{k}{3}(A_3+4A_4+A_5).$$

$$\text{"} \qquad \text{"} \qquad = \frac{k}{3}(A_5+4A_6+A_7).$$

$$\text{" last portion} = \frac{k}{3}(A_{n-2}+4A_{n-1}+A_n).$$

Adding these—

$$\text{Total volume} = \frac{k}{3}\Big\{A_1+A_n+4(A_2+A_4+A_6+\&c.+A_{n-1}+2(A_3+A_5+\&c.+A_{n-2})\Big\} \quad . \ . \ . \ . \ . \ . \quad \text{(IV.)}$$

We might have regarded $\frac{k}{3}(\alpha_1+4\beta_1+\gamma_1)$ as the area of the section A_1c_1, or B_1, as we shall denote it, $\frac{k}{3}(\alpha_2+4\beta_2+\gamma_2)$ that of A_2c_2, &c., or B_2, &c., and then

Volume $= \frac{h}{3}\Big\{B_1+B_n+4(B_2+B_4+\&c.+B_{n-1})+2(B_3+B_5+\&c.\ B_{n-2})\Big\}$. Multiplying these volumes by 2, we get the total displacement of the ship.

A Rule similar to that of (II.) Note (2) may be found by making a surface, the equation to which is of the form $z = A + Bx + Cx^2 + Dx^3 + B_1y + C_1y^2 + D_1y^3 + Exy + Ex^2y + Gxy^2 + Hx^2y^2 + Ix^3y + Kxy^3 + Lx^3y^2 + Mx^2y^3 + Nx^3y^3$ pass through sixteen points, since the equation contains this number of arbitrary constants, which are determined as before, and the integrations are taken from $x=0$ to $x=3h$, and $y=0$ to $y=3k$. We shall leave this work for the student, and proceed at once to

Observe that *vertical* areas may be employed in the place of *horizontal* areas, and care must be taken to omit the first and last areas from the *odd* ones in each case.

Rule (II.) might have been employed; but the following is the neatest, most concise, and at the same time sufficiently accurate, that has yet been given. It is by the Rev. Joseph Woolley, M.A., LL.D., Her Majesty's Inspector of Schools, to whom naval architects are under great obligations for the attention he has given to this branch of science:—

RULE V. (1.) *Add together all the* EVEN *ordinates in the* FIRST *and* LAST *horizontal planes.*

(2.) *Add together all the* EVEN *ordinates in the 3d, 5th, 7th, &c., sections, omitting the* FIRST *and* LAST, *and multiply the sum by 2.*

(3.) *Add together all the* FIRST *and* LAST *ordinates of all the* EVEN *horizontal planes.*

(4.). *Take* TWICE *the sum of all the ordinates, omitting the* FIRST *and* LAST *of all the* EVEN *horizontal planes.*

Then, *add together the results of (1), (2), (3), (4), and multiply this final sum by* TWO-THIRDS *of the product of the common distances between the horizontal and vertical planes, and this result gives the displacement.*

Note 5.—Not having seen the demonstration by Dr Woolley to this rule, the editors beg to offer the following, which must be somewhat similar in principle.

Dr Woolley supposes fig. 4 to be divided into two portions by a plane passing through $C_1 B_2 A_3 a_3 b_2 c_1$, and the equation to the surface passing through $a_1 b_1 c_1 b_2 a_2 a_3$ may be assumed as

$$z = A + Bx + Cx^2 + B_1y + C_1y^2 + Dxy \quad . \ . \ . \ . \quad \text{(I.)}$$

And the limits are $x=0$ and $x=2h$, and since, $A_1C_1 = 2k$, at any point y, we must have $y = \left(\frac{2h-x}{h}\right)k$.

$$\therefore \int_0^{2h}\int_0^{(2h-x)\frac{k}{h}} z\,dxdy = \int_0^{2h}\int_0^{(2h-x)\frac{k}{h}} dxdy(A + Bx + Cx^2 + B_1y + C_1y^2 + Dxy).$$

Calculations incidental to designing a Ship.

$$= \int_0^{2h} dx \left\{ A\left(\frac{2h-x}{h}\right)k + Bkx\left(\frac{2h-x}{h}\right) + Ckx^2\left(\frac{2h-x}{h}\right) + \frac{B_1k^2}{2}\left(\frac{4h^2-4hx+x^2}{h}\right) + \frac{C_1k^3}{3}\left(\frac{8h^3-12h^2x+6hx^2-x^3}{h^3}\right) + \frac{Dk^2x}{2}\left(\frac{4h^2-4hx+x^2}{h}\right)\right\}$$

$$= 2Ahk + \frac{4Bh^2k}{3} + \frac{4Ch^3k}{3} + \frac{4B_1hk^2}{3} + \frac{4C_1hk^3}{3} + \frac{2Dh^2k^2}{3} \quad \text{(II.)}$$

Now, since the surface (I.) passes through the six points already mentioned, we readily determine A, B, C_1, &c., as in the last note Their values are

$$\begin{aligned} A &= \alpha_1 \\ 2Bh &= 4\alpha_2 - \alpha_3 - 3\alpha_1 \\ 2Ch^2 &= \alpha_1 - 2\alpha_2 + \alpha_3 \\ 2B_1k &= 4\beta_1 - \gamma_1 - 3\alpha_1 \\ 2C_1k^2 &= \alpha_1 - 2\beta_1 + \gamma_1 \\ Dhk &= \alpha_1 + \beta_1 - \alpha_2 - \beta_1 \end{aligned}$$

Writing these values in (II.) it reduces to

$$\text{Volume} = \frac{2hk}{3}\left\{\alpha_2 + \beta_1 + \beta_2\right\}$$

In the same way, we find the volume of the figure $C_1\, c_1\, b_2\, a_3\, C_3$

$$= \frac{2hk}{3}\left\{\gamma_2 + \beta_3 + \beta_2\right\}$$

Adding these results, we find for the whole volume $A_1\, c_3$

$$\frac{2hk}{3}\left\{\alpha_2 + \beta_1 + 2\beta_2 + \beta_3 + \gamma_2\right\}$$

With similar expressions for the other portions of the ship.

$$\therefore \text{Whole volume} = \frac{2hk}{3}\left\{\beta_1 + \beta_n + 2(\beta_3 + \beta_5 + \beta_7 + \&c.) + (\alpha_2 + \gamma_2 + \alpha_4 + \gamma_4 + \&c.) + 2(\beta_2 + \beta_4 + \beta_6 + \beta_8 + \&c.\right\}$$

To find the Centres of Gravity of Bodies.

ART. 3. As a knowledge of the centres of gravity of bodies is of so much importance in the calculation of stability, it has been thought advisable to introduce the subject here at some length.

Various definitions have been given of the centre of gravity of a body. It is shown in almost every work on statics, that *there is a point in* (sometimes *without*) *every body such, that if the particles of the body be acted on by parallel forces, and the point already mentioned be fixed or supported, the body will remain in equilibrium, no matter in what position it is placed;*[1] and when the *forces* herein mentioned are replaced by the *weights* of the elementary portions of the body, or bodies, this point is known as the *centre of gravity* of the body or bodies.[2]

Gravity, or the force which attracts all bodies towards the earth's centre, is supposed to act on every particle of the body in parallel and vertical directions. This force is supposed to be constant at the earth's surface, and therefore attracts all bodies with an equal intensity. The reader will readily perceive that this hypothesis cannot differ materially from the truth when he compares the earth's radius with the dimensions of all bodies at its surface, and remembers that this attractive force varies inversely as the square of the distance. Under these circumstances, then, the centres of gravity of bodies are calculated. This point cannot be obtained, however, without the aid of the integral calculus, except in the case of a few plane surfaces and solids. We shall premise that when bodies are *homogeneous*, or of the same density throughout their parts,—that is, having equal weights, comprised under equal volumes,—we may then replace *weights* by *masses*, and conversely. Thus if M represent the mass of a body, d the density of a unit of the body, V the volume, W the weight, then

$$M = d \times V \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1.)$$
$$W = g \times d \times V = gM \quad . \quad . \quad . \quad . \quad . \quad (2.)$$[3]

When a body is not homogeneous throughout its parts, the determination of the centre of gravity becomes somewhat more difficult.

To find the Centre of Gravity of an Area similar to fig. 1.

Centre of gravity.

ART. 4.—RULE VI. *Multiply the ordinates, beginning at the first by* 0, 1, 2, 3, 4, *&c., respectively, and employ these as ordinates in Rule (I.); multiply the result thus obtained by one-third of the common interval squared, divide by the area of the curve, and the result gives the distance we are to measure along* $A_1\,A_n$—*i.e.*, $A_1\,g$.[4]

Having obtained the distance A_1g, we may obtain the length of the perpendicular Gg (G being the centre of gravity of the figure, and g the point where the perpendicular drawn from G intersects A_1A^n.) by

RULE VII. *To the sum of the* SQUARES *of the* FIRST *and* LAST *ordinates, add* FOUR *times the sum of the squares of all the* EVEN *ordinates, twice the sum of the squares of all the* ODD *ordinates; multiply by one-third the common interval, and divide this result by twice the area, the quotient gives the perpendicular height of the centre of gravity above the axis* $A_1\,A_n$.[5]

Similar rules apply for finding the centres of gravity of the displacement of a ship.

ART. 5. *To find the centre of gravity of the displacement of a ship floating in the water, and in a state of equilibrium*—

The horizontal sections are taken at equal distances apart and parallel to the plane of flotation. The vertical sections are also taken at equal distances apart and parallel to the midship section. The ship is then cut into two equal portions by a plane running fore and aft, and at right angles to the two planes just mentioned. In the following rules, *half areas* and *half volumes* are to be understood.

RULE VIII. *Find the areas of all the horizontal sections (such as those shown in the half-breadth plan) and multiply these, beginning from the first, or plane of flotation, by the consecutive numbers* 0, 1, 2, 3, 4, *&c., respectively; introduce these products as ordinates into "Simpson's Rule;" multiply this result by one-third of the square of common distance between the sections, divide by the volume, and the quotient gives the distance of the centre of gravity below the plane of flotation.*[4]

RULE IX. *Find the areas of all the vertical sections, multiply these, beginning from the first*[6] *by the consecutive numbers* 0, 1, 2, 3, 4, *&c., respectively, and work as in the last rule; the result thus obtained gives the distance of the centre of gravity from the first vertical plane.*

[1] Pratt's *Mechanical Philosophy*, 2d edit., pp. 18 and 19.

[2] *The centre of gravity* has also been defined as that point within or without the body, from which, if the body be conceived to be suspended, it will remain in equilibrium in any position.

[3] "g, or 'the accelerating force of gravity,' is uniform, and is the same for all substances, and in the latitude of London = 32·18 feet." (Earnshaw's *Dynamics*, 3d edit., p. 42.)

[4] Care must be taken *not* to multiply by one-third of the common distance, as is mentioned in Rule I.

[5] The *last* ordinate must not be reckoned among the *odd* ordinates in these and the following rules.

[6] Either the first vertical section of the main body nearest the bow or stern may be taken as the first.

Calculations incidental to designing a Ship.

Centre of gravity.

These two distances fix the position of the centre of gravity of the main body. Since a ship is symmetrical in regard to the plane which divides it, fore and aft, into two equal parts, we know that the centre of gravity must lie in this plane.

No account is here taken of the small portions at the stem, stern, and that between the keel and last horizontal section. These are usually calculated separately, and in the same way as the main body. Having obtained the centres of gravity of all these portions, we readily obtain the centre of gravity of the total displacement by the rule which follows, observing, that if we consider the *first vertical plane* to be that nearest the bow, the volume of the small portion forward multiplied by the distance of its centre of gravity from the plane just mentioned must be *subtracted*. Or, in other words, if we consider all horizontal distances, measured in the *opposite* direction (from the first vertical plane) to the centre of gravity of the main body as *negative*, and all distances measured in the *same direction* as *positive*, we have then only to add the products *algebraically*, and this is to be understood in the following rule (one product being always *negative* in Rule XI.) All *results will be positive* in finding the distance of the centre of gravity *below the plane of flotation.*

RULE X. *Multiply each of the volumes by the perpendicular distance of its centre of gravity from the plane of flotation, and add the products; divide this result by the sum of all the volumes, and the quotient is the distance of the centre of gravity of the total displacement below the plane of flotation.* Also,

RULE XI. *Multiply each of the volumes by the perpendicular distance of its centre of gravity from the first vertical plane, and add algebraically (observing that one result will be negative), divide this result by the sum of all the volumes, and the quotient is the distance of the centre of gravity of the total displacement from the first vertical plane.*

One of the properties of Guldinus is also of great use in finding centres of gravity when the necessary data are supplied.

RULE XII. *Any solid of revolution is equal to the area of the surface which generates this solid, multiplied by the circumference, which is described by the centre of gravity of the latter.*

Without attempting to demonstrate formulæ (1.) of this article, since a demonstration may be found in almost every work on statics, we proceed to lay before the mathematical reader the principles on which the centres of gravity are calculated.

Note 6.—If we consider, in the first place, a system of material points having weight, and connected in an invariable manner, the weights of these points may be considered as so many vertical forces acting in parallel directions. If, moreover, we take three fixed planes, mutually at right angles to each other, their point of intersection being the origin (as is done in Geometry of three dimensions) let ω_1 be the weight of the first material point, and its co-ordinates x_1, y_1, z_1, measured along the three co-ordinate axes: ω_2, x_2, y_2, z_2, the weight and co-ordinates of the second point, &c. &c.; also, let $\bar{x}$, $\bar{y}$, $\bar{z}$ represent the co-ordinates of the centre of gravity of the system of weights measured along the same axes, then we have

$$\left.\begin{aligned}\bar{x} &= \frac{\Sigma(\omega_1 x_1 + \omega_2 x_2 + \omega_3 x_3 + \&c.)}{\Sigma(\omega_1 + \omega_2 + \omega_3 + \&c.\ \&c.)}\\ \bar{y} &= \frac{\Sigma(\omega_1 y_1 + \omega_2 y_2 + \omega_3 y_3 + \&c.)}{\Sigma(\omega_1 + \omega_2 + \omega_3 + \&c.)}\\ \bar{z} &= \frac{\Sigma(\omega_1 z_1 + \omega_2 z_2 + \omega_3 z_3 + \&c.)}{\Sigma(\omega_1 + \omega_2 + \omega_3 + \&c.)}\end{aligned}\right\} \quad . \; . \; . \; . \; . \quad (1.)$$

Remark.—These formulæ would be equally true if we suppose ω_1, ω_2, ω_3, &c. to represent the weights of any bodies whatever, and connected in an invariable manner, *providing we suppose these weights to act at their respective centres of gravity, and* x_1, y_1, z_1, *&c., to be the co-ordinates of these centres of gravity.* Next, if we suppose the density of the weights to be uniform throughout, we can replace the weights by their respective volumes v_1, v_2, v_3, &c. since $g \times d$ appears both in numerator and denominator. The proposition is also true for areas. Therefore, if A_1, A_2, A_3, &c. represent areas

$$\left.\begin{aligned}\bar{x} &= \frac{\Sigma(v_1 x_1 + v_2 x_2 + v_3 x_3 + \&c.)}{\Sigma(v_1 + v_2 + v_3 + \&c.)},\\ \text{or } \bar{x} &= \frac{\Sigma(A_1 x_1 + A_2 x_2 + A_3 x_3 + \&c.)}{\Sigma(A_1 + A_2 + A_3 + \&c.)}\\ \bar{y} &= \frac{\Sigma(v_1 y_1 + v_2 y_2 + v_3 y_3 + \&c.)}{\Sigma(v_1 + v_2 + v_3 + \&c.)},\\ \text{or } \bar{y} &= \frac{\Sigma(A_1 y_1 + A_2 y_2 + A_3 y_3 + \&c.)}{\Sigma(A_1 + A_2 + A_3 + \&c.)}\\ \bar{z} &= \frac{\Sigma(v_1 z_1 + v_2 z_2 + v_3 z_3 + \&c.)}{\Sigma(v_1 + v_2 + v_3 + \&c.)}\\ \text{or } \bar{z} &= \frac{\Sigma(A_1 z_1 + A_2 z_2 + A_3 z_3 + \&c.)}{\Sigma(A_1 + A_2 + A_3 + \&c.)}\end{aligned}\right\} \quad . \; . \; . \; . \quad (2.)$$

If the centres of gravity of the weights, volumes, or areas, as the case may be, range in a right line, the first equation gives the distance of their common centre of gravity from the origin. If the weights, or areas, &c., are in the same plane, the four former equations are all that are necessary to determine the centre of gravity.

Premising that the centre of gravity of a ball, or sphere, is at the centre of the body, we shall proceed to give two or three examples on these formulæ.

(1.) Four cannon-balls have their centres in the same right line at 2, 3, and 4 feet, respectively, apart, and weigh 68, 32, 12, and 8 lbs. respectively; that is, the "32" is 2 feet from the "68," the "12" is 3 feet from the "32," &c. Find the distance of the common centre of gravity from the centre of the "68" (supposing their centres to be in the same horizontal line).

Taking the origin at the centre of the "68," we have $x_1 = 0$, $x_2 = 2$, $x_3 = 2 + 3 = 5$, $x_4 = 2 + 3 + 4 = 9$ feet.

$$\therefore \text{ (1.) } \bar{x} = \frac{68 \times 0 + 32 \times 2 + 12 \times 5 + 8 \times 9}{68 + 32 + 12 + 8} = 1\cdot6\dot{3} \text{ feet.}$$

That is, if the balls were connected by an indefinitely fine rigid rod, without weight, passing through the centres of the balls, the whole might be suspended, and remain in equilibrium, at a point distant 1·63 feet from the centre of the "68."

(2.) Five cannon-balls, whose weights are 2, 8, 12, 32, and 68 lbs., lie on the floor of a room, at the respective perpendicular distances 3, 4, 5, 6, and 7 feet from the side, and 1, 2, 3, 4, and 5 feet from one end of the room; find their common centre of gravity from that corner of the room where the side and end (from which these distances are measured) intersect, supposing the centres of the balls to lie in the plane of the floor.

$$\text{Here } \bar{x} = \frac{2 \times 3 + 8 \times 4 + 12 \times 5 + 32 \times 6 + 68 \times 7}{2 + 8 + 12 + 32 + 68} =$$

6·28 feet nearly.

$$\bar{y} = \frac{2 \times 1 + 8 \times 2 + 12 \times 3 + 32 \times 4 \times 68 \times 5}{2 + 8 + 12 + 32 + 68} =$$

4·28 feet nearly.

$$\text{But distance from corner} = \sqrt{\bar{x}^2 + \bar{y}^2}$$

$$= \sqrt{(6\cdot28)^2 + (4\cdot28)^2} =$$

7·6 feet nearly.

(3.) Four cannon-balls, whose weights are 1, 8, 32, and 68 lbs., are suspended in a room (of the form of a parallelopipedon), their vertical heights from the floor being 2, 4, 6, and 5 feet, respectively, and their perpendicular distances, from an end and side of the room, are 2, 4, 5, 6 feet, and 3, 5, 6, 7 feet, respectively; find the distance of the centre of gravity of the balls, from that corner of the room where the side and end, herein mentioned, intersect.

Calculations incidental to designing a Ship.

Here the side, end, and floor of the room are the planes of reference, and the origin at the corner, mentioned in the question, the line where the *side* intersects the floor may be taken as the axis of x, and the intersection of the *end* and floor as the axis of y, or, *vice versâ*, the intersections of the end and side being the axis of z.

$$\therefore \bar{x} = \frac{1 \times 2 + 8 \times 4 + 5 \times 32 + 6 \times 68}{1 + 8 + 32 + 68} = 5{\cdot}523 \text{ ft. nearly.}$$

$$\bar{y} = \frac{1 \times 3 + 8 \times 5 + 32 \times 6 + 68 \times 7}{1 + 8 + 32 + 68} = 6{\cdot}523 \quad ,,$$

$$\bar{z} = \frac{1 \times 2 + 8 \times 4 + 32 \times 6 + 68 \times 5}{1 + 8 + 32 + 68} = 5{\cdot}192 \quad ,,$$

Again, it is easily shown that the distance of a point $\bar{x}, \bar{y}, \bar{z}$, from the origin is—

$$d = \sqrt{\bar{x}^2 + \bar{y}^2 + \bar{z}^2} = \sqrt{(5{\cdot}523)^2 + (6{\cdot}523)^2 + (5{\cdot}192)^2} =$$
10 feet nearly.

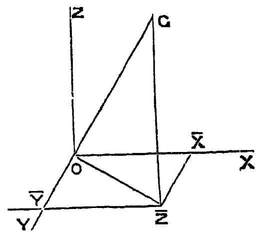

Fig. 5.

For if XOY be the plane of the floor, XOZ the side, and YOZ the end of the room, G the centre of gravity. Draw $G\bar{Z} \perp$ to the plane XOY; and from $\bar{Z}$ draw $\bar{Z}\bar{X}$ and $\bar{Z}\bar{Y}$ respectively, $\perp$ to OX and OY; then $O\bar{X} = \bar{x}$, $O\bar{Y} = \bar{y}$, $G\bar{Z} = \bar{z}$ in the above equations, and since the triangles $O\bar{X}\bar{Z}$, $O\bar{Z}G$ are right-angled,

$$OG^2 = O\bar{Z}^2 + G\bar{Z}^2 = O\bar{X}^2 + \bar{X}\bar{Z}^2 + G\bar{Z}^2, \text{ and } \bar{X}\bar{Z}^2 = O\bar{Y}^2.$$

$$\therefore OG = \sqrt{O\bar{X}^2 + O\bar{Y}^2 + G\bar{Z}^2}$$

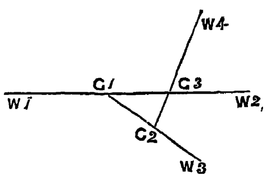

Fig. 6.

We might have determined the centre of gravity of any system of material points, or balls, not situated in the same line, or plane, and rigidly connected in the following manner: W_1, W_2, W_3, &c. representing these material points and their positions, join $W_1 W_2$, and let G_1 be their common centre of gravity, then these two points will act in the same manner as if their weights were collected at the point G_1. Join $G_1 W_3$, and let G_2 be the centre of gravity of W_1, W_2, acting at G_1, and of W_3; then W_1, W_2, W_3, may be conceived to act at G_2. Join $G_2 W_4$, &c. &c.

Note 7.—The principles made use of in equations (1.) may readily be extended to any body, or system of bodies; for, suppose the body referred to three co-ordinate planes mutually at right angles to each other, their common point of intersection being the origin, and x_1, y_1, z_1, the co-ordinates of any point in the body; then it is shown, in most works on the "Calculus," that the *volume* of an infinitesimal parallelopipedon, at that point, is represented by $\Delta x_1 \times \Delta y_1 \times \Delta z_1$.[1] Also, if δ_1 represents the density of a unit of volume at that point, the mass of the particle is $\delta_1 . \Delta x_1 . \Delta y_1 . \Delta z_1$, and its weight is $g\delta_1 \, \Delta x_1 \, \Delta y_1 \, \Delta z_1$. But as g is constant, it follows that we may either employ the weights or masses of the body in finding its centre of gravity, and

$$M = \Sigma\,(\delta_1 \, \Delta x_1 . \Delta y_1 . \Delta z_2 + \delta_2 + \Delta x_2 \, \Delta y_2 \, \Delta z_2 + \text{\&c. \&c.})$$

$$\bar{x} = \frac{\Sigma\,(x_1 \, \delta_1 \, \Delta x_1 \, \Delta y_1 \, \Delta z_2 + x_2 \, \delta_2 \, \Delta_2 x_2 \, \Delta y_2 \, \Delta z_2 + \text{\&c.})}{M}$$

$$\bar{y} = \frac{\Sigma\,(y_1 \, \delta_1 \, \Delta x_1 \, \Delta y_1 \, \Delta z_1 + y_2 \, \delta_2 \, \Delta x_2 \, \Delta y_2 \, \Delta z_2 + \text{\&c.})}{M}$$

$$\bar{z} = \frac{\Sigma\,(z_1 \, \delta_1 \, \Delta x_1 \, \Delta y_1 \, \Delta z_1 + z_2 \, \delta_2 \, \Delta x_2 \, \Delta y_2 \, \Delta z_2 + \text{\&c.})}{M}$$

But at the limit Δx_1, Δy_1, Δz_1 become dx_1, dy_1, dz_1, and dropping the suffixes, and extending the summation, or rather integration, to all the elements of the body, we obtain

$$(1.) \qquad M = \int\!\!\int\!\!\int dx \, dy \, dz \, . \, \delta.$$

Where δ is given by an equation of the form $\delta = f\,(x, y, z)$.

$$\text{Hence } \bar{x} = \frac{\int\!\!\int\!\!\int x \, dx \, dy \, dz \, . \, \delta}{M}, \; \bar{y} = \frac{\int\!\!\int\!\!\int y \, dx \, dy \, dz \; \delta}{M}, \; \bar{z} = \frac{\int\!\!\int\!\!\int z \, dx \, dy \, dz \; \delta}{M}.$$

These equations are to be taken between proper limits, and if the body is homogeneous, δ will appear in both numerators and denominators, and the equations may then be written:

$$(2.) \begin{cases} V = \int\!\!\int\!\!\int dx \, dy \, dz. \\ \bar{x} = \dfrac{\int\!\!\int\!\!\int x \, dx \, dy \, dz}{V}, \; \bar{y} = \dfrac{\int\!\!\int\!\!\int y \, dx \, dy \, dz}{V}, \; \bar{z} = \dfrac{\int\!\!\int\!\!\int z \, dx \, dy \, dz}{V}. \end{cases}$$

We may obtain a clearer idea of these integrals from the following considerations. Let us take the first of the latter set of equations, and integrate, first, in regard to z, and next in regard to y, observing that in these integrations x is constant, we may then write

$$\bar{x} = \int \left\{ \frac{x \int\!\!\int dy \, dz}{V} \right\} dx.$$

Where the quantity within the brackets represents the product of x by the *area*, A, of a plane section of the figure, perpendicular to the axis of x, and at a distance x from the plane of zy.

$\therefore \bar{x} = \dfrac{\int A \, x dx}{V}$, and similar expressions may be obtained for $\bar{y}$

If it be required to find the centre of gravity of *any* area, &c. we have only to suppose it to lie in the plane of xy and formulæ (2) reduce to

$$(3.) \begin{cases} A = \int\!\!\int dx \, dy = \int y \, dx \text{ (if we integrate in regard to } y) \\ \bar{x} = \dfrac{\int\!\!\int x \, dx \, dy}{A} = \dfrac{\int xy \, dx}{A}, \; \bar{y} = \dfrac{\int\!\!\int y \, dx \, dy}{A} = \frac{1}{2} \dfrac{\int y^2 \, dx}{A}. \end{cases}$$

Remark.—In many cases it is convenient to employ *polar co-ordinates* to find centres of gravity, and we have for the transformation

$$x = r \sin \theta \cos \phi, \; y = r \sin \theta \sin \phi, \; z = r \cos \theta,$$

Formulæ (2.) become

$$(4.) \begin{cases} \bar{x} = \dfrac{\int\!\!\int\!\!\int r^3 \sin{}^2\theta \cos \phi \, dr . d\theta . d\phi}{\int\!\!\int\!\!\int r^2 \sin \theta \, dr . d\theta . d\phi}, \\ \bar{y} = \dfrac{\int\!\!\int\!\!\int r^3 \sin{}^2\theta \sin \phi \, dr \, d\theta \, d\phi}{\int\!\!\int\!\!\int r^2 \sin \theta \, dr \, d\theta \, d\phi}, \\ \bar{z} = \dfrac{\int\!\!\int\!\!\int r^3 \sin \theta \cos \theta \, dr \, d\theta \, d\phi}{\int\!\!\int\!\!\int r^2 \sin \theta \, dr \, d\theta \, d\phi}, \end{cases}$$

where $\int\!\!\int\!\!\int r^2 \sin \theta \, dr \, d\theta \, d\phi$ between proper limits gives the volume.

We shall at once proceed to show by formulæ (3.) how to find the centre of gravity of an area, similar to the horizontal or vertical sections of a ship, premising that the notation is the same as that employed above (p. 140).

Note 8.—To find the centre of gravity of the portion $A_1 \alpha_3$, the equation to the parabola passing through α_1, α_2, α_3, being (h the common interval).

$$y = A + B\,x + Cx^2, \; x1 \text{ denoting } A_1 \, g_1 \text{ and } \bar{y}_1, \; G_1 \, g_1.$$

$$\bar{x}_1 = \frac{\int xy \, dx}{\int y \, dv} = \frac{\int_0^{2h} x\,(A + Bx + Cx^2)\,dx}{\int_0^{2h} (A + Bx + Cx^2)\,dx}$$

$$= \frac{\dfrac{h^2}{3}\left\{6A + 8Bh + 12Ch^2\right\}}{\dfrac{h}{3}\left\{6A + 6Bh + 8Ch^2\right\}} = h\left\{\frac{6A + 8Bh + 12Ch^2}{6A + 6Bh + 8Ch^2}\right\}.$$

But by Note (1), formulæ (2, 5, and 6) $A = \alpha_1$, $B = \dfrac{4\alpha_2 - \alpha_3 - 3\alpha_1}{2h}$, and $C = \dfrac{\alpha_3 - 2\alpha_2 + \alpha_1}{2h^2}$. Writing these in the above, we get

$$\bar{x}_1 = \frac{2h\,(2\alpha_2 + \alpha_3)}{\alpha_1 + \alpha_3 + 4\alpha_2}.$$

In the same way, the centre of gravity of $A_3 \, A_5$, along the line $A_1 \, A_n$ is found to be

$$A_3 g_2 = \frac{2h\,(2\alpha_4 + \alpha_5)}{\alpha_3 + \alpha_5 + 4\alpha_4}. \quad \therefore \; A_1 \, g_2 = A_1 \, A_3 + A_3 \, g_2 = 2h +$$

[1] Δx_1, Δy_1, Δz_1, represent the respective increments of x_1, y_1, z_1.

$\frac{2h(\alpha_4 + \alpha_5)}{\alpha_3 + \alpha_5 + 4\alpha_4}$, or if $\bar{x}_2 = A_1 g_2$, $\bar{x}_3 = A_2 g_3$, &c.

$$\bar{x}_2 = 2h + \frac{2h(2\alpha_4 + \alpha_5)}{\alpha_3 + \alpha_5 + 4\alpha_4} = \frac{2h(\alpha_3 + 6\alpha_4 + 2\alpha_5)}{\alpha_3 + \alpha_5 + 4\alpha_4}.$$

$$\bar{x}_3 = 4h + \frac{2h(2\alpha_6 + \alpha_7)}{\alpha_5 + \alpha_7 + 4\alpha_6} = \frac{2h(2\alpha_5 + 10\alpha_6 + 3\alpha_7)}{\alpha_5 + \alpha_7 + 4\alpha_6}.$$

And if g be the distance along the line $A_1 A_n$ of the centre of gravity of the whole figure, we have by formula (2), since the areas may be supposed to be collected at their respective centres of gravity, G_1, G_2, G_3, &c.

$$Ag \text{ or } \bar{x} = \frac{\text{Area } A_1 a_3 \times Ag_1 + \text{area } A_3 a_5 \times A_1 g_2 + \text{area } A_5 a_7 \times A_1 g_3 + \&\text{c. }\&\text{c.}}{\text{Area } A_1 a_3 + \text{area } A_3 a_5 + \text{area } A_5 a_7 + \&\text{c. }\&\text{c.}}$$

$$= \frac{A_1 \bar{x}_1 + A_2 \bar{x}_2 + A_3 \bar{x}_3 + \&\text{c.} + A_n \bar{x}_n}{A_1 + A_2 + A_3 + \&\text{c.} + A_n}.$$

Introducing the values of A_1, A_2, A_3, &c. $\bar{x}_1$, $\bar{x}_2$, $\bar{x}_3$, &c. already found, this reduces to

$$\text{(I.)}\ \bar{x} = h\,\frac{\{0 + (n-1)\alpha_n + 4(\alpha_2 + 3\alpha_4 + 5\alpha_6 + 7\alpha_8 + \&\text{c.}) + 2(2\alpha_3 + 4\alpha_5 + 6\alpha_7 + \&\text{c.})\}}{\alpha_1 + \alpha_n + 4(\alpha_2 + \alpha_4 + \alpha_6 + \alpha_8 + \&\text{c.}) + 2(\alpha_3 + \alpha_5 + \alpha_7 + \&\text{c.})}.$$

Next, to find Gg, or $\bar{y}$, we have

$$\bar{y}_1 = \tfrac{1}{2}\frac{\int_0^{2h} y^2\,dx}{\int_0^{2h} y\,dx},\quad \bar{y}_2 = \tfrac{1}{2}\frac{\int_0^{2h} y^2\,dx}{\int_0^{2h} y\,dx}, \text{ \&c. \&c.}$$

But $y^2 = (A + Bx + Cx^2)^2$; and this integration, added to the work connected with the substitution into the form

$$\bar{y} = \frac{A_1 \bar{y}_1 + A_2 \bar{y}_2 + \&\text{c.}}{A_1 + A_2 + \&\text{c.}}.$$

would lead to an immense amount of labour, which may be avoided by observing that the integral $\int y^2\,dx$ may be taken to represent the *area* of a curve, the ordinates of which are the squares of those at given points of the curve, as α_1, α_2, α_3, &c. With this understanding, we readily find, by employing "Simpson's Rule,"

$$\text{(II)}\ \bar{y} = \tfrac{1}{2} \text{ of } \frac{\alpha_1^2 + \alpha_n^2 + 4(\alpha_2^2 + \alpha_4^2 + \alpha_6^2 + \&\text{c.}) + 2(\alpha_3^2 + \alpha_5^2 + \alpha_7^2 + \&\text{c.})}{\alpha_1 + \alpha_2 + 4(\alpha_2 + \alpha_4 + \alpha_6 + \&\text{c.}) + 2(\alpha_3 + \alpha_5 + \alpha_7 + \&\text{c.})};$$

whence the centre of gravity of the curve is completely determined.

Note 9.—We next proceed to show how the centre of gravity of the volume of a figure similar to fig. 4, page 144, may be found, its equation being

$$z = A + Bx + Cx^2 + B_1 y + C_1 y^2 + Dxy + Ex^2 y + Exy^2 + G_1 x^2 y^2.$$

By formulæ 2 if we integrate in regard to z,

$$\bar{x} = \frac{\int\int xz\,dxdy}{\int z\,dx\,dy} =$$

$$\frac{\int_0^{2h}\int_0^{2k} xdxdy\,(A + Bx + Cx^2 + B_1 y + C_1 y^2 + Dxy + Ex^2 y + Exy^2 + Gx^2 y^2)}{\int_0^{2h}\int_0^{2k} dxdy\,(A + Bx + Cx^2 + B_1 y + C_1 y^2 + Dxy + Ex^2 y + Exy^2 + Gx^2 y^2)}$$

$$= \frac{\frac{hk}{9}\{36Ah + 48Bh^2 + 72Ch^3 + 36B_1 hk + 48C_1 hk^2 + 48Dh^2k + 72Eh^3k + 64Fh^2k^2 + 96Gh^3k^2\}}{\frac{hk}{9}\{36A + 36Bh + 48Ch^2 + 36B_1 k + 48C_1 k^2 + 36Dhk + 48Eh^2k + 48Fhk^2 + 64Gh^2k^2\}}.$$

But $A = \alpha_1$, $B = \frac{4\alpha_2 - 3\alpha_1 - \alpha_3}{2h}$, $C = \frac{\alpha_1 - 2\alpha_2 + \alpha_3}{2h^2}$, &c. as was shown on page 140. Introducing these values, we find—

$$\bar{x} = h\,.\,\frac{2(2\alpha_2 + \alpha_3) + 8(2\beta_2 + \beta_3) + 2(2\gamma_2 + \gamma_3)}{\alpha_1 + 4\alpha_2 + \alpha_3 + 4(\beta_1 + 4\beta_2 + \beta_3) + \gamma_1 + 4\gamma_2 + \gamma_3}$$

$$\bar{y} = \frac{\int\int yz\,dxdy}{\int\int z\,dxdy} = \frac{\int_0^{2h}\int_0^{2k} dxdy\ y(A + Bx + Cx^2 + B_1 y + C_1 y^2 + Dxy + Ex^2 y + Exy^2 + Gx^2 y^2)}{\int_0^{2h}\int_0^{2k} dxdy\,(A + Bx + Cx^2 + B_1 y + C_1 y^2 + Dxy + Ex^2 y + Fxy^2 + Gx^2 y^2)}.$$

$$= \frac{\frac{hk}{9}\{36Ak + 36Bhk + 48Ch^2k + 48B_1 k^2 + 72C_1 k^3 + 48Dhk^2 + 64Eh^2k^2 + 72Fhk^3 + 96Gh^2k\}}{\frac{hk}{9}\{36A + 36Bh + 48Ch^2 + 36B_1 k + 48C_1 k^2 + 36Dhk + 48Eh^2k + 48Fhk^2 + 64Gh^2k\}};$$

which, after introducing the values of the constant, and reducing, becomes

$$\bar{y} = k\,.\left\{\frac{2(2\beta_1 + \gamma_1) + 8(2\beta_2 + \gamma_2) + 2(2\beta_3 + \gamma_3)}{\alpha_1 + 4\alpha_2 + \alpha_3 + 4(\beta_1 + 4\beta_2 + \beta_3) + \gamma_1 + 4\gamma_2 + \gamma_3}\right\}.$$

Also,

$$\bar{z} = \frac{\int\int z^2\,dxdy}{\int\int z\,dxdy}.$$

But, as before, we avoid the labour of integrations, &c., if we consider the expression $\int\int z^2\,dxdy$ as the volume of a figure, *the squares of the areas* of which may be introduced into "Simpson's Rule."

We should obtain similar expressions for the centres of gravity of the volumes of the other solids, and by introducing the results into the formulæ—

$$\bar{x} = \frac{V_1 \bar{x}_1 + V_2 \bar{x}_2 + V_3 \bar{x}_3 + \&\text{c.}}{V_1 + V_2 + V_3 + \&\text{c.}}$$

$$\bar{y} = \frac{V_1 \bar{y}_1 + V_2 \bar{y}_2 + V_3 \bar{y}_3 + \&\text{c.}}{V_1 + V_2 + V_3 + \&\text{c.}}$$

we obtain the rule, in common use among naval architects, namely:—

If A_1, A_2, A_3, &c. represent the areas of half the horizontal sections, or the sections shown by the half-breadth plan, and h the common interval between those sections, we know that the centres of gravity of the areas in question lie in the planes of these areas at distances 0, h, $2h$, $3h$, &c., respectively, from the origin.

$$\text{(III.)}\ \therefore \bar{x} = \frac{A_1 \times 0 + (n-1)hA_n + 4h(A_2 + 3A_4 + 5A_6 + 6A_8 + \&\text{c.}) + 2h(2A_3 + 4A_5 + 6A_7 + \&\text{c.})}{A_1 + A_n + 4(A_2 + A_4 + A_6 + \&\text{c.}) + 2(A_3 + A_5 + A_7 + \&\text{c.})};$$

$$\text{or } \bar{x} = h\,.\left\{\frac{(n-1)A_n + 4(A_2 + 3A_4 + 5A_6 + \&\text{c.}) + 2(2A_3 + 4A_5 + \&\text{c.})}{A_1 + A_n + 4(A_2 + A_4 + A_6 + \&\text{c.}) + 2(A_3 + A_5 + A_7 + \&\text{c.})}\right\}.$$

In like manner, if A_1', A_2', A_3', &c. represent the half areas of the vertical section, and k the common interval between them.

$$\text{(IV.) Then } \bar{y} = k\left\{\frac{(n-1)A_n' + 4(A_2' + 3A_4' + 5A_6' + \&\text{c.}) + 2(2A_3' + 4A_5' + \&\text{c.})}{A_1' + A_n' + 4(A_2' + A_4' + A_6' + \&\text{c.}) + 2(A_3' + A_5' + \&\text{c.})}\right\}.$$

Hence the centre of gravity of the displacement is determined; for we know that it will lie somewhere in the plane which cuts the vessel into two equal parts, and the value of $\bar{x}$ gives its distance below the load-water plane, $\bar{y}$ gives its distance from the origin,

Calculations incidental to designing a Ship.

which may be taken for convenience at the point of intersection of the load-water plane, the plane just mentioned, and the first vertical plane next the bow, or stern (as the calculator pleases). We will suppose the former, and that the centres of gravity of the small portions, fore and aft, and below the last horizóntal plane, are not taken into account. Let V_f, V_a, V_k, be their volumes, $\bar{x}_f$, $\bar{x}_a$, $\bar{x}_k$, $\bar{y}_f$, $\bar{y}_a$, $\bar{y}_k$, the distances of their centres of gravity from the origin. Therefore, for the whole ship, V representing the volume between the first and last vertical sections,

$$\bar{X} = \frac{V\bar{x} + V_k \bar{x}_k + V_a \bar{x}_a - V_f \bar{x}_f}{V + V_k + V_a + V_f}$$

$$\bar{Y} = \frac{V\bar{y} + V_k \bar{y}_k + V_a \bar{y}_a + V_f \bar{y}_f}{V + V_k + V_a + V_f}.$$

Observe that $V_f \bar{x}_f$ has a negative sign because it is in the opposite side of the origin to the other quantities, that is, x_f is negative.

Note 10.—The mathematical reader will at once perceive that these are not the only rules which might be obtained to calculate the centre of gravity of a vessel. As has been remarked before, the Calculus of Finite Difference again comes to our aid; and, by neglecting small orders of differences, we may obtain any number of rules we please. As an instance, let us take the case given by Mr Weddle for a curve passing through seven points, and suppose sixth differences constant. We have for $\bar{x}$, using the same notation as in Note 3,

$\bar{x} = \int xy\,dx$ taken between proper limits; and $y = \alpha + z\,\Delta\alpha + z(z-1)\frac{\Delta^2\alpha}{1\cdot 2} + \&c.$; where $z = \frac{x}{h}$. Multiplying this by $zdz = \frac{xdx}{h^2}$, we have $\bar{x}$ or $\frac{1}{h^2}\int xy\,dx = \int \left\{ \alpha\,zdz + (z^2dz)\,\Delta\alpha + (z-1)\,dz\,.\,\frac{\Delta^2\alpha}{1\cdot 2} + \&c. \right\} = \frac{\alpha z^2}{2} + \frac{z^3}{3}\,\Delta\alpha + \left(\frac{z^4}{4} - \frac{z^3}{3}\right)\frac{\Delta^2\alpha}{1\cdot 2} + \left(\frac{z^5}{5} - \frac{3z^4}{4} + \frac{2z^3}{3}\right)\frac{\Delta^3\alpha}{2\cdot 3} + \left(\frac{z^6}{6} - \frac{6z^5}{5} + \frac{11z^4}{4} - \frac{6z^3}{3}\right)\frac{\Delta^4\alpha}{2\cdot 3\cdot 4} + \left(\frac{z^7}{7} - \frac{10z^6}{6} + \frac{35z^5}{5} - \frac{50z^4}{4} + \frac{24z^3}{3}\right)\frac{\Delta^5\alpha}{2\cdot 3\cdot 4\cdot 5} + \left(\frac{z^8}{8} - \frac{15z^7}{7} + \frac{85z^6}{6} - \frac{225z^5}{5} + \frac{274z^4}{4} - \frac{120z^3}{3}\right) \times \frac{\Delta^6\alpha}{1\cdot 2\cdot 3\cdot 4\cdot 5\cdot 6} + \&c.\ \&c.$

Taking this integral from $z = 0$ to $z = 6$, or $x = 0$ to $x = 6h$, and multiplying by h^2, we find, after considerable reductions,

$$\bar{x} = h^2\left\{18\alpha + 72\,\Delta\alpha + 126\,\Delta^2\alpha + \frac{606}{5}\,\Delta^3\alpha + \frac{657}{10}\,\Delta^4\alpha + \frac{639}{35}\,\Delta^5\alpha + \frac{123}{70}\,\Delta^6\alpha\right\}.$$

We might obtain a tenth rule by neglecting small quantities; but we shall simply write down the total result, leaving the reader to obtain any other rules he may think proper.

$$\alpha = \alpha_1$$
$$\Delta\alpha = \alpha_2 - \alpha_1$$
$$\Delta^2\alpha = \alpha_3 - 2\alpha_2 + \alpha_1$$
&c. &c.

Introducing these values, and reducing

$$\bar{x} = \frac{h^2}{70}\left\{36\,\alpha_2 + 9\alpha_3 + 136\,\alpha_4 + 18\,\alpha_5 + 180\,\alpha_6 + 61\alpha_7)\right\}$$

$$= \frac{9h^2}{70}\left\{\frac{28\,\alpha_4 + 5\alpha_7}{9} + 4\,(\alpha_2 + 3\alpha_4 + 5\alpha_6) + (\alpha_3 + 2\alpha_5 + 4\alpha_9)\right\};$$

which will give a result much more accurate than that obtained by "Simpson's Rule." The result for $\bar{y}$ may be obtained by "Simpson's Rule," or by squaring the value of y, given above, and neglecting the squares and products of higher order of differences.

Property of Guldinus.

Note 11.—The reader will have no difficulty in obtaining for any plane surface[1]

$$\bar{y} = \frac{\int\int y\,dx\,dy}{\int y\,dx};$$

or $\bar{y} \times A = \frac{1}{2}\int (Y_1^2 - Y_0^2)\,dx$; if A represent the area of the surface, and Y_1 Y_0 denote the limits of y. Multiply both sides by 2π.

$$\therefore\ A \times 2\pi\,\bar{y} = \pi\int Y_1^2\,dx - \pi\int Y_0^2\,dx.$$

The left hand side is the area of the surface multiplied by the circumference described by its centre of gravity, and the right hand side denotes the difference of the volumes of revolution described by the plane surfaces comprised between the axis of x, the extreme ordinates, and the two curves which terminate the generating surface.[2]

Examples.

(1.) Find the centre of gravity of an area, similar to fig. (1.) page 140, the equidistant ordinates measuring 2·5, 3, 3·5, 4, 5, 6, 5·5, 5, 4, 3, 2, 1·5 and 1 feet, respectively, the common interval being 2 feet.

Exercises for practice.

2. Find the centre of gravity of a figure similar to the above, when the ordinates are taken 3 feet apart, and measure 1·25, 2·35, 4·56, 7·87, 8·97, 9·65, 10·54, 9·97, 8·65, 7·54, 6·34, 7·43, 5·42, 4·53, 4·23 feet, respectively.

Distance along the axis from A_1 = 20·82.
Distance above the axis at the above point = 3·945.

(3.) Find the same, as in the last example, when the equidistant ordinates measure 20, 20·5, 21, 22, 22·5, 23, 24·5, 25, 26; 25, 24, 23; 23, 22·5, 21, 20; 19, 18, and 17 feet, respectively, and are taken at 6 feet apart.

Distance along the axis $A_1\,A_n$ from A_1 = 52·82.
Perpendicular distance above ditto at the above point = 11·18.

(4.) Find the same, as in the former examples, when the ordinates are 0, 2, 3, 3·5, 4·5, 5, 6, 7·5, 8, 8·5, 9, 8, 7, 6, 5·5, 4·5, 4, 3·5, 3, 2·5, and 2 feet, and their distance apart is 2 feet.

Distance along $A_1\,A_n$ from A_1 = 20 feet nearly.
Distance above $A_1\,A_n$ at the above point = 3·0506.

(5.) Find the same when the equidistant ordinates measure 17, 18, 18·5, 19, 19·5, 20, 20·5, 21, 22, 23, 22, 21·5, 20, 19, and 18 feet, their distance apart being 4 feet apart.

Distance along $A_1\,A_n$ from A_1 = 28·605.
Distance above $A_1\,A_n$ at the above point = 10·134.

[1] The calculator will always have a check on his work by observing the length of the axis $A_1\ A_n$, and observing also whether or not the ordinates near the beginning differ widely from those at the end. If the ordinates do not differ widely in this sense, the centre of gravity will be determined by a line perpendicular to the axis *near* its middle point. If the ordinates are greater near the beginning than at the end, the centre of gravity determined along $A_1\ A_n$ will be nearer the *first* ordinate than the *last*, and *vice versâ*.

Calculations incidental to designing a Ship.

Therefore, distance of centre of gravity of main body *below* the plane of flotation $= \frac{70098\cdot\dot{6}}{\text{volume}} = \frac{70098\cdot\dot{6}}{7643\cdot23} = 9\cdot17$ feet.

$\therefore$ distance of centre of gravity from first vertical section $= \frac{531001\cdot74}{7643\cdot23}$
$= 69\cdot47$ feet.

We shall *suppose* the *first* vertical section 49·75 to be that nearest the *bow*, and

234·25 cubic feet, to be the volume of the portion below the last horizontal section, or the portion just above the keel.

22·5 feet, the distance of its centre of gravity below the plane of flotation.
70· „ from the first vertical plane.

324·75 cubic feet, the volume of the portion *before* the first vertical plane, or between this plane and the bow.

10 and 7 feet, the respective distances of the centre of gravity from the same planes as above.

576·00 cubic feet, the volume of the portion *aft* of the last vertical plane, or lying between this plane and the stern.

8 and 160 feet, the respective distances of the centre of gravity from the planes already mentioned.

Then, if d_f, d_v, be the distances of the centre of gravity of the total displacement from the planes of flotation and first vertical, we have

$$d_f = \frac{7643\cdot23 \times 9\cdot17 + 234\cdot25 \times 22\cdot5 + 324\cdot75 \times 10 + 576 \times 8}{7643\cdot23 + 234\cdot25 + 324\cdot75 + 576}$$
$$= 9\cdot48 \text{ feet below the plane of flotation.}$$

$$d_v = \frac{7643\cdot23 \times 69\cdot47 + 234\cdot25 \times 70 + 576 \times 160 - 324\cdot75 \times 7}{7643\cdot23 + 234\cdot25 + 576 + 324\cdot75}$$
$$= 71\cdot8 \text{ nearly.}$$

Stability of Floating Bodies.

The reader will perceive that all the quantities are *added* in obtaining the former result, and that the last one is *subtracted* in the latter case. The reason for this is, that, in the latter case, the portion forward lies on the *opposite* side of the first vertical plane to all the rest, or is measured, what we have called, *backwards*. Now, if we had considered the first vertical section, 49·75, as being taken at the stern, then 324·75 × 7 would have been *added*, and 576 × 160 *subtracted*, in consequence of the portion aft lying, in this case, on the opposite side of the first vertical plane to the other portions. In the first result, all the portions lie *below* the plane of flotation. We also perceive that the centre of gravity lies between the sixth and seventh vertical sections, inasmuch as their common distance is 10·56, and 10·56 × 6 = 63·36; also, 10·56 × 7 = 73·92; therefore 71·8 − 63·36 = 8·44 feet abaft the sixth section.

STABILITY OF FLOATING BODIES.

Theory: General principles.

ART. 6.—Various definitions have been given of the *stability* of floating bodies. The reader will probably comprehend the term from the explanation and definitions which follow.

Euler, in his *Theory of the Construction of Vessels*, &c., as translated by Colonel Watson, observes, that " As soon as a vessel becomes ever so little inclined, or displaced from its state of equilibrium, three consequences may happen:—1*st*, Either the vessel remains in the inclined state; or, 2*dly*, It re-establishes itself in its preceding situation, when its equilibrium will be permanent, or rather, it will be endowed with a stability which may be great or little according to circumstances; or, 3*dly*, The vessel after this inclination will be completely overturned. This equilibrium is called unstable, or ready to fall. We can see, evidently, that neither this last case nor the first can have place in vessels; and, with respect to the second case, a sufficient stability is absolutely necessary."[1]

The last remarks here made are not altogether true when a vessel is inclined through considerable angles by impulsive forces. We shall therefore proceed to investigate the different kinds of stability.

Statical stability.

DEF. (I.)—STATICAL STABILITY *is defined to be the moment of* FORCE *(or effort), by which a floating body endeavours to regain its upright or vertical position, after having been deflected from that position.*

DEF. (II.)—DYNAMICAL STABILITY *is defined to be the amount of work*[2] *done on any body, in order to deflect it through any angle from its upright position.*

As has already been stated, it is shown in books on Hydrostatics, that when a body floats *in equilibrium*, the following conditions must be fulfilled:—

1*st*, $g\varrho V_d = gM$, or simply $\varrho V_d = M$,

where M represents the mass of the floating body, V_d the volume of water displaced, ϱ the density of a cubic unit (say a cubic foot) of water, and g the accelerating force of gravity.

2*nd*, The centres of gravity of the body, and of the water which it displaces, must lie in the same vertical line—that is, in a line at right angles to the plane of flotation.

From the first condition, namely $V_d = \frac{M}{\varrho}$, it is at once manifest, that in many bodies, such as some of the solids of revolution, this will furnish us with an infinite number of positions of equilibrium, for all of which the second condition will be fulfilled.

When a body is inclined through any angle from its upright position, the plane of flotation will differ in position from the plane of flotation in the former case; and for every plane of flotation the centres of gravity of the vessel and its displacement will,

[1] *Vide* chap. iv., sect. 22, of the work here mentioned.

[2] By the amount of work, here alluded to, is meant the weight of the body, in pounds avoirdupois, multiplied by the vertical height, in feet, of the sum or difference of displacements of the centres of gravity of the body and of the water which it displaces.

Stability of Floating Bodies.

in general, have different positions. If we suppose the vessel to *roll* and *pitch*[1] uniformly through any finite angles, the centre of gravity of displacement G_d, or centre of buoyancy, as this point is sometimes called, will describe a portion of a surface in the interior of the vessel.

It will readily be comprehended by the reader, that a vessel may possess a great amount of both kinds of *stability* specified in the definitions up to a certain point, that is, through a given angle from its upright position, and then instantaneously become unstable. Sufficient attention has not been paid to this fact, inasmuch as writers on stability, as applied to ships, generally neglect to discuss the case of unstable equilibrium. It is a well-known fact, that ships have been capsized through unforeseen impulsive forces, as in the case of the Royal George.[2] When the vessel has been inclined through any angle, it has been always customary to assume that the volume of the portion which is *emerged* is equal to that which is *immersed*. This is not accurately true, on account of the inertia of the vessel and the water, as well as on account of the effect of the wind in the sails, which may tend to increase the total displacement.

ART. 7. THEOREM I.—*The line joining the centres of gravity of the displacement of the body in any two positions is parallel to the line joining the centres of gravity of the immersed and emerged portions due to these positions.*

For, let FKL′ represent a transverse section of the body, made by the plane of the paper, and G_d, G'_d the projections of the centre of gravity of displacement in the two positions, g_e, g_i the projections of the centres of gravity of the *emerged* and *immersed* volumes due to the two positions.

Then the immersed portion of the body in the two positions will have the common part

$$V_d - v$$

(the section of which is shown by F′PLK), where v represents the volume of the part emerged or immersed.

Let O′ be the projection of the centre of gravity of the volume $V_d - v$ on the plane of the paper, then by the principles which have been already enunciated (Art. 4, p. 147, &c.), the centre of gravity G_d is determined from

$$G_d\, g_e \times v = G_d\, O' \times (V_d - v) \quad . \quad . \quad . \quad . \quad . \quad (1.)$$

and the centre of gravity G'_d, in like manner from

$$g_i\, G'_d \times v = G'_d\, O' \times (V_d - v) \quad . \quad . \quad . \quad . \quad (2.)$$

By (1.) and (2.) $g_e\, G_d \times G'_d\, O' = g_i\, G'_d \times G_d\, O'$;

or, $g_e G_d : G_d O' :: g_i G'_d : G'_d O'$;

hence $G_d\, G'_d$ is parallel to $g_e\, g_i$. (*Euclid*, vi. 2.)

Next, if we consider the volumes immersed and emerged to be infinitely small, or, in other words, the two planes of flotation, of which FL, F′L′, are the projections, to be indefinitely near, the centres of gravity of these two volumes may be considered as situated in the plane of flotation (FL). In this case $G_d\, G'_d$ becomes parallel to FL, that is, $G_d\, G'_d$ becomes a *tangent* at G_d, to the *curve* traced out by the latter point in the plane of the paper. This is rigorously true at the limit, no matter in which direction we suppose the body to revolve (through an infinitely small angle); it follows, therefore, that all the tangents drawn through G_d are parallel to the plane of flotation; hence

THEOREM II.—*The* TANGENT PLANE,[3] *drawn through the centre of gravity of displacement in position to the surface traced out by this point during the rolling and pitching of the vessel, is parallel to the plane of flotation corresponding to that position.*

ART. 8.—If G (fig. 7) denote the centre of gravity of the floating body, and G_d that of the water displaced, then in positions of equilibrium G_d G is a *normal*[4] to the surface described by the latter points. For, by the second condition of equilibrium, given in Art. 14, G_d G, is necessarily perpendicular to the plane of flotation, and is, therefore, perpendicular to the tangent-plane at the point G_d, since the latter plane is parallel to the former. Let us suppose the surface traced out by G_d to be actually described, then if from G, the centre of gravity of the body, we draw all the normals which it is possible to do from this point to the surface, we shall determine as many positions of G_d as there are

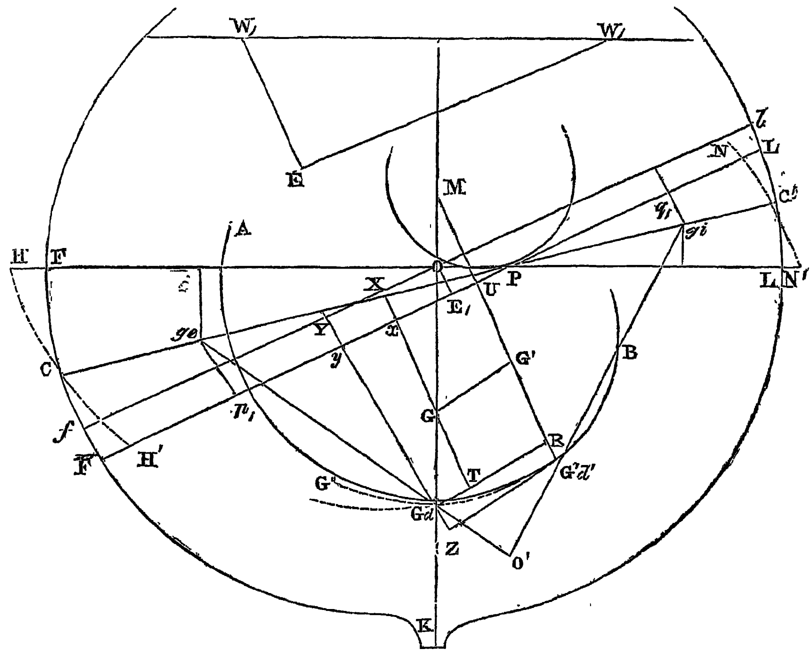

Fig. 7.

normals, and consequently as many planes of flotation, for all of which there will be equilibrium of one kind or the other—that is, *stable* or *unstable*.

A rolling motion will be sufficient to establish the following principles:—

Let us suppose the plane of the paper to be that transverse vertical section of the vessel which contains the centres of gravity of the vessel and its displacement when floating *at rest*. Next let the body be made to roll through any angle, and the point G_d will describe a curve in the same plane, which is represented by AG_dB.

Let G_d, G'_d (fig. 7) be two consecutive positions of the centre of gravity of displacement (that is, two positions indefinitely near to each other); draw normals through these two points to the curve AG_dB, and let them intersect in M, the latter point in geometry and analysis receives the name of the *centre of curvature*; but in regard to the floating body it was named by Bouguer the *metacentre*, and the circle described through G_d with radius MG_d is called the *circle of curvature*, or sometimes the *osculating circle*.

The curve described by the centre of gravity of displacement (centre of buoyancy) has been named the *metacentric curve*. Mr Read, late master-shipwright of H.M. Dockyard, Sheerness, pro-

[1] By a *rolling* motion is understood a motion about a longitudinal axis, or from stem to stern. By a *pitching* motion is to be understood the motion of the vessel about an axis at right angles to the former axis, or about an axis which lies in a transverse vertical section. During a *rolling* motion only, the centre of gravity of the vessel will remain in the same transverse section; and during a *pitching* motion only, the centre of gravity will remain in a vertical section at right angles to the former. When the motion is due to rolling and pitching combined, the vessel will revolve about an *instantaneous axis*, which may be determined.

[2] And in all probability many other vessels.

[3] By a *tangent-plane* is here meant a plane which *touches* the surface described by G_d at a given point, and which, if produced, does not intersect this surface. For the general definition of a tangent-plane and its properties, see Hymers's and Gregory and Walton's *Geometry of Three Dimensions.*

[4] By a *normal* to a surface at a given point is meant the line drawn at right angles to the tangent-plane at that point.

Stability of Floating Bodies.

posed to call it the *metacentric involute*, and the curve described by M the *metacentric evolute*,[1] which terms are strictly in accordance with mathematical theory.

It will be seen hereafter that the position of the metacentre is of the greatest importance in the determination of the stability and times of oscillation of vessels. Its height above the centre of gravity of displacement may be determined as follows—

ART. 9.—The notation and figure remaining the same as in the previous article; the ordinates measured on *the half-breadth plan* at the load-water line being employed.

RULE XIV.—*Cube the ordinates measured on the half-breadth plan, introduce these* CUBES *as ordinates in Rule I., p.* 140, *and proceed as therein stated; divide the result thus obtained by the volume of water displaced, and* TWO-THIRDS *of the quotient gives the distance of the metacentre from the centre of gravity of displacement.*

Let the vessel be slightly inclined from its upright position, we may consider the areas FPF′ and LPL′ to be two equal sectors of the same circle;[2] then $g_e\,g_i$, the line joining their centres of gravity, will bisect this angle. Draw $g_e\,p_1$, $g_i q_1$ perpendicular to FF′, and G_dR perpendicular to MG'_d.

Let $r = FP = F'P = LP = L'P$, and it is well known that the centres of gravity are determined by

$$Pg_e = Pg_i = \frac{2\,r\,.\,\text{chord FF}'}{3\text{ arc FF}'} = \frac{2\,r\,.\,\text{chord LL}'}{3\text{ arc LL}'}$$

$$= \frac{4\,r\sin\frac{\phi}{2}}{3\,\phi},\ \phi\text{ being} = \angle\,FPF'$$

But area of sector FPF′ or PLL′ $= \frac{r^2\phi}{2}$. And

$$P\,p_1 = P\,q_1 = P\,g_e\,.\cos\frac{\phi}{2} = P\,g_i\,.\cos\frac{\phi}{2} = \frac{4\,r\sin\frac{\phi}{2}\cos\frac{\phi}{2}}{3\,\phi} = \frac{2\,r\sin\phi}{3\,\phi}.^{3}$$

Also moment of sector FPF′, or sector LPL′, $=$ area FPF′ $\times P\,p_1$

$$= \text{area LPL}' \times P\,q_1 = \frac{r^2\phi}{2} \times \frac{2\,r\sin\phi}{3\,\phi}.$$

$$= \frac{r^3\sin\phi}{3}. \quad \ldots\ldots\ldots \quad \text{(I.)}$$

Now, since the solids emerged and immersed are supposed to be equal, and that these solids may be conceived to be collected at their respective centres of gravity, it is clear that the centre of gravity of the volume of water emerged has been moved from p_1 to q_1 in the direction F′L′, while the total volume of water displaced by the vessel has been transferred from G_d to R in a parallel direction. Hence taking moments, we have, by elementary mechanical principles,

$$G_dR \times \varrho \times V_d = p_1 q_1 \times \varrho \times v. \quad \ldots\ldots \quad \text{(II.)}$$

Or, $G_dR\,.\,V_d = p_1 q_1\,.\,v$.

But the angle FPF′ $=$ angle $G_dMG'_d$ between two consecutive normals

$$\therefore\ MG_d\sin\phi = G_dR$$

$$\text{From (II.) } MG_d = \frac{p_1 q_1\,.\,v}{V_d\sin\phi}. \quad \ldots\ldots \quad \text{(III.)}$$

Now, if we imagine a plane drawn parallel to the plane of the paper, or to the section shown in the figure, and at the infinitesimal distance Δx, the moments of the volumes of the solids emerged and immersed will be represented by

$$\frac{\sin\phi}{3}\,\Sigma\,r^3\,\Delta\,x,\text{ from (I.), or }\frac{\sin\phi}{3}\int r^3 dx;$$

by employing the notation of the Integral Calculus, observing that the integral here given must be taken from stem to stern.

$$\therefore\ MG_d = \frac{2\sin\phi}{3}\,.\,\frac{1}{V_d\sin\phi}\int r^3\,dx. \quad \ldots \quad \text{from (III.)}$$

$$= \frac{2}{3\,V_d}\int r^3\,dx. \quad \ldots\ldots\ldots\ldots \quad \text{(IV.)}$$

The integral, $\int r^3\,dx$ is sometimes named the *moment of inertia* of the load-water section FL, about a horizontal axis through the centre of gravity.

It ought to be observed that, though we have here obtained the position of the metacentre of the vessel when in a vertical position, this point may in like manner be obtained, by employing the same rule, when the vessel is inclined through any angle, providing we substitute the ordinates of the *inclined load-water section* for those of the load-water section of the vessel when in an upright position.

ART. 10.—Having obtained the position of the metacentre, we are now in a position to determine the *nature* of the equilibrium when a vessel is in any position; for, if we call the lengths of the lines drawn from G, perpendicular to the curve described by G_d, NORMALS, then

THEOREM III.—*Positions of* STABLE *equilibrium correspond to* MINIMUM *normals, and positions of* UNSTABLE *equilibrium correspond to* MAXIMUM *normals: also these normals will have alternately maximum and minimum values.*[4]

Various demonstrations of this theorem have been given in books on Hydrostatics, and the reader will find the subject discussed in the *Mechanic's Magazine*, a periodical which contains many valuable papers on shipbuilding. The following exposition of the principle may be found sufficient for the mathematical reader.

If (fig. 7) M be the *centre of curvature* corresponding to G_d, and situated at first above G, the osculating circle at G'_d will lie both within and without the curve AG_dB in the immediate neighbourhood of G_d, and the circle described from G as a centre, with radius GG_d, will lie entirely within the curve in the vicinity of G_d, and the normal GG_d will be a *minimum* among all those drawn from G to the points of the curve in the neighbourhood of G_d; that is, GG_d will be less than GG'_d and GG''_d. If M lie below G, we learn by the same reasoning that GG_d is greater than GG'_d and GG''_d, since the circle described from G with radius GG_d lies entirely without the curve AG_dB; that is, the contact is of the third order.[5]

These normals are alternately maxima and minima, since between two maximum values there is a minimum, and a maximum between two minima. There are as many maximum as minimum values; hence the number of positions of equilibrium, neglecting the *kind*, is *even*. Moreover,

THEOREM IV.—*When the metacentre lies* ABOVE *the centre of gravity of the vessel, the equilibrium is* STABLE.

For, if we incline the vessel in such a manner that G_d shall be at G'_d, indefinitely near to G_d, the normal at G'_d will pass through M (since the latter point is the intersection of two consecutive normals); then the weight of the water displaced applied at G'_d will be parallel to MG'_d, and will act upwards, whilst the weight of the body at G′ will act downwards in the direction parallel to MG'_d, and it is evident that the effect of these two forces will be to bring the points M and G'_d into their original position.

THEOREM V.—*When the metacentre lies* BELOW *the centre of gravity of the vessel, the equilibrium is* UNSTABLE.

For, inclining the vessel as before, through an indefinitely small angle, the effect of the two forces just mentioned will be to bring G′ and M into a vertical position; and since G is above M, the vessel will be capsized.

THEOREM VI.—*When the metacentre coincides with the centre of gravity, the equilibrium is said to be indifferent or neutral; that is, the vessel will rest in the position in which it is then placed.*

ART. 11.—Having obtained the *kind* of stability, we may

[1] The *metacentric curve* is that made by any plane (a transverse vertical one in the present case) with the metacentric surface.

[2] It is not necessary to consider the sectors as equal, providing we bisect the angle FPF′; and with centre P and radii PC, PC′, we describe arcs of circles intersecting the two planes of flotation (the projections of which are FL and F′L′), the same result as is obtained below may be shown to hold true.

[3] Because $2\sin\frac{\phi}{2}\cos\frac{\phi}{2} = \sin\phi$.

[4] *Maximum* and *minimum* values mean *greatest* and *least* values.

[5] See Hall's *Calculuses*, p. 200.

at once obtain the analytical condition for the NATURAL STABILITY of a body after having proved the following:—

THEOREM VII.—*The centre of gravity of a plane of flotation lies on the line of its intersection, with a plane of flotation indefinitely near to the former plane.*

Let PQ represent the intersection of the two planes here mentioned, g, g', the centres of gravity of the areas EPQ and LPQ, the areas being denoted by A and A′. Now, the centre of gravity of FPLQ is obtained by dividing $g\,g'$ into two parts reciprocally proportional to those areas. Let, then, φ be the infinitely small angle between the two planes of flotation, l and l' the perpendicular distances of g, g', from PQ. As the wedge-like portions emerged and immersed are exceedingly small, we may apply the principle of Guldinus, given at page 147, viz.:—[1]

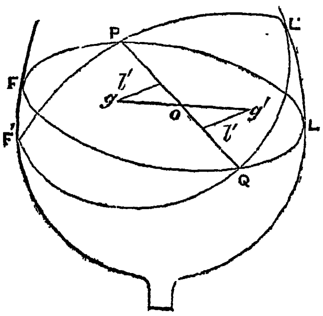

Fig. 8.

Volume F′FPQ $= Al\varphi$, and volume LL′PQ $= A'l'\varphi$; and since these volumes are equal

$$\therefore\ Al\varphi = Al'\varphi \text{ or } Al = A'l';$$

$$\text{that is, } l : l' :: A' : A \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

From the similar triangles ghO, $g'h'O$, we have,

$$l : l' :: gO : g'O \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

hence by (1) and (2),

$$gO : g'O :: A' : A;$$

that is, O is the centre of gravity of the plane of flotation.

It is clear that the point O will trace out a curve in the plane of the paper, provided the body be made to revolve through a finite angle in this direction, and F′L′ is a tangent at O to this curve. Moreover, the vessel might be made to revolve in any direction, and the point O would then trace out what is called the *surface of flotation*. From the manner in which we have obtained the result just given, we arrive at Euler's theorem, viz.,—

The point of contact of the plane of flotation with the surface of flotation is the centre of gravity of that plane.

Moreover, if we conceive (ΔA_1) to represent an elemental portion of the plane FPQF, and r_1 the distance of this element from PQ, then $\varphi\,(\Delta A_1)\,r_1$ will represent the corresponding volume of the portion FPQF′, assuming it to be a solid of revolution, and the total volume is got from

$$v = \varphi\,\{(\Delta A_1)\,r_1 + (\Delta A_2)\,r_2 + (\Delta A_3)\,r_3 + \&c.\} = \varphi\Sigma\,(\Delta A)\,r.$$

We know from the formula for determining the centre of gravity of bodies (p. 146), that

$$gO = \frac{\varphi\{(\Delta A_1)r_1^2 + (\Delta A_2)r_2^2 + (\Delta A_3)\,r_3^2 + \&c.\}}{\varphi\{(\Delta A_1)r_1 + (\Delta A_2)\,r_2 + (\Delta A_3)\,r_3 + \&c.\ \ \}}$$

$$= \frac{\varphi\Sigma(\Delta A)\,r^2}{\varphi\Sigma(\Delta A)\,r} = \frac{\varphi\int dA\,.\,r^2}{\varphi\int dA\,.\,r}.$$

By employing the notation of the Integral Calculus, and bearing in mind that these integrals are to be taken between proper limits:—

Now, $\int dA\,.\,r^2$ is called the *moment of inertia* of the plane PQF in regard to the axis PQ, the density being unity.

$\therefore gO = \dfrac{\varphi k_1}{v}$, . k_1 representing this moment of inertia; also,

$g'O = \dfrac{\varphi k_2}{v}$, where k_2 represents the moment of inertia of the plane LPQ, in regard to the same axis.

But $gg' = gO + g'O = \dfrac{\varphi\,(k_1 + k_2)}{v} = \dfrac{\varphi\,k}{v}$, k being the moment of inertia of the plane FPLQ in regard to PQ. Returning again to fig. 7, where g_e, g_i, represent the centres of gravity of the indefinitely small volumes emerged and immersed, we have shown that $g_e\,g_i$ is parallel to $G_d\,G'_d$.

$$\therefore\ \frac{G_d\,G'_d}{g_e\,g_i} = \frac{V_d}{v} = \frac{\varphi k}{V_d};$$

and φ being the angle between two consecutive normals, then $MG_d = \dfrac{G_dG'_d}{\sin\varphi} = \dfrac{G_dG'_d}{\varphi}$, since φ is exceedingly small, and the sine may be taken equal to the arc, and $g_e\,g_i$ is the same as the value of $g\,g'$ (given above) at the limit; hence

$$MG_d = \frac{k}{V_d} = \frac{\varrho\,k}{W} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (I.)$$

We have seen that the condition of *stable* equilibrium is $MG_d > GG_d$; so that if h denote the distance GG_d, the condition is

$$\frac{k}{V_d} > h, \text{ or } \frac{\varrho k}{W} > h \quad . \quad . \quad . \quad . \quad \quad . \quad . \quad . \quad . \quad (II.)$$

THEOREM VIII.—*The moment of inertia of the plane of flotation must be greater than the product of the volume of water displaced, and the distance between the centres of gravity of the body and its displacement.*

The value of k may be found from Equation IV., Art. 9.

$$\text{From (I.) } G_dM = GG_d + GM = \frac{\varrho k}{W}$$

$$\therefore GM = \frac{\varrho k}{W} - GG_d \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (III.)$$

ART. 12.—*To determine the line of intersection of the plane of flotation of the vessel, when in a vertical position with the plane of flotation, when the vessel has been inclined through any angle;* or to determine the point P (fig. 7) of the intersection of FL and F′L′.

Through O (fig. 7), the middle point of FL, draw $f\,l$, making the angle $FOf = LOl =$ given angle φ. Let the volumes, of which FOf and LOl are sections, be represented by V_1 and V_2 respectively; also, let v_1 and v_2 represent the volumes of which $EPOf$ and $LPOl$ are sections, and $v =$ volume emerged or immersed; then

$$V_2 = v + v_2;$$

$$\text{and } V_1 = v - v_1$$

$$\therefore\ V_2 - V_1 = v_1 + v_2$$

$= $ area of plane $f\,l \times$ OE (nearly) where OE is drawn perpendicular to F′L′.

$$\text{But OE} = \text{OP} \sin\varphi$$

$$\therefore\ \text{OP} = \frac{V_2 - V_1}{\text{area plane } f\,l \sin\varphi} \quad . \quad . \quad . \quad . \quad . \quad (I.)$$

Various methods have been recommended for the calculation of the solids V_2 and V_1 as well as for the volume v, all three of which are obtained in the same way. The following plan will guide the reader to find v:—

1*st*. Join FF′ and LL′, and the areas of the triangles FPF′; or LPL′ $= \dfrac{\text{FP . F'P} \sin\varphi}{2}$; or $\dfrac{\text{LP . L'P} \sin\varphi}{2}$.

2*d*. The curves FCF′ and LCL′ may be considered as parabolas, and the areas lying between FF′ or LL′ and the curves are equal to $\dfrac{2\,\text{FF} . \times \text{perpendicular height of segment FCF}'}{3}$, and $\dfrac{2\,\text{LL}' \times \text{perpendicular height of segment LC'L}'}{3}$; or we may employ 3*d* instead of 2*d* to find the areas of the segments just mentioned.

3*d*. When φ is very large, ordinates may be measured at right angles to FF′ and LL′ (seven will always be sufficient), and at equal distances apart, and the area found by Rule (III.) Art. 1. (or by Rule I.)

4*th*. Having found the areas FPF′ and LPL′ made by each vertical section, introduce these as ordinates in Rule (I.), and proceed as therein stated.

Remark.—Several writers have proposed to draw the ordinates, mentioned in (3), parallel to the plane of flotation. There is, however, little labour saved by such a plan.

For a very large number of vessels, which are *full* below the load-water plane, the following method may be applied, and will, it is believed, be found almost as accurate as those just recommended. Bisect the angle FPF′ by the line CC′, and with radii PC, PC′, describe the arcs HCH′ and NCN′; then the sectors will, in general, be very nearly equal in area to the portions FPF′ and LPL′. If CP $= r$, and C′P $= s$, then the area of the sector HPH′ $= \dfrac{r_1^{\,2}\varphi}{2}$, and area NPN′ $= \dfrac{s_1^{\,2}\varphi}{2}$. Summing these areas (by Rule

[1] We here suppose that the volumes emerged and immersed are solids of revolution, that is, solids described by the revolution of the planes FPQ and LPQ round PQ. This assumption will be accurate enough when the angle φ is very small, as we have assumed it to be.

I.) from stem to stern, and writing r_1, r_2, r_3, &c., for the 1st, 2d, 3d, &c., radii, with similar expressions for s, &c., we have

$$\text{Volume emerged} = \frac{h\phi}{6}\left\{r_1^2 + r_n^2 + 4\,(r_2^2 + r_4^2 + \&c.) + 2\,(r_3^2 + r_5^2 + \&c.)\right\}$$

$$\text{Volume immersed} = \frac{h\phi}{6}\left\{s_1^2 + s_n^2 + 4\,(s_2^2 + s_4^2 + \&c.) + 2\,(s_3^2 + s_5^2 + \&c.)\right\}$$

Calling the lines CP, C′P, measured on each vertical section, ordinates, we have the following approximate rule to find the volumes of the solids emerged or immersed:—

RULE XV.—*To the sum of the squares of first and last ordinates add four times the sum of the squares of all the even ordinates, and twice the sum of the squares of all the odd ordinates; multiply this result by the common distance and by the angle through which the ship has rolled—divide by 6, and we obtain the volume required (nearly).*

ART. 13.—Returning to Art. 7, and referring to fig. 7,

Draw GT parallel to $M\overline{G}$ and GG′ parallel to G_dR.

Then, $G^dR \cdot \varrho \cdot V_d = p_1q_1 \cdot \varrho \cdot v$;

And $\quad GG' = G^dR - G_dT$

$$= \frac{P_1q_1 \cdot \varrho \cdot v}{\varrho V_d} - GG_d \sin\phi.$$

$\because \quad \varrho V_d \cdot GG' = p_1q_1 \cdot \varrho \cdot v - GG_d \cdot \varrho \cdot V_d \sin\phi$;

Or, $\quad W \cdot GG' = (p_1q_1 \cdot w - GG_d \cdot W \sin\phi) \quad . \quad . \quad . \quad (I.)$

w representing the weight of water emerged or immersed; Formula (I.) measures the *statical stability*, Def. (I.) of a vessel as given by Atwood in his paper published in the *Transactions of the Royal Society* for the year 1796.

ART. 14.—The rule most frequently used by naval architects to determine the centre of gravity of a vessel, when fully equipped for sea, is due to Chapman, and is as follows:—

Suppose any weight (or weights) W_1, either on the upper deck or elsewhere, is moved from its position at W_1 (fig. 7) to another position, as W'_1, and that by this change of position the ship has been inclined through the angle ϕ. From W'_1 (the centre of gravity of the weight or weights) draw W'_1E parallel to $F'L'_1$, and W_1E perpendicular to W'_1E; then $W'_1E = W_1W'_1 \cos\phi = c \cos\phi$; if $W_1W'_1 = c$.

So long as the disturbing weight W_1 remains in its new position W'_1, the vessel will remain in equilibrium, and therefore its centre of gravity must lie in the line G'_dM by the second condition of equilibrium. Hence it has been transferred a distance GG′ parallel to the plane of flotation F′L′, while W_1 has been moved through a distance W'_1E in a parallel direction. Taking moments, we have

$$W \cdot GG' = W_1,\ c \cos\phi.$$

From Equation I. of last article—

$$GG' = \frac{p_1\,q_1\,w - GG_d \cdot W_1 \sin\phi}{W}.$$

Writing this latter value of GG′ in the former equation, we get

$$GG_d = \frac{p_1q_1\,w_1 - cW_1 \cos\phi}{W \sin}$$

which determines the centre of gravity of the ship, when the centre of gravity of displacement has been determined.

Mr Abethell, master-shipwright of H.M. Dockyard, Portsmouth, proposed the following method, in the second volume of the *Papers on Naval Architecture*:—

"It is applicable whenever a ship is taken into dock with the under side of her keel deviating from parallelism with the upper surface of the blocks. This is almost always the case; and it also not unfrequently occurs that ships are docked 'all standing,' and with so large a portion of their armament and stores on board, that the correction necessary to be made to the result which would be obtained by the experiment and investigation about to be described, in order to make that result agree with the circumstances of any additional armament and equipment, would be comparatively easy. We will now quote from the article in question.

"'We will suppose, by the falling of the tide in the dock, the after-extremity of the keel to come first in contact with the blocks; then, as the tide continues to fall, the after-body is gradually forsaken by the water, and the fore-body further immersed, a constant equilibrium being maintained between the total weight of the ship and the pressure of the water against the immersed part of the body, until the ship is aground fore and aft. At any intermediate instant the ship may be considered as a lever of the second kind, of which the fulcrum is the transverse line or point of contact of the keel and after-block, and the power and weight, the weight of the immersed volume and that of the ship respectively, each acting in the vertical line passing through its centre of gravity. As we can, by mensuration and calculation from the draught of the ship, easily find its weight, that of the immersed volume, and the perpendicular distance of the line of pressure from the fulcrum: in the equation of the moments, the distance of the vertical line passing through the centre of gravity of the ship is the only unknown quantity, which is therefore readily determined. AN (fig. 9) represents the

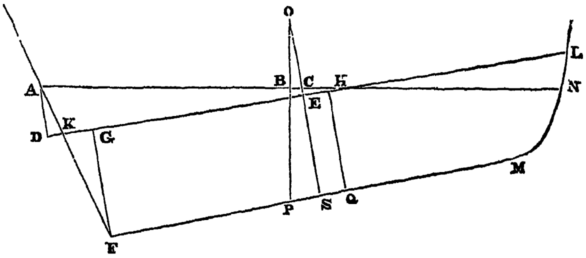

Fig. 9.

water-line corresponding to the floating position of the ship, and KL the observed water-line just previously to the fore-part of the keel touching the blocks. The line PBO, perpendicular to AN, passes through the centre of gravity of the displaced volume AFMN, and consequently through that of the ship. Draw QH through the centre of gravity of the volume KFML, perpendicular to KL, and FG through the fulcrum F, parallel to QH. Then, putting the total displacement AFMN $= V$, KFML $= v$, and GH $= b$; if the line SEO, parallel to QH, be drawn at the distance GE from G equal to $\frac{bv}{V}$, it will, as well as PBO, pass through the centre of gravity of the ship, which will be in O, the point of their intersection.

"'To obtain from these considerations a general expression for the perpendicular distance of the point O from the water-line AN, draw AD perpendicular to EG, and meeting it, when produced, in D; and having calculated the values of AB and GE, put AB $= a$, DE or DG+GE $= d$, and the angle of inclination between the water-lines AN and KL $= \Delta$; then BO $= \left(\frac{d}{\cos} \backsim a\right)\frac{1}{\tan\Delta}$; which must be set off upon the perpendicular PBO, above or below AN, according as $\frac{d}{\cos\Delta}$ is greater or less than a.'"

Dynamical Stability.

ART. 15.—Making the same construction as in fig. 7, and drawing GX and G_dY perpendicular to fl, meeting F′L′ in x and y respectively. Through G'_d draw G'_dZ parallel to F′L′, intersecting YG_d produced in Z.

Here it may easily be shown, that while W, the weight of the water displaced, has been moved through the distance G'_dR, the weight of that portion of the water *emerged* has been moved through a distance $g_e\,p_1 + g_i\,q_1$ in the same direction.[1] Taking moments,—

$$G'_dR \cdot W = w\,(g_e\,p_1 + g_i\,q_1) = wz;\ \text{if } z = g_e\ p_1 + g_i\,q_1$$

$$\text{But } GO - Gx = GO - (GX - Xx) = GO - GO\cos\phi + Xx$$
$$= GO \operatorname{vers}\phi + Xx \quad . \quad . \quad . \quad . \quad . \quad . \quad I.$$

which is the vertical distance through which the centre of gravity of the body has been raised.

$$\begin{aligned}\text{Also, } G'_dY - G_dO &= G^dY + G_dZ - G_dO\\ &= \overline{G}'_dR + G_dY - Xx - G_dO\\ &= G'_dR + G_dO\cos\phi - G_dO - Xx\\ &= G'_dR - (G_dO \operatorname{vers}\phi + Xx) \quad . \quad . \quad . \quad II.\end{aligned}$$

[1] See Moseley's paper, p. 619.

Stability of Floating Bodies.

which represents the height through which the centre of gravity of displacement has been raised.

Then there will be two cases: 1*st*, When the centres move in the *same* direction; 2*d*, When they move in *opposite* directions. In the first case, we shall have to subtract (I.) and (II.); in the second case add these results. Performing these operations, we have for the sum, or difference of the vertical displacements of the centre of gravity of the body, and that of the fluid which it displaces,

$$G'_d R - (G_d O \text{ vers } \varphi + Xx) + (GO \text{ vers } \varphi + Xx);$$

$$\text{Or, } G'_d R - GG_d \text{ vers } \varphi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{III.}$$

by taking the upper sign.

The dynamical stability is readily obtained by multiplying this result by the weight of the vessel; that is—

$$\text{Dynamical stability} = W\,(G'_d R + GG_d \text{ vers } \varphi) \quad . \quad . \quad . \quad \text{IV.}$$ [1]

Canon Moseley makes the following remarks at page 634 of his paper:—

"The force of the winds and waves, to the action of which a vessel is liable, may be supposed to vary as the surface she opposes to them; that is, to the area of her sails and the superficial dimensions of the hull. In vessels geometrically similar, these vary as the squares of any of their linear dimensions; their lengths, for instance. On the other hand, the weights of such vessels, supposed to be similarly loaded, varying as the cubes of their lengths; and the depths of their centres of gravity, and of the centres of gravity of their immersed parts varying as their lengths, their dynamical stabilities, with reference to a given inclination, vary as the fourth powers of their lengths. Since then, in reference to vessels thus geometrically similar, the disturbing forces, to the action of which they are subject, vary as the squares of their lengths, and their stabilities as the fourth powers, it follows that their actual steadiness in the water will vary as the *square* of their lengths, the greater vessel being more steady than the less in this proportion."

Time of Performing an Oscillation.

ART. 16.—There is much difficulty attending the investigation of the times of rolling and pitching of vessels through large angles, inasmuch as the *axis* about which the motion takes place is *instantaneous*. This axis can, however, be determined at any instant, providing the *direction* in which the ship is rolling or pitching be *given*.[2] All methods hitherto given are incomplete, yet all tend to show, that no matter what may be the amplitudes (the angles through which the vessel revolves, providing the position of the ballast, cargo, and other weights retain their original positions), the *time* of performing a complete oscillation, in smooth waters, is the same.

Writers on Hydrostatics, in investigating the time of an oscillation, have usually considered the plane of flotation as constant throughout the motion. The Rev. Canon Moseley, in his paper already quoted, endeavoured to obtain new results for the time of performing an oscillation, as well as for the dynamical stability of the vessel. Notwithstanding that several corrections have been made in the paper, as published in his second edition of *The Mechanical Principles of Engineering and Architecture*, the results are still open to the same objection, since they are made to depend upon the *moment of inertia of the plane of flotation*, which is itself a *variable* quantity throughout the motion. It would seem that the Calculus of Variations might be advantageously applied to the question, or, at all events, Canon Moseley's paper might be made available, providing *we were to calculate the amount of probable error in assuming the plane of flotation constant within given limits.*

As the question stands, we do not know that a better and more simple method can be brought before the practical man than the following, which is due to the Rev. Dr Woolley:—

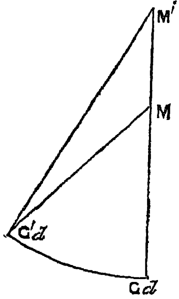

Fig. 11.

"Suppose $G_d\,G'_d$ to be an arc described by the centre of gravity of displacement, corresponding to the half-angle through which the vessel rolls, and let M, M′, be the limits within which the normals to the curve cut, G_dM, the former corresponding to the upright position of the vessel, G the centre of gravity of the vessel, then the time of rolling, supposing M to be fixed during the motion, is too great; and if M′ were the point of suspension, the time would be too small; but taking intermediate points, and calculating the time for each, supposed fixed, let T be the true time, α_1, α_2, α_3, &c., the errors, t_1, t_2, t_3, &c., the calculated times, then—

$$T + \alpha_1 = t_1$$
$$T + \alpha_2 = t_2$$
$$T + \alpha_3 = t_3$$
$$T + \alpha_n = t_n$$
$$\therefore \quad T = \frac{t_1 + t_2 + t_3 + \&c. + t_n}{n} - \frac{\alpha_1 + \alpha_2 + \alpha_3 + \&c. +.}{n}.$$ [3]

Now, since some of these errors are negative and some positive, we may make this result as small as we please, by taking n sufficiently great.

$$\therefore \quad T = \frac{t_1 + t_2 + t_3 + \&c.\ t_n}{n}, \text{ very nearly.}$$

When the distance between M and M′ is very small, as is the case in most vessels for a moderate amplitude, then the question is reduced to the case of a simple pendulum, the length of which is G_dM. Therefore K being the radius of gyration of the ship round a longitudinal axis through its centre of gravity,

$$T = \frac{\pi K}{\sqrt{g.G_dM}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(I.)}$$ [4]

K is obtained by multiplying each of the elementary weights of the vessel by the square of its distance from the horizontal axis through the centre of gravity, and extending the summation throughout the whole ship. Divide this result by the total weight of the ship when ready for sea, and extract the square root of the quotient, which gives K.[5]

We see from (I.), that the time of a natural oscillation varies directly as the radius of gyration, and inversely as the square root of the distance between the centre of gravity of the vessel and its metacentre. Hence, by increasing K, which may be done by moving the weights on board further from the axis about which the ship revolves, the time of oscillation is increased; also K remaining constant, if GM be diminished, T is also increased, and *vice versâ*.

Canon Moseley gives the following approximate result for the time of performing an oscillation:—

$$T = \frac{\pi K}{\sqrt{g\left(+GG_d + \frac{gk}{W}\right)}} = \frac{\pi K}{\sqrt{g\,G_dM}}. \quad \text{For } \frac{gk}{W} = MG_d.$$ [5]

Art. 11, formula (I.), where k represents the moment of inertia of the plane of flotation about one of its principal axes.

The Forces which act upon a Ship in motion, as they influence her general dimensions, form, and qualities.

The methods by which the displacement of a ship are found, and those by which the positions of her centres of gravity are determined, having been described, and the principles on which her stability depends having been

---

[2] See Moseley's paper.

[3] It would be a very easy matter to compare the time of a vessel's rolling through any angle with a pendulum whose length varies between the limits G_dM and G^dM'. For we have only to conceive a fine string suspended from A, and carrying a bob at G_d, and passing through an exceedingly fine aperture in a rod G_dM', the latter rod making a vertical motion=MM′ in the same time that G_d completes the arc $G_dG'_d$,—that is, much on the same plan as the motion of the slide-valve of a steam-engine. Indeed, it would not be difficult to make the point M′ describe the exact curve traced out by this point during the motion of the ship, providing that curve be calculated; we should then be in a position to learn accurately what error is made by assuming M to be the point of suspension.

[5] From a paper by the Rev. Dr Woolley.

Forces affecting a Ship in motion.

Laws of resistances.

pointed out, it is now proposed to consider the forces which affect her speed through the water.

It was at a very early period pointed out by mathematicians, that the velocity with which water will run out through a hole in the bottom of a vessel is the same as that acquired by a body falling from a height equal to the depth from the surface of the water to the hole. The truth of this has been at various times tested by many experiments, and has been confirmed by all that have been made. Euler, in his work, *Theorie Complette de la Construction des Vaisseaux*, took this as the basis of his investigations of the theory of the resistances which solid bodies moving in a fluid have to overcome. A passage in the English translation of his work is given thus:—

"We know, both from theory and experience, that the water contained in a vessel, whose height is $= h$, will run out through a hole in the bottom with the same velocity that a body falling from the same height, h, would acquire. And if the letter g denotes the height through which a body falls in one second, we also know the velocity will be such that it would run through a distance $= 2\sqrt{gh}$ in the same time. Since, therefore, this velocity is supposed $= c$, or $2\sqrt{gh} = c$, and, by taking the square, $4gh = c^2$; whence we have the height sought, $h = \frac{c^2}{4g}$; consequently, the force of the resistance which a supposed plane surface $= f.^2$ will experience by moving in water, with the velocity c, will be $= \frac{c^2 f^2}{4g}$; and by this force the surface will be acted on, in a direction contrary to its motion. Hence, we see that this resistance is always proportional to the square of the velocity, and also proportional to the area of the surface itself, so that by this means the resistance is perfectly determined."

If the direct resistance to the motion of a vessel through the water were not lessened by her form, it would, by this rule, be ascertained by finding the weights of a column of water, whose base is equal to her midship section, and whose height is equal to that from which a body must fall to acquire the velocity at which she is propelled, and the resistances of similar vessels when moved with the same velocity, would be proportional to their midship sections. The direct resistance, however, to any plane surface will be diminished by placing a triangular, or other form of body, before and behind it; and many experiments have been made on the form to be added, with a view to discover the law of the diminution of this resistance, and thus to be able to approximate to the form of least resistance. All attempts to reconcile the theory of the resistances on the oblique surfaces thus presented to the fluid with the observations by experiment, have as yet failed. Bossut[1] gives the theoretical resolution of the resistance on the sides of a wedge-shaped body as follows, and then shows that this is found by experiment not to be true with respect to bodies with sharp ends moving in water:—

Let ADB (fig.12) be an isosceles triangle, moving in a fluid of infinite extent in the direction of its height QD. The face AD is subject, according to theory, to a resistance in the direction FE perpendicular to itself, such that in calling π the perpendicular and direct resistance experienced by the half-base AQ. When moved with the same velocity as the triangle, we have force

$$FE = \pi \times \frac{AD \times (\sin ADQ)^2}{AQ \times (AD)^2}$$

$$= \pi \times \frac{AD \times AQ^2}{AQ \times AD^2}$$

$= \pi \times \frac{AQ}{AD}$; and in a similar manner we have, for the other force BD, force $fe = \pi \times \frac{BQ}{BD}$, $= \pi \times \frac{AQ}{AD}$. Resolving each of the two equal forces FE and fe into the two others, FH FK, and fh fk, the one perpendicular, and the other parallel to the base AD of the triangle, it is evident that the two forces equal, and directly opposed to each other, FK and fk, destroy each other, and that the triangle is simply acted on in the direction QD by one force $= FH + fh = 2\,FH = 2\,FE \times \frac{AQ}{AD}$ $= 2\pi \times \frac{AQ^2}{AD^2}$. Hence, if we call this force $2\,FH = p$, and call the perpendicular and direct force which acts upon the base AB, when moved with the same velocity as the triangle $= P$, we have $p = P \times \frac{AQ^2}{AD^2}$. Comparing this formula with his experiments, Bossut found the following results in four instances of experiments with different models:—

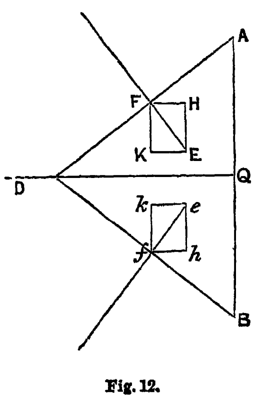

Fig. 12.

Forces affecting a Ship in motion.

Resistances on oblique surfaces.

Distinguishing No. of Model Experimented upon.	Angle of Incidence.	Value of p in Marcs	
		by Experiment.	by Theory.
9	45°	12·96 nearly	12
10	33° 41′	10·80 „	7·38 nearly
11	26° 34′	8·39 „	4·80
12	21° 49′	8·32 „	3·31 nearly

From the above it is seen that the results of theory differ further and further from those of experiment, the smaller the angle of incidence or the finer the angle of entrance of a ship is made. Further experiments have been made with a view to discover the law of this branch of the theory of resistances, but as yet without any results such as will enable any calculation to be made to determine beforehand, with any accuracy, the extent to which the resistance of a body of any given form will be diminished from that due to the base or midship section of the body. Even if a law were discovered for different angles of incidence, the difficulty of the investigation would still be great, when it is considered how constantly this angle varies in the form of the fore-body of a ship.

Resistances vary as the squares of the velocities, and are proportional to the surfaces.

Theory, therefore, fails to give any rule by which to ascertain, by any abstract calculation, the resistance of a vessel of any given form, and consequently to ascertain the velocity that she will obtain by the exertion of any given amount of power to propel her; and the naval architect is thus driven to ascertain these points by comparison with the results obtained from vessels of known form and power.

It has already been shown in the extract from Euler, that the resistances experienced by the same body, when moved at different velocities, vary as the squares of the velocities, and that the resistances of similar vessels, moved at the same velocity, are proportional to their surfaces or the areas of their midship sections. Many experiments have been made to test the accordance or otherwise of these theoretical deductions with the actual results obtained in practice. M. Bossut reported, as the result of the experiments conducted for the Royal Academy of Sciences at Paris in the year 1776, that the resistances of the same surface, moved with different velocities through a fluid infinite in extent, follow nearly the proportion of the squares of the velocities, and also that the perpendicular and direct resistances of several plane surfaces, moved with the same velocity, are very nearly proportional to the areas of the surfaces; and, consequently, that experiment and theory may be said to agree on these points. The experiments made in 1796 and 1798 in this country by the Society for the Improvement of Naval Architecture, and conducted by Colonel Beaufoy, lead to the same conclusion. These experiments were made with bodies of various forms, and at velocities varying from 1 to 8 nautical miles per hour. The relative proportion or degree in which the resistances and velocities varied in the bodies of different

[1] *Nouvelles Expériences sur la Resistance des Fluides*, Paris, 1777.

Forces acting on a Ship in motion.

forms differed comparatively slightly, being in some cases above the square or second power, and in other cases below it; in one instance it reached as high as the power of 2·2061, and in another instance as low as 1·7914, but the average of the results obtained from these experiments may safely be taken as corroborative of the theory.

Exception has been taken by some to the results of these experiments, because the bodies were entirely submerged, but the reasons for so conducting them appear to be stronger than those for conducting a series of experiments on bodies only partially submerged, and then subject to other influences than the action of the water through which they are passing. Deductions based upon the grounds thus established, as furnishing correct data on the subject of resistances, are of great practical value to the naval architect.

Propulsion of vessels by steam power.

The resistances, whatever they may be, of the same body, having been shown to be as the squares of the velocities, it follows necessarily that the horse-powers exerted to produce the different velocities will vary as the cubes of the velocities. This is evident, because the power is the product of the distance passed over, multiplied into the force exerted, while the distances vary directly as the velocities and the forces vary in the proportion of the squares. The origin and the truth of the formula in common use $\frac{V^3 \times \text{Mid. Sec.}}{\text{I.H.P.}}$ equal to a co-efficient C is therefore apparent; the resistances being in proportion to the areas of the midship sections; and I.H.P. being put to represent the indicated horse-power.

It is sometimes preferred to use a ratio of the displacement instead of the midship section, and as the ratio of the midship section of similar bodies is also expressed by the ratio of the cube root of the square of their cubical contents, this may be substituted in lieu of the midship section in the foregoing formula. It will then become $\frac{V^3 D^{\frac{2}{3}}}{\text{I. H. P}} = C$, and hence V, or any one unknown element in the formula may be found, all the others being known. A ready means of comparison between different ships is thus obtained. If the vessels are different in size, but mathematically similar, that is, if one is a type of the other, and the whole particulars of one are known, the velocity of the other, for any supposed amount of power, or the necessary amount of power to produce any proposed velocity, will be obtained.

The practical application of these principles to the propulsion of vessels by steam-power, which is always applied in the direction of the keel, would be easily carried out if the amount of power which is actually effective in propelling the vessel could be accurately ascertained separately from the power expended in working the parts of the engine itself, and in the friction. The total horse-power generated or exerted by the steam, is measured by the indicator, and is called the indicated horse-power; but engineers have as yet failed to discover any satisfactory method by which the effective can be separated from the gross horse-power. It is usual, therefore, to assume that, for every indicated horse-power, a given amount of effective power is exerted, and the gross power is argued upon as a measure of the effective power. In many cases this assumption is no doubt correct, but in many others it is open to great question, and results thus obtained must not be argued upon as by any means definite, or anything more than an approximation sufficiently accurate for most practical purposes.

The form of the engines and boilers to be used in the propulsion of a vessel is generally left by the naval architect to be determined by the engineers; but at the same time, the amount of power to be placed in the vessel, the weight and the positions of the centres of gravity, both vertically and longitudinally, of the machinery, must be duly considered and determined in concert with the naval architect. The form of the vessel at the place where the paddle-wheels, or where the screw are to act, also require special consideration on the part of the naval architect, otherwise the power exerted by the engine may be wasted, as it formerly was in churning the water when the paddle-wheels were boxed up in sponsons.

Forces acting on a Ship in motion.

The arrangements for the propulsion of vessels by the agency of the wind come within the province of the naval architect, and much consideration has been given to the subject in many works.

Resultants of forces acting on a ship under sail, and centres of effort.

When the ship is under sail, there are two forces acting on it—the one, the force of the wind on the sails, to propel the ship; and the other, the resistance of the water to oppose her motion. These forces, immediately the ship has acquired the velocity due to the strength of the wind, are equal, and, as is the case with all forces, may each be reasoned on as if acting only on one point of the surface over which its effect is diffused. This point is that in which, if the whole force were to be concentrated, its effect would be the same as when dispersed over the whole area: it is usual to call these, "resultants of forces," and the points on which they are supposed to act, "centres of effort."

Action of wind on the sails, and water on the hull.

From what has been before said, the resultant of the force of the wind on the sails, and the resultant of the force of the water on the hull, are equal; the one acting on the weather-side of the ship, in the direction into which the force of the wind resolves itself, and the other opposed to it, acting on the lee-side, in the direction into which the force of the water resolves itself; and their effect is necessarily in proportion to their distance from the centre of gravity. If they are equally distant, they will destroy each other, and the ship will remain at rest with respect to the line of its course; if the resultant of the resistance of the water passes before the resultant of the wind, the ship will turn to the wind; but if the resultant of the wind passes before that of the water, the effect will be the contrary, and the ship will fall off from the wind. In either case it will be necessary to equalize the forces, by the action of the water on the rudder, on its lee-side, to bring the resultant of the water more aft, and on its weather-side to destroy a part of the effect of the wind. This is the principle of the action of the wind on the sails, and of that of the water on the hull, with respect to the course of the ship through the water; and it is on these considerations only that the various alterations can be regulated, which it may from time to time be necessary to make in the trim either of the sails or of the ship; and hence the accurate determination of the positions and directions of these two forces is a point of great importance in naval architecture. The position of the centre of effort of the wind on the sails may be found under certain reservations; and that being known, enough is determined to lead to correct conclusions on the other circumstances attendant on the subject.

Centre of effort of wind before centre of gravity of ship, determines positions of masts.

In order to find the distance of the centre of effort of the wind on the sails before the centre of gravity of the ship, the moment of each sail is calculated by multiplying its area by the horizontal distance of its centre of gravity from that of the ship; the sum of the negative moments, or those abaft the centre of gravity of the ship, is then subtracted from the sum of the positive moments, or those before the centre of gravity of the ship; the remainder is then divided by the total area of the sails, and the result gives the required distance of the centre of effort of the wind on the sails before the centre of gravity of the ship. The situation of this point with respect to the length of the vessel must determine in a considerable degree the positions of the masts; for experience has proved that it is among the most essentially requisite good qualities of a ship, that she shall carry a weather-helm.

Effect and position of the rudder during continuous motion.

With respect to ships carrying a weather-helm, it may be assumed that the particles of water have a motion at the stern of the vessel, the direction of which forms an acute angle with the middle line of the ship produced aft, which angle will evidently be dependent on the fulness or the fineness of the after-part of the body, and on the angle which the line of the ship's course, or that of the lee-way, makes with the middle line of the ship; consequently, the

Forces acting on a Ship in motion.

inactive position of the rudder will be when it forms this angle with the middle line of the ship, that is, when the rudder is to leeward, and consequently, the helm a-weather. And this position should be the theoretic limit of the degree of weather-helm a ship should carry, as in any other position there must be a force acting on the rudder, which must increase the resistance the ship experiences in her passage through the water. A practical confirmation of the correctness of this principle, and of the fact that this generally advantageous position of the rudder is a-lee of the middle line of the ship, may be drawn from the common observation, that when a ship is in good trim, the helm, being a-weather, has a very perceptible tremulous motion, which must arise from the rudder being in a position in which it is not acted upon on either side by any constant force. This method of considering the direction of the flow of the water to the rudder considerably diminishes the estimate of the excess of its effect on the lee-side of the rudder over that on the weather. But there are several other considerations which operate in increasing the effect of the weather-helm. From the direction in which the water flows past the ship, there will be a much greater reduction of pressure on the weather-side of the rudder when the helm is to windward, and therefore a greater positive pressure on its lee-side to turn the ship, than will occur under the opposite circumstances, or when the helm is a-lee. Also, the broken and disturbed state of the water on the after-part of the weather-side of the ship, and the consequent various degrees of resistance it opposes, must lessen its effect when the helm is a-lee.

Experience confirms theseviews.

Weather-helm.

Ships with lee-helm leewardly.

It has been said to be proved by practice, that ships which carry lee-helms cannot be weatherly; that is, will fall faster to leeward than those which carry weather-helms. But though the fact is correct, the reason assigned is in some degree mistaking the effect for the cause. It has before been said, that a part of the force of the wind acts in driving a ship bodily to leeward; of course its effect will be greater or less in proportion to the lateral resistance opposed to it, and the ship which opposes less lateral and greater longitudinal resistance to the water than another, will in the same period of time have fallen farthest to leeward, and the line of her course will have made a larger angle with her middle line, by which the effect of the water on the after-part of the lee-side is increased, while that on the fore-part, both of the lee and weather sides, is diminished, and the helm must consequently be kept less a-weather. A practical proof of the correctness of this reasoning may be drawn from the practice of the older class of merchant-vessels, which are generally, from form, more leewardly than men-of-war. They have their fore-mast placed much nearer the centre of the ship than is usual in sharper and finer formed bodies. This has evidently arisen from the operation of the cause above mentioned, which has shown that they require the resultant of the effort of the wind on the sails to be proportionately farther aft to insure their carrying a weather-helm. From this reasoning it is evident that, under some circumstances, it may be the leewardliness of the ship which causes her to carry a lee-helm; and that when such is the case, the defect might be remedied, not only by the usual methods of placing the masts farther aft, and altering the draught of water, but by increasing the lateral resistance by the addition of false keel, or by greater depth in the water.

Effect mistaken for cause.

Disadvantage of lee-helm.

There is another disadvantage arising from a ship's carrying a lee-helm, which is, that the action of the water on the weather-side of the rudder acts in conjunction with the force of the wind in forcing the ship bodily to leeward; while, on the contrary, when the helm is a-weather, the action of the water on the rudder is in opposition to the force of the wind. The ardency of a ship, which is her tendency to fly to the wind, depends on the relative positions of the resultant of the effort of the wind on the sails, and the resultant of the resistance of the water on the hull. The position of the centre of effort of the wind on the sails is calculated under the supposition that the sails are plane surfaces, and equally disposed with regard to the longitudinal axis of the ship; but when a ship is on a wind, as the force of the wind acts in a direction oblique to the surface of the sails, a greater proportion of the sail is carried to leeward of this axis, and the whole sail assumes a curved surface, the curvature of which increases from the weather to the lee side. From these circumstances, the centre of effort is in fact carried gradually farther aft as the action of the wind takes place on the sails. Also, as the force of the wind inclines the ship, the centre of effort of the wind on the sails is carried, by this inclination, over to the lee-side, by which, as also by the effect produced on the resultant of the water, which has been before mentioned, the distance between them is farther increased. It therefore appears that, the quantity and disposition of the sail set remaining the same, the ardency will increase as the force of the wind increases, and diminish as that force diminishes. The defect of a vessel carrying a lee-helm may be lessened by those means of trimming either the sails or the ship, which will tend to increase the distance of the resultant of the water before the centre of effort of the wind. Great caution is necessary before altering the position of the masts with a view to remedy this defect, because her working quickly depends on the proportion of sail before and abaft the axis of rotation, and not on the position of the centre of effort of the whole surface of the sails. The limits of this article will not permit the subjects of masting, or rigging, or sail-making to be gone into. Much valuable information on the subject of the effect of the wind upon the sails, the angle of lee-way, the position of the centre of effort, and other points, will be found in the article SEAMANSHIP.

Forces acting on a Ship in motion.

Sails assumed to be plane surfaces.

Effect of their curvature.

Of increase of wind.

Pitching and scending.

The motion of pitching and scending is generally the most violent action to which a ship is subjected, and the most injurious, both to the connection between the parts of her structure and the velocity of her sailing. It is the longitudinal motion caused by the variable support afforded to the body by the waves as the vessel meets and passes over them; pitching being dipping of the bows into the water, and scending, the dipping of the stern. To obtain ease of motion in this respect, Mr Henwood advocated, in a paper published in the *Papers on Naval Architecture*, that the after-part of the ship, or that part abaft the centre of gravity, should be constructed so as to have precisely the same cubic contents as the fore-body, and that its centre of gravity should be at the same distance from the centre of gravity of the ship as that of the fore-body. The disposition of the weights, and especially of the masts, influences this motion in a powerful degree; because, though the weights in the fore and after bodies may balance each other while at rest, a greater weight, perhaps at a less distance, balancing a less weight at a greater distance; yet, when the ship is set in motion the balance will no longer hold, because the moments of the weights in motion will be according to the squares of their distances from the common centre of gravity. If a vessel pitches heavily, the moments of the weights forward are too great, and the contrary if she scends heavily abaft. An uneasy motion in pitching is much more common than in scending, and this no doubt arises from the generally very forward position of the fore-mast, especially in men-of-war. The importance of a little attention to this subject on the part of naval men will be at once apparent, when it is considered that the effect of moving or placing 5 tons at a distance of 120 feet from the centre of gravity of the ship is represented by the number $72{,}000 = 120^2 \times 5$, while it would be necessary to move 720 tons to a distance of 10 feet on the opposite side

Forces acting on a Ship in motion.

of the centre of gravity to produce the same effect on the pitching and scending motions of a ship.

Rolling.

The rolling motion of a ship is caused more by the undulations of the waves than by the shock of a wave striking the side of a ship. The principles on which the rolling of a vessel depends have been already investigated, and a few practical remarks will only be added here. The remark is common, and it is true, that the crank ship is the easy ship—that is, the more readily a vessel rolls, the easier will be the rolling motion. Mr Wilson, late of the Admiralty Office, in an able article in the *Papers on Naval Architecture*, says, "If stability is too great, the most efficacious way of diminishing the rolling is to bring up the ballast, because it raises the centre of gravity, and it increases the distance of the centre of oscillation from the axis of rotation. The ballast removed from near the keelson to the wings, even if placed as high as the deck, is as far from the metacentre as when it was in the hold, and consequently its weight multiplied into the square of that distance is the same as before; the rollings, therefore, will be slower." The cables, shot, stores, &c., in any ship, if placed near the side, while this will not affect the stability, will increase the distance between them and the axis of rotation, and will consequently lengthen the time of vibration. Mr Wilson proceeds to say, that it is by no means a difficult task to reduce a ship of extraordinary stability, which is always an uneasy one, to a state of easy rolling by increasing the masts and yards, and increasing the weights above and putting them in the wings, and removing some ballast, if she has any on board.

Fincham, in his *History of Ship-Building*, gives a remarkable instance of the extent to which the qualities of a ship may be influenced by other circumstances than her form. "The Mutine, an experimental brig, built to compete with others, was beaten on the first experimental cruise, but she afterwards beat the others, alterations having been made in the trim of her sails and in her stowage. After the alterations, instead of rolling the shot out of the racks and the wind out of the sails, as before, she rolled little, and neither deep nor quick. At first her weights were carried too low down."

Motion as influenced by general dimensions or form.

Length.

The motions of a vessel are much affected by the proportions which the general dimensions bear to each other. An increase of length gives an increase of displacement, or if this is not desired, it allows of finer lines forward and aft, and it also increases the stability and the resistance to lee-way. The power of turning, tacking, wearing, or making any other change in her course, is lessened by an increase of length; but this effect may be much modified by diminishing the amount of fore-foot, or of dead-wood forward, which will alter the position of the resultant of the action of the water, and will consequently also require a corresponding alteration in the amount or position of the forward and aft sails. A vessel need not necessarily pitch more heavily on account of any increase of length, but it is necessary in long vessels to take greater care that the weights of the fore and aft bodies are properly balanced in regard to their moments. It will be evident that the moments of small weights when placed well forward or aft, become very much greater in long vessels, when it is considered that all weights are multiplied by the squares of their distances from the centre of gravity of the ship for their moments.

The friction upon the sides of a vessel, from any additional length of parallel body amidships, appears to be very trifling, if we may judge from the results of cases where vessels have been cut in midships and lengthened, without any other alteration in their form having been made. The following is a statement of the results obtained by lengthening the Candia, a vessel belonging to the Peninsular and Oriental Company, by putting 35 feet into her amidships:—

	Trial before being lengthened, May 31, 1855.	First trial after being lengthened Aug. 8, 1857.	Second trial after being lengthened, Aug. 12, 1857.
Draft forward	18 ft. 6 in.	18 ft. 2 in.	18 ft. 2½ in.
„ aft	18 ft. 6 in.	19 ft. 5 in.	19 ft. 7 in.
„ mean	18 ft. 6 in.	18 ft. 9½ in.	18 ft. 11 in.
Area midship section	536 feet	551 feet	556 feet
Displacement	2,435 tons	3,036 tons	3,069 tons
Nominal horse-power	450	450	450
Indicated horse-power	1,415	1,250	about 1,400
Revolutions	34½ to 37	31	33
Pressure	22 lb.	16 lb.	20 lbs.
Vacuum	26½	26	26½
Speed	12,651	11,675	12,443
Pitch of screw	20 feet	21 feet	21 feet
Diameter of ditto	15 ft. 6 in.	15 ft. 6 in.	15 ft. 6 in.
Blades	3	3	3

Breadth.

By increasing the breadth amidships, as well as the average breadth throughout the whole length of the vessel, while the length and depth are kept the same as before, the stability, which varies as the cube of the breadth, is increased. As the angular momenta of the weights, estimated from the axis of rotation, vary as the squares of their distances from that axis, and the momentum of the action of a wave is increased in the same proportion, therefore the increase of stability is accompanied by increased violence in the motions, and consequent increased strain on the combinations and materials of the structure, and especially danger to the masts, by which the safety of the vessel may be compromised. The stability of a ship of war, being the quality on which the efficiency of her armament is essentially dependent, and which also, by enabling her to carry a press of sail in circumstances of danger, as a lee-shore, or an enemy of superior force, is essential to her safety; the only limit to its increase is involved in the consideration of easiness of motion. But if this consideration be neglected, and the breadth be such that the moment of stability in proportion to the moment of sail is so large, or of such sudden increase, that the masts are endangered or the combinations of the structure prematurely destroyed, the object for which a large moment of stability was desirable is frustrated. The breadth, therefore, is limited by easiness of motion. The best mode of insuring stability is to give a large area and great fulness and similarity of form immediately above and below the average water-line, as by this means the centre of gravity of the displacement will be kept at as short a distance as possible below the surface of the water.

Effect thereof on the stability of a ship.

Depth.

The depth of a ship, or her draught of water, may vary according to local circumstances or the objects for which she is to be employed, or by a judicious arrangement of her other proportions and of her form, and the positions of the centre of gravity. Good ships may be produced varying considerably in the proportions of their depth to their breadth.

Alteration of seat in water from consumption of stores.

An important consideration connected with the forming the design of a ship is involved in the gradual alteration of the vessel's seat in the water from the consumption of stores. It is not only essential that a ship should be possessed of stability combined with easiness of motion, be weatherly and quick in manœuvring when she is stored and completed for foreign service as a ship of war, or fully laden as a merchant-ship, but it is equally essential that she should be possessed of these qualities towards the expiration of her cruise, or on her return light from her voyage.

The loss of stability which results from the diminution of draught of water cannot be compensated by a proportionate arrangement of sail, without incurring other evil consequences. If the quantity of sail, which at all times is comparatively small in a merchant-ship, be lessened, the wind

Forces acting on a Ship in motion.

on the increased hull might so counterbalance its effect that she would be utterly unable to beat off a lee-shore, or make any way on a wind.

causing diminution of stability, and increased uneasiness.

A ship is not only subject to a loss in stability when lightened, but becomes laboursome, on account of top-hamper: her rolling motion is more violent as her diminished depth in the water decreases the resistance which is opposed to the inclination, and she also generally becomes more leewardly, owing to the difference made in the resultant of the resistance, the diminution of the lateral resistance, and of her power of carrying sail.

Difference of draught of water.

It is almost a universal custom in all vessels to give a greater draught of water abaft than forward. Occasional attempts have been made to discontinue this practice, as involving a supposed unnecessary increase in the water required for floating a ship; but the increased draught of water for the after-body has been reverted to as essentially requisite in practice.

Its advantages.

There are several minor advantages which result from this arrangement; such as the more easy and unchecked flow of the water to the rudder, and its consequent increased effect in governing the motions of the ship; also the diminution of the negative resistance which the vessel would otherwise experience from the greater difficulty with which the flow of water would fill the vacuity caused by the passage of the vessel, if the fulness of the after-body were such as would be required to preserve an even draught of water; and again, the adjustment of the resultant of the resistance of the water to that position of the masts which experience has determined to be requisite for the facility of manœuvring the sails. But the principal reason for the inequality in the draught of water appears to be the advantage which results from it to the more easy regulation of the motions of the vessel by an adjustment of the resultant of the resistance of the water on the lee-side when on a wind.

Designing of vessels.

The considerations which lead to a settlement of the general dimensions of a vessel, and which must vary greatly according to the purpose for which she is intended, having been touched upon, it is proposed to give an outline of the course pursued in designing the form, or making the *constructive drawing*, as it is termed, of any vessel. Three plans are required in all designs of vessels—the body-plan, the sheer-plan, and the half-breadth plan (see Plate III.) The form of the midship section, or a vertical cross-section at the point of greatest breadth, is generally the first portion of a ship that is designed; the outline of the sheer-plan may then be delineated, and after that the half-breadth plan may be begun. The vessel is supposed to be divided into a certain number of horizontal sections, and these are represented by the lines on the sheer-plan, marked 1st, 2d, 3d, 4th, and 5th water-line. The sheer-plan is either a vertical longitudinal section, or a side-plan of the ship, and on it may be delineated any points in her length or height. On the half-breadth plan are delineated the outlines of the horizontal sections previously referred to, and marked water-lines. These horizontal sections may either be parallel to the keel or to the intended water-line of the vessel if she is intended to draw more water abaft than forward. When parallel with the keel, they are sometimes called level-lines. The midship section is not necessarily in the middle of the length; it is called dead-flat, and is always marked as shown on the plate. The length of the vessel is divided into any desired number of sections, and these sections are marked forward and aft from dead-flat with distinguishing letters and figures. The water-lines being also drawn upon the midship section or body-plan, the form of the body at each section in the half-breadth plan is obtained by finding the distance from the centre-line at each water-line, and transferring it to the body-plan, showing the sections of the fore-body and of the after-body on different sides of the middle-line. In addition to these lines, the vessel is supposed to be cut into various longitudinal sections, at given distances from the centre-line; these lines of sections are shown on the half-breadth and body plans; and the form of the body where these cut the exterior surface of the ship are shown on the sheer-plan; they are marked 1v, 2v, 3v, in all the plans. The sections represented in all these plans must be fair and of easy curvature, and many little alterations will probably require to be made by the draughtsman, to get them to coincide.

The constructor or designer is now in a position to test his work by making the necessary calculations. These will be comprised in ascertaining the area of the midship section, the area of the load-water section, the displacement, the positions of the centres of gravity of these two sections, and also the position of the centre of gravity of the displacement.

The areas of the two sections, and the positions of their respective centres of gravity, are required to be determined, on account of the influence of these areas and their positions on the content of the displacement, and the position of its centre of gravity, and also in consequence of their influence on the stability of the ship. If the results of these calculations do not accord with the intentions of the constructor, or are inadequate to the development of his design, he must make such alterations in his curves or in his dimensions as he may consider necessary, before proceeding further with his design; and if he shall have sufficiently informed himself on the theory of ships, he will be enabled to do so with considerable confidence at this stage of his progress, as to the final result of his work.

These calculations are no doubt laborious, but there is no difficulty in them, and any moderately educated subordinate may soon be taught to assist greatly in working them out. Space will not permit an example to be given here; but the labour will be greatly facilitated by tabular forms, and examples will be found in Mr Peake's work on Ship-building, and in one of a series of articles on Ship-building in the *London Mechanics' Magazine* for 1859.

Before the design can be considered complete, it is necessary to ascertain the weight of the hull and of the whole of the proposed contents of the ship, and compare these with the calculated displacement. It is seldom that these weights can be obtained with perfect accuracy, and it is therefore scarcely necessary in practice to go to any undue labour to bring out results to fractions.

Scale of displacement.

It is usual to delineate the results of the calculations of the displacement in the form shown in Plate IV. The curved line representing the displacement of the ship at any draught.

Proportion of circumscribing parallelopipedon.

As a guide in commencing a design, it is also usual, and very useful, to know what proportion the circumscribing parallelopipedon will bear to the body of the ship—that is, multiply the intended length, breadth, and draught of water of the ship together, and deduct such portion as will leave a body of a form of any desired fineness. The amount to be deducted, or the decimal fraction by which the parallelopipedon is to be multiplied, varies, of course, for every class of ship.

Influence of form on rolling.

The form of the midship section, and of the other sections near it and therefore influenced by it, affect the question of rolling, by affecting the position of the centres of gravity of the displacement and of the ship and her weights; but there is no doubt but that if it were possible to keep these centres of gravity relatively in the same position with different forms of bodies, the rapidity and extent of rolling would still be influenced by the form, and be different. No rules can be laid down definitely on this subject; but ships with a form of midship-section approaching a semicircle have a bad reputation for rolling; as also those with a very rising floor, if accompanied with great beam, or such beam that the half-breadth exceeds the draught of water by more than 1 or 2 feet. A flat floor is also injurious, as tending

Form and Tonnage of Vessels.

to keep the centre of gravity of the displacement too low. Some good midship-sections of ships of various classes will be found in Fincham's *Outlines of Ship-Building;* but the great length now given to the fore and after bodies of ships renders the effect of the form of the midship-section much less influential on the general properties of a vessel than formerly, when the proportion of length was so much less.

Forms of water-lines. For the water-lines of vessels no definite instructions have been attempted to be laid down that have been of any practical value. A few general remarks may be made, to the effect that certain degrees of sharpness seem suited for different degrees of speed—the faster the vessel, the finer are the lines required; and if a moderate amount of power only be applied to a vessel, so that her speed cannot be great, it will be of little avail to give her finer lines than those suited to her actual speed. Hollow water-lines below the surface of the water seem to be beneficial for high velocities, but not at the water-line or above it, as the waves seem then to dash into the hollow and obstruct the vessel's way, by their being confined and not passing freely away.

Vertical lines. In all the plates given with this article, vertical lines are shown. The form of vessels, in respect of the sections shown by these lines, would appear to have been too much neglected by naval architects. It is considered that the form of vessels at the bows or at the stern, may be looked upon as made up of lines representing a wedge with its face vertical, and dividing the water sideways, combined with other lines representing an inclined plane, as in the Thames barges. Bodies of a wedge form were experimented upon by Colonel Beaufoy, as also others, with an inclined plane forward and aft to compare with them, and the results were decidedly in favour of the inclined plane; the inclined plane in the after-body having been proved decidedly superior.[1] The bodies which gave these results were those designated *m, b, m,* and *p, b, p,* and the experiments were conducted at the surface, and not with the bodies totally submerged.

Tonnage. The tonnage of a ship is her assumed capacity for carrying cargo of any description. The capacity or space required for a ton of iron being very different from that required for a ton of light goods, a certain number of cubic feet are necessarily taken as the measure of a vessel's tonnage. An empirical rule, founded upon obsolete proportions of a vessel's dimensions, continued in use for many years, serving as a measurement, not only of builders' tonnage, but also of the register tonnage for regulating the dues payable by the ship. This rule is still continued by builders as the measure by which ships are bought and sold; but as the price per ton may be varied in the same proportion as the dimensions, and are known at the time of purchase or sale, no evil results arise from this adherence to the old rule, however far the measurement may be from the truth.

This rule for old or builders' measurement was established by act of Parliament in the reign of George III. It enacted, that "the length shall be taken in a straight line along the rabbet of the keel of the ship, from the back of the main stern-post to a perpendicular line from the fore-parts of the main-stem under the bowsprit. The breadth also shall be taken from the outside of the outside plank, in the broadest part of the ship, either above or below the main wales, exclusive of all manner of doubling planks that may be wrought upon the sides of the ship." If the ship be afloat, the directions are, "to drop a plumb-line over the stern of the ship, and measure the distance between such line and the after-part of the stern-post, at the load-water mark; then measure from the top of the said plumb-line, in a parallel direction with the water, to a perpendicular point immediately over the load-water mark at the fore-part of the main-stem; subtracting from such admeasurement the above distance, the remainder will be the ship's extreme length, from which is to be deducted 3 inches for every foot of the load draft of water for the rake abaft; from the length, taken in either of the ways above-mentioned, subtract $\frac{3}{5}$ths of the breadth taken as above, the remainder is esteemed the just length of the keel to find the tonnage; then multiply this length by the breadth, and that product by half the breadth, and dividing by 94, the quotient is deemed the true contents of the lading."

The existing act for ascertaining the tonnage is a great improvement upon the above, and its directions are as follow:—Divide the length of the upper-deck, between the after-part of the stem and the foremost part of the stern-post, into six equal parts. Depth,—at the foremost, middle, and aftermost of these points of division, measure in feet, and decimal parts of a foot, the depths from the under-side of the upper-deck to the ceiling at the limber-strake. In case of a break in the upper-deck, the depths are to be measured from a line stretched in a continuation of the deck. Breadths,—divide each of these three depths into five equal parts, and measure the inside breadths at the following points; viz., at $\frac{1}{5}$th and at $\frac{4}{5}$ths from the upper-deck of the foremost and aftermost depths, and at $\frac{2}{5}$ths and $\frac{4}{5}$ths from the upper-deck of the midship depth. Length,—at half the midship depth, measure the length of the vessel from the after-part of the stem to the foremost part of the stern-post; then to twice the midship depth add the foremost and aftermost depths for the sum of the depth; add together the upper and lower breadths, at the foremost division, three times the upper breadths and the lower breadth at the midship division, and the upper and twice the lower breadth at the after-division, for the sum of breadths; then multiply the sum of the breadths by the sum of the depths, and this product by the length, and divide the final product by 3500, which will give the number of tons for register. If the vessel have a poop, or half-deck, or a break in the upper-deck, measure the inside mean length, breadth, and height of such part thereof as may be included within the bulkhead. Multiply these three measurements together, and dividing the product by 92·4, the quotient will be the number of tons to be added to the result as above found. In order to ascertain the tonnage of open vessels, the depths are to be measured from the upper edge of the upper strake. In vessels propelled by steam, the tonnage due to the cubical contents of the engine-room is to be deducted from the gross tonnage thus found. It is enacted that the tonnage due to the cubical contents of the engine-room shall be determined in the following manner; that is to say, measure the inside length of the engine-room in feet, and decimal parts of a foot, from the foremost to the aftermost bulkhead, then multiply the said length by the depth of the ship or vessel at the midship division aforesaid, and the product by the inside breadth at the same division, at two-fifths of the depth from the deck, taken as aforesaid, and divide the last product by 92·4, and the quotient will be deemed the tonnage due to the cubical contents of the engine-room.

Among the plates will be found vessels of the highest character of the present day. The Pera of the Peninsular and Oriental Company's fleet is a well-known vessel, and one whose results are looked upon as of the highest character; and if the form of her body, as shown by the vertical lines on the sheer-plan, be examined and compared with those of any of the other vessels, it will be seen that she excels in this particular. The kindness of the different owners and builders in permitting the lines of their different vessels to be published has been great, and it is to

[1] Beaufoy's *Nautical and Hydraulic Experiments,* Introduction, p. 43.

Performances.

be hoped that so much public spirit as is now manifested in this respect may be rewarded by still further improvements upon the forms of vessels.

The clipper sailing-ship Schomberg, represented in Plate III., is a specimen of a first-class Aberdeen clipper, built by Messrs Hall of Aberdeen.

The Lord of the Isles is a very fine iron vessel, built by Messrs Jn. Scott and Company of Cartsdyke, near Greenock. Although a sharp ship, she carries a good cargo of weight and measurement goods combined. On her first voyage from Clyde to Sydney she had 1300 tons of weight and measurement cargo on board, and made the passage in 70 days—a passage which, it is believed, has not yet been surpassed. Her register tonnage is $691\frac{23}{100}$ tons; and her tonnage, by builders' measurement, is 770 tons. She also made a passage from Shanghae to London in 87 days, with 1030 tons of tea on board. On one voyage she averaged 320 nautical miles for five consecutive days; and on her last voyage to China, in crossing the N.E. trades, her average way was over 12 knots.

Plates V. and VI. represent the rival yachts Titania and America, when the prize was carried off from all England by the latter. The sections of the vertical lines are shown upon the drawings of both of these yachts; and if the vertical lines on the sheer-plan of the one are traced and laid upon those of the other, a marked difference in favour of the America will be apparent.

Plate VII. is a representation of a paddle-steamer, the Delta. The engines in this vessel were taken out of a vessel of 500 tons, and put into the Delta, of nearly four times this tonnage, and the result is a specimen of what may be achieved by fine lines with a judicious application of power; the larger vessel having nearly a knot more speed.

Plates VIII. and IX. represent the Great Eastern, and from the fineness of her lines there can be no doubt of her success, if the engines do their duty.

Plate X. is a representation of the Bremen, a vessel whose performances have been such as to attract special attention, and to lead the Committee appointed by the British Association for the Advancement of Science to make the following report concerning her:—

"This Committee are assured, on authority which they believe to be unquestionable, that a certain vessel, the Bremen,[1] of 3440 tons displacement at the time of trial, propelled by engines working up to 1624 indicated horse-power, attained the speed of 13·15 nautical miles per hour. Now, if we estimate the dynamic duty thus performed by the formula $\frac{V^3 D^{\frac{2}{3}}}{\text{Ind. H.P.}} = C$, we shall hav the co-efficient, $C = \frac{(13{\cdot}15)^3 \times (3440)^{\frac{2}{3}}}{1624} = \frac{2274 \times 227{\cdot}88}{1624} = 319$, and this co-efficient of dynamic duty, resulting from the mutual relation of displacement, speed, and power, appears, from the statements which have been communicated to this Committee, nearly 50 per cent. higher than that realised by the average performance of the steamships of the present day. The following are the co-efficients of dynamic duty deduced by the foregoing rule from the performances of mercantile steamers of high repute, of which the trial data have been communicated to this committee, viz. 325, 294, 291, 288, 259, 248, 231, 230, and 204, and many others below 200.

"This Committee, therefore, regard the Bremen as being a felicitous exemplification of naval architecture as respects type of form adapted for easy propulsion; and as we conceive that the promulgation of some of the constructive elements of this vessel may be of public importance, we are happy in being authorised and enabled, by Messrs Caird and Company, of Greenock, the constructors of the ship and of the engines, to communicate to the British Association the following statistical data as to the elements of construction of the Bremen:—

Performances and Tonnage.

Length between perpendiculars of stem and rudderpost		318 feet.
Breadth of beam		40 „
Depth of hold		26 feet.
Mean draught of water at the time of trial		18 ft. 6 in.
Displacement (D) at trial draught		3440 tons.
Area of maximum immersed section (A) at the trial draught		606 sq. ft.
Distance of maximum section (A) measuring from the stem		159 feet.
Constructors' load draught	forward	18 feet.
	aft	19 „
Displacement at constructors' load draught		3440 tons.
Rate of ships' displacement at constructors' load draught		25 tons per inch.

Data for laying off Peake's curve of sections.	Area of immersed vertical section at the distance of $\frac{1}{8}$ length measuring from stem			256·5 sq. ft.
	Do. $\frac{1}{4}$	do.	do.	486 „
	Do. $\frac{1}{2}$	do.	do.	606 „
	Do. $\frac{3}{4}$	do.	do.	489 „
	Do. $\frac{7}{8}$	do.	do.	253·5 „

Data for laying off curve of Displacement.	Displacement at draught of 4′ $7\frac{1}{2}$″, being $\frac{1}{4}$ load draught	300 tons.
	Displacement at draught of 9′ 3″, being $\frac{1}{2}$ load draught	1165 „
	Displacement at draught of 13′ $10\frac{1}{2}$″, being $\frac{3}{4}$ load draught	2240 „
	Displacement at draught of 18′ 6″, or load draught	3440 „

"The foregoing data afford all the particulars required for the construction of Peake's curve of vertical sections, whence may be deduced the position of the vertical line passing through the centre of gravity of displacement, and also the positions of the centre of gravity of the fore and aft bodies respectively.

"It will be observed, from the foregoing data of the constructive elements of the Bremen, that the maximum immersed section is at the middle of the length, and that the vertical sections are in such ratio to each other, with reference to their respective positions, that the curve of vertical sections will be a close approximation to a parabola.

"The ratios deducible from the foregoing particulars of constructive data, combining Peake's curve of immersed vertical sections with the curve of displacement, will give a close approximation to the type of form of the immersed hull.

"The engines of the Bremen consist of two direct-acting inverted cylinders, 90 inches diameter and 3 feet 6 inches stroke, fitted with expansion-valves capable of working expansively to a high degree. All parts of the engines are felted and lagged with wood wherever practicable, the lower 16 feet of the funnel being surrounded by a casing forming a superheating chamber, the steam entering at the lower end, and passing off at the top into the steam-pipes leading to the cylinders.

"On the important question as to the extent to which the ordinary smooth-water trial of a steamer affords a criterion of the general average performance that may be expected of the vessel at sea, this committee has not been able to obtain such an extent of returns of the comparative smooth-water trials and sea performances of the same ships as enable them fully to respond to this part of the inquiry, and they refrain from expressing any speculative opinion, because they have adopted the principle which they desire to recommend to the notice of the British Association, that shipping improvement is to be discovered by statistical record and analysis of the constructive elements of ships that have practically shown themselves to possess good sea properties, rather than by assuming the mere theories of opinionative speculation, from whatever source such opinions may emanate; in short, that experience of actual performances at sea, statistically recorded and utilized by being made the basis of comparison, is the most reliable base on which to construct an inductive system of progressive improvement in naval architecture and marine-engine construction. This committee, however, have much satisfaction in being enabled to commence this inquiry by recording the sea performance of the before-mentioned vessel Bremen, on a passage from Bremen Haven to New York and back, during the months of June and July last, during the whole of which passages indicator-cards were frequently taken, and the indicated working power of the engines ascertained. On the out-passage the mean displacement was 2878 tons, the mean indicated horse-power was 1078, and the mean speed 10·28 knots per hour, giving a coefficient by the formula referred to = 204; but on the return-passage the mean displacement was 2990, the

[1] The Bremen is referred to as being the vessel which gave the highest co-efficient of dynamic performance of any vessel which was brought before the Committee, and of which the statistical data of construction were also given in a complete form.

Performances.

mean indicated horse-power 1010 and the mean speed at the rate of 11·92 knots per hour, giving a co-efficient = 348. Hence, the mean co-efficient of the out and home passage = 276, being about 13 per cent. below the co-efficient (319) obtained on the smooth-water test-trial of the ship. The state of the weather and the sea was also recorded daily: it appears to have been adverse on the out passage, but favourable on the home passage. The committee are therefore of opinion, that by following up this course of statistical record of the smooth-water trial and subsequent sea performances of ships respectively, a tabular statement might be compiled, showing the probable ratios of the coefficients of smooth-water and sea performance, corresponding to the various rates of speed for which steamers may be respectively powered, whence the smooth-water test-trials of ships may be made available as approximately indicative of the sea service capabilities of ships as respects their dynamic properties.

"Such are the statistical data of the constructive elements and dynamic capabilities of the Bremen; and if all steam-vessels engaged in the mercantile transport service of Britain were equally effective as respects the mutual relations of displacement, speed, and power; that is, capable of producing a coefficient of dynamic capability = 319, by the formula referred to, it is probable that the prime cost expenses of steamship transport per ton weight of cargo conveyed on long passages would, on the aggregate of the foreign trade of Britain, be reduced not less than 25 per cent. as compared with the prime cost expenses incurred by steam-vessels of the average dynamic capability in present use."

Tabulated results of the performances of many vessels will be found in the article Steam Navigation; but the following results of the trials in smooth water of four of the vessels, whose lines and dimensions are given in the plates, may be quoted here:—

Name of ship.	Draught of water.	Indicated Horse-power.	Speed in knots.
	ft. in.		
Delta	15 0	1612	14·609
Ceylon	18 6	2054	13·340
Pera	18 3$\frac{1}{4}$	1373	12·633
Nubia	17 3	1422	12·149

Plates XI., XII., XIII., and XIV. are specimens of very fine vessels in the fleet of the Peninsular and Oriental Company. The Pera is especially celebrated for her performances, as also the Ceylon. The following table is interesting as showing the performances of the Nubia on her actual voyages at sea:—

Materials used in Ship-Building.

MATERIALS USED IN SHIP-BUILDING.

Import-ance of a knowledge of the pro-perties of materials.

Nothing can be more important to the naval architect than a thorough knowledge of the properties of the materials with which he has to deal. He requires this to enable him to dispose them to the greatest advantage, and with the least possible expenditure; and thus to produce a well-proportioned structure of great and uniform strength. The introduction of iron as a material for ship-building has enlarged this field of inquiry, and has led to much discussion as to its merits in comparison with those of timber.

Timber.

The properties of timber will be first considered. A lengthened examination into the nature and qualities of the different varieties used in ship-building cannot, however, be attempted here, as the space which can be allotted to the subject will not admit of more than a few practical observations. Deterioration and decay, in timber-built ships, may result either from the decay to which timber itself is subject, in common with all organic matter, and which may be hastened or retarded according as destructive or preservative influences are brought into action; or they may be the consequences of an injudicious combination of destructive agents with the inorganic compounds of the timber, thus inducing not only premature but unnatural decay. All large masses of timber in close contact are subject to deteriorating influences, such as a high degree of temperature, an increase of moisture, or a want of free circulation of air. These and other agencies, by promoting fermentation, lead to the first stage of decomposition, whereas the reverse of these conditions would in like manner retard its progress. Moisture as well as heat is necessary to produce fermentation, but when heat and the other agencies are at work, moisture will generally be found to exist, either left in the timber itself, or absorbed by it from the atmosphere.

Durability.

Dry-rot.

Decay of timber, when accompanied by the growth of fungi upon its surface, has received the name of *dry-rot*. This term was probably applied to it in consequence of the peculiarity, that wood so decomposed becomes a dry friable mass without fibrous tenacity, the parasitical fungi robbing the timber of its substance to support their own growth. In general, decay, when it takes place in this particular form, may be traced to imperfectly seasoned material, and the inference may be drawn with a considerable degree of probability, that the natural juices of the timber are necessary to the growth of fungi, and consequently that if these juices could be entirely abstracted or destroyed, this species of decay might be prevented. It does not follow that the presence of any of these juices will necessarily produce dry-rot, should the circumstances in which the timber is placed be such as to tend to their dispersion, or to their remaining in a dormant state. But as they do undoubtedly remain in much timber that is considered seasoned, any alteration of circumstances to prevent a free circulation of air, to lead to a deposition of additional moisture, and at the same time to an increased temperature, will in all probability induce the growth of fungi, and cause the destruction of the timber.

In ships, the frequent presence of these injurious elements must necessarily tend to produce fermentation. But though these facts are perfectly well known, it is remarkable how little attention has been paid to the necessity of a free circulation of air upon the timber of such parts of a ship as are below the surface of the water. This may be effected in various ways, though it is doubtful whether in all cases the current of air produced by natural causes would induce a sufficiently rapid circulation. This subject was forcibly brought before the Admiralty by Mr Creuze in 1827, but was not taken up or acted upon. In the navy, the decrease of expense which would be occasioned by any increase of durability in ships, laid up in ordinary, would be great; and in reality, with proper care and arrangements, there is no reason why the timbers of a ship so situated should not be almost as durable as the same wood employed in houses and other structures. The expense caused by decay is even greater in ships than in houses, yet the attention paid to the subject has been in an inverse ratio. The same facilities for the prevention of decay are not available for ships in commission, and if their timbers should have been unseasoned, or have had much of the natural sap left in them, dry-rot must almost necessarily ensue. It may be especially looked for in ships sent to a warm climate immediately after their construction, and exposed to a high temperature, and of its attacking these, many instances have occurred even within the last few years.

The same evils exist to a greater degree in merchant-vessels. Private ship-builders are unable to keep their capital locked up in a large stock of the different classes of timber fit for the different ships they may be called upon to build, and as the purchaser ordinarily requires a speedy execution of his order, the use of unseasoned timber is the necessary consequence. No better arrangements for the prevention of decay seem to be made on board of merchantmen, after they are built, than on board of men-of-war. Lloyd's register of shipping may be said to have an injurious influence on this question. The register is kept by a joint-stock company, and a committee of their body composed of ship-owners, merchants, and underwriters, with a staff of professional surveyors, have laid down a code of rules for the construction of ships as a guide to their classification on survey. By these rules, a ship built of the very best species of timber, thoroughly seasoned, can be classed as a first-class ship for twelve years only; a renewal for eight years may be obtained, but not without much trouble and expense; and further extension again of four years involves another expensive survey. Sufficient inducements are apparently, therefore, not held out for increasing the durability of ships. Many teak-built ships have lasted longer than these assigned limits, and yet no attempts have been made to rival them, thus leading to the belief that Lloyd's rules have had the effect of rendering builders and owners satisfied with existing results. It has been argued that, to season a ship after she is built, by a free circulation of air, will cause shrinkage, and thus injure the good fitting and the strength of the fabric, and that it will strain the fastenings, and admit damp, and thus cause the decay it was intended to obviate. In reply to this it may be urged, that shrinkage could never be produced to this extent on the timbers of a ship by the circulation of air, had they not been in such an unseasoned state as to be totally unfit for use; and that even in such a case, it would be far better to take the chance of less certain mischief, than to leave the ship to inevitable destruction by dry-rot. These remarks show the importance of well-seasoned timber for ship-building, and have been insisted upon here, not from any supposed want of general knowledge of the fact, but to show the importance of applying the means which exist to remedy the evil.

It must be evident that when timber is to be closely jointed to other timber, to form a compact mass, the whole should not be wet with rain, or water-soaked when put in place. The importance of this is recognised by Lloyd's rules allowing one year to be added to the prescribed period of durability of any ship built under a roof. All vessels laid down in royal dockyards have this advantage.

Different qualities in different species of woods.

Different species of timber are possessed of very different qualities, both as regards their durability and their strength. Oaks and other hard close-grained woods, being the most durable, are chiefly used for the frames of ships. The juices of the oak are of an acid nature, and besides the ligneous, which it has in common with other woods, it contains the Gallic acid peculiar to itself. Oak when used in

an unseasoned state is extremely liable to dry-rot, which in some cases has been found to destroy it in the space of a few months. Teak is a very valuable timber for ship-building, but like other woods it varies much in quality according to the soil in which it is grown, and consequently requires great care in its selection. Morning saul, green heart, morra, and iron-bark, are also valuable woods. Like teak they are extremely durable, and are more oily and resinous in their nature than oak. The whole of the foregoing are classed together by Lloyd's committee as superior woods, and are admitted for the construction of ships classed for a durability of twelve years. The general classification of woods by this committee is as follows:—

Mahogany of hard texture, Cuba Sebicu, and pencil cedar, Adriatic, Spanish, and French oak	10 years.
Red cedar, Angelly, and Venatica; other continental white oaks, Spanish chesnut, stringy bark, and blue green..	9 „
North American white oak, and American sweet chesnut	8 „
Larch, hackmatack, tamarac and juniper, pitch pine and English ash..	7 „
Cowdie, American rock elm......................................	6 „
Baltic and American red pine, European and American grey elm, black birch, spruce fir, English beech......	5 „
Hemlock	4 „

There are some slight variations in the durability assigned to these when used for other parts of the ship than the ribs or frames. Elm, which decays very rapidly when alternately wet and dry, is very durable if kept constantly submerged in water. On this account, as well as for its qualities of strength and toughness, it is well adapted for the keels of vessels. Other woods will be mentioned hereafter when the sources of the supply of timber for ship-building are considered.

Means of preserving timber.

The difficulty of obtaining properly seasoned timber whenever it may be wanted, and the great expense attending the early decay of unseasoned timber, have led to various means being proposed for its preservation. Saturating the timber with various chemical compounds, has been the method generally suggested for its accomplishment. In India, Machonochie, by steaming his timber, and then condensing the steam in the tank, and producing a partial vacuum, endeavoured to dissolve and carry off the juices of the timber, and he then submerged it in an oil obtained from the chips and sawdust of teak. Steaming or stoving timber has always been considered advantageous for wood used in a green state. Exposing it to the action of water has been advocated with the same view, and this certainly tends to shorten the time required for weather seasoning thereafter. About 40 years ago the timber used in the royal dockyards was ordered to be submerged in salt water for some time, and then stamped with the word "salt." Pieces of sound timber with this mark are found in men-of-war up to the present day. Mr Kyan patented a process for preserving timber, by saturating it with corrosive sublimate; and Sir W. Burnett, late Medical Director-General of the Navy, patented the use of chloride of zinc, but with neither of these processes is the effect in all cases certain. Creozote appears to preserve timber with greater certainty than any other chemical material yet used. The timber is put into a close tank, the air is abstracted, and the vacuum is kept up for two or three hours by continued pumping, to allow the air to escape from the pores of the wood. The creozote is then introduced, and is forced into the tank, until a pressure of about 150 lb. to a square inch is obtained. This pressure is kept up by continued pumping during successive days for forty-eight hours, or for as long as may be required to make the timber absorb the requisite amount. This process is chiefly used for pine timber. Yellow pine should absorb about 11 lb. to the cubic foot, and Riga pine about 8 lb. The timber is weighed before it is put into the tank, and again after it is taken out, to ascertain the amount absorbed. Should this prove less than the amount required, it is returned to the tank for a repetition of the process.

Steaming and pickling timber. Corrosive sublimate. Chloride of zinc. Creozote.

Creosoted timber has hitherto been chiefly used by civil engineers in land and sea works. The objections to its use in ship-building are its offensive smell and its great inflammability. Its power of protecting timber from natural decay, and of resisting the *toredo novalis*, or any of the other worms to whose ravages ship's timber is subject, if it be not thoroughly covered with copper sheathing, appear to render it peculiarly fit for such a purpose as doubling upon a ship. If found to answer, it might be used in thin boards as a sheathing instead of copper.

Dr Boucherie's process with sulphate of copper.

Another process which is applicable to the preservation of certain descriptions of straight-grained and porous timber, has been patented by Dr Boucherie, a French chemist of note, and been brought forward in this country by a company formed for the maintenance of the permanent way of railways. They have published the following information respecting it. Instead of using great pressure, as before explained, to impregnate the tree, a moderate pressure only is applied to one end of it; the effect is to expel the sap, and fill the tubes or pores of the timber with the preserving liquor. The tubular structure of trees has been long known, and Dr Boucherie's process shows that no connection exists between the tubes laterally. Colouring liquid applied in the form of a letter or word at one end of the tree appears in the same shape at the other. The fluid used by Dr Boucherie is a solution composed of one part of sulphate of copper to one hundred parts of water by weight. The specific gravity of the solution, when of proper strength, at 60° Fahr., is 1·006, or nearly so. A water-tight cap is placed on one end of the tree which is to be saturated, and the solution is introduced within it by a flexible tube. The pressure required not being more than from 15 to 20 lb. on the square inch, it may be obtained in a very simple way, by raising the tank which contains the solution 30 or 40 feet from the ground. When the pressure is applied the sap runs in a stream from the opposite end of the tree; and a ready means exists of discovering when it is exhausted and the whole length of the tree penetrated, by rubbing the end with a piece of prussiate of potash, which will leave a deep brown mark when brought into contact with the copper of the solution. The sap and surplus solution, should any pass through the tree, may be pumped back into the reservoir, the sap being a better solvent of the sulphate of copper than water, if it should happen to be impregnated with lime or other impurities. There are certain kinds of timber which are impenetrable by the solution applied in the manner described. It answers best with trees that are the least costly, as beech, birch, larch, Scotch fir, alder, elm, poplar, &c. Trees felled any time between November and May may be prepared in the latter month. But when they are cut down in May or any month between then and November, they should be prepared within three weeks of the time of felling. It has been found, in the preparation by this system of vast quantities of timber for the French navy and railways, that the time necessary for the operation depends both on the length of the tree and on the description of timber. Trees of 40 feet in length, prepared at Fontainbleau for the French navy, required from eight to ten days to become sufficiently impregnated; whereas for lengths of 9 feet only, the process was accomplished in twenty-four hours. A summary of experiments made in Derby with this process is given in the following table. It will be observed from the facts there stated, that the pores of the poplar are more pervious than those of other woods; and the rapid and large absorption of the fluid by the memel timber shows, that the pores of fir timber, when the natural juices are dried up, still afford a continuous channel for its flow:—

One great advantage attending this method, and which is likely to render its application very general, is the inexpensive nature of the apparatus required.

Weather seasoning.

Seasoning timber, by exposing it for a lengthened period without subjecting it to any other process, has received much attention, and much controversy has arisen upon the best mode of carrying it into effect. It may perhaps be stated as the general opinion, that rough timber may be improved in this country by stacking it off the ground, that it may not be injured by damp. Sided timber, thick stuff, and plank, should always be stowed under sheds, and these must be airy and well ventilated, without partial draught which could affect the ends or any one portion of the timber more than another. Two or three years are required to season these descriptions of timber to a moderate degree only. Mast spars are best protected when submerged under water, and if buried in mud they are still more effectuallly preserved. Boards of mahogany or fir are well seasoned by being stacked on end in the open air without covering, but raised a little from the ground to avoid damp. In the royal yards it was formerly the custom to allow ships to stand in frame for various periods before they were planked, but the necessity of building ships rapidly has of late years precluded the possibility of doing this; and the evil effects have been too apparent. The following tables show the results of weather seasoning, as collected by Mr Fincham, and published in his work on the *Outlines of Ship-Building* :—

Materials used in Ship-Building.

Seasoning timber by desiccation.

Seasoning timber by exposing it to a current of heated air at a higher velocity than is engendered by natural causes, was introduced by Mr Davison. The desiccating process, as he terms it, and as explained by him to the institution of civil engineers in 1853, consists in impelling rapid currents of air through a chamber or chambers containing the wood; spaces being left between the ranges or tiers of timber for the heated air to act uniformly upon all its sides. The moisture, as soon as it is cooled, passes instantly away through an opening in the roof of the chamber, and this appears to be a distinguishing and essential feature in the process. The wood remains in the chamber until by weighing a sample from time to time, the whole aqueous matter had been expelled from its pores. Charring wood in a sand-bath was practised in the beginning of the last century, and apparently with some success; but the heat must have been much greater than that employed by Davison, and the process probably was much more rapid. In carrying out the desiccating system, attention must be paid to the following points:—Different woods and different thicknesses of wood, require different degrees of heat; hard woods and thick logs of wood require a moderate degree of heat, from 90° to 100° Fahr. The softer woods, such as pine, may be safely exposed to 120°, or even to a still higher temperature; and when cut extremely thin and well clamped, 180° or 200° have been found rather to harden the fibre and to increase its strength. Honduras mahogany in boards of one inch in thickness may be exposed with advantage as regards colour, beauty, and strength, to a heat as great as 280° or 300° Fahr. A slab of Honduras mahogany 1½ inch thick, cut fresh from the log, was wholly deprived of its moisture, amounting to 36 per cent. by exposure to the temperature of 300° for fifty consecutive hours. In practice, however, it is found that from 115° to 120° of temperature brings almost every kind of timber in slabs or boards of moderate thickness, safely and steadily towards complete desiccation in a comparatively short space of time. For boards up to 4 inches thick, one week is sufficient for every inch of thickness, thus one week for 1 inch thick, and four weeks for 4 inches thick, but beyond this thickness the proportions require to be increased. For 6 inches thick, seven weeks should be allowed; for 8 inches ten weeks, and so on. These periods are fixed on the supposition, that the rapid forced current of heated air will be kept up only during the day of twelve hours, and that the chamber will then be closed till the following morning, that being the customary mode of working.

English oak requires more than ordinary care when thus prepared. It should never be exposed under any circumstances for any length of time to a higher temperature than 105°; more intense heat has been found to act upon the Gallic acid, or on the fibres in some peculiar way, so as to produce internal fissures. Mr Davison also stated, that still heat like that of an oven had an effect upon wood totally different from that produced by a current of heated air. In the one case the fibre is rendered short, brittle, and weak; in the other, all that is valueless is driven away, and the albumen becomes solidified or coagulated into a hard compact substance, and the fibres gain a great increase of strength and rigidity. Seasoning under ordinary degrees of temperature has a completely different effect on the albumen, which, if not previously dissolved or washed out by any of the processes previously referred to, remains, when dried, in a soft spongy state, ready to become an absorbent of moisture.

It has been found by experience that 100 feet per second is the best velocity for the current of heated air, and with a proportionate area of inlet-pipe, a sufficient quantity should be delivered into the chamber to cause a complete displacement of the air and moisture in three minutes. If a desiccating chamber contains 30,000 cubic feet of air, 10,000 cubic feet ought therefore to be propelled into it per minute, care being at the same time taken that the area of the outlet or outlets for the escape of the moisture exceed the area of the inlet-pipe, and that they be so arranged as to avoid a direct current between them.

The Board of Ordnance adopted this system for gun-stocks in 1840. Previous to its introduction, about 400,000 stocks were undergoing regularly a course of seasoning, each requiring to be turned once or twice every year to avoid the ravages of worms or decay. In a report from Mr Lovell, then her Majesty's inspector of fire-arms, he states respecting some gun-stocks subjected to the process:—"One half of the number were quite fresh cut and green wood, the other moisty, had been about twelve months in store; the total weight before the process, 536 lb. 9 oz., and after sixteen days' exposure to a current of air heated to 110°, or 114° Fahr., that weight was reduced to 413 lb. 14½ oz.; that is to say, 122 lb. 10½ oz. of moisture had been driven off. Some of the stocks had been purposely selected with seen cracks in the butts and other faults, for I expected that those cracks and faults would be exaggerated by the heat of the chamber. But the result was not so; on the contrary, they were closed considerably behind the marks that had been stamped upon the ends of them before they were put in, and the whole number of stocks came out in good condition, and fit for immediate use." He proceeds to say,—"The wood is better seasoned than when dried in the open air; 1*st*, Because the albumen being dried on the pores and in the capillary tubes, renders the fibre stronger and less liable to absorb moisture; 2*d*, The wood is stronger, tougher, and, of course, more capable of withstanding the effects of violent vibration from the laternal adhesion of the fibre being better preserved; 3*d*, It works smoother and more waxy under the chisel, and has less tendency to speel and crumble away, which is generally the great fault of steam-dried timber. I have now worked nearly 30,000 desiccated stocks, none of which had been under the process more than twenty-one days; and my opinion is very decided, that the wood is more thoroughly seasoned, and with much greater certainty, than if it had been merely exposed to the open air in the usual way for three or four years. The desiccating chamber created in the royal manufactory at Enfield continues in full activity. The heat is kept down to a medium degree, between 90° and 100°; and at this temperature it delivers the stocks perfectly seasoned in fourteen to sixteen days, according to the quality of wood, whether of sap or heart; and I propose to subject the whole of the stocks to it in future, whether they have been air-dried previously or not, in order to make sure that the whole shall have been equally seasoned."

Some bearers of Riga pine and American elm, after they had been in use for about six years, and exposed for that length of time to a temperature of 115° or 120° of heat, at which the chamber invariably stood, were examined, and were found to be perfectly sound and in excellent condition; thus proving that the process, even though continued for so long a period, did not injure in the slightest degree the fibre or the strength of the wood.

It is difficult to understand how the timber subjected to this process can be rendered more capable of sustaining a tensile strain, if this be the case, but it is natural that the albumen, when hardened in the pores, should render it more incompressible, and therefore more capable of resisting any strain when the strength depends on this property. For hard woods, to which Dr Boucherie's process is not applicable, desiccation seems to be admirably adapted, Mr Lovell's experience with the walnut-tree gun-stocks appearing conclusive.

The following table is interesting, giving the results of experiments made by Mr Davison:—

Materials used in Ship-Building.

General Results of Desiccation, showing the Percentage lost by four kinds of Timber of different dimensions, seasoned by the Desiccating Process; the Number of Days in which the Seasoning was effected; and the Ratio of Time in which equal degrees of Seasoning were produced, upon duplicate Specimens by the artificial and by the ordinary processes.

The weights were applied at one end of the piece, at a distance of 3 feet from the fulcrums.

The slow progress made in the introduction of this process has doubtless arisen partly from a fear that so speedy a method of drying or seasoning is likely to warp and rend the timber. Though this result does ensue from exposing it to draughts in covered sheds, yet as the evil in this case arises from the partial action of the currents of air on the log or piece of timber, it need not be feared where the temperature and the current are equally diffused, as in the desiccating chamber. The expense of the apparatus is, however, a serious drawback to its introduction, except in works where a very large quantity of timber is used.

Season of felling timber.

The best season for felling timber has been a subject of some discussion; but the evidence that has been collected seems to be in favour of that which is winter-felled. Its specific gravity is less than if summer-felled; and it is natural to suppose that the less amount of sap in the tree will render it more readily and easily seasoned.

The relative value of the various woods must also de-

Materials used in Ship-Building.

pend upon their strength as well as upon their durability. The cohesive strength per square-inch, or power of resisting a tensile strain to tear the particles asunder, varies in different species. Professor Barlow, in his work on the strength and stress of timber, gives it as under for the following kinds of wood:—

Cohesive strength of timber.

Species of Timber.	Cohesive strength per square inch in lbs.
Ash	17,000
Teak	15,000
Fir	12,000
Beech	11,500
Oak	10,000
Pear	9,800
Mahogany	8,000

These being the breaking weights, it will not be safe in practice to expose timber to more than about one-half of them.

Power to resist a crushing force.

Professor Hodgkinson has investigated the powers of different species of timber to resist a direct crushing force, and the results which he obtained show that this power varied greatly according to the state of seasoning. He found that timber, when in a wet and unseasoned state, could be crushed by a force less than one-half of that which would be required to crush it when properly seasoned, the moisture acting as a lubricating medium to allow the particles to slide upon each other more easily.

The following, however, may be taken as the crushing weights of the different species named, in an ordinary state as regards their degree of seasoning:—

Specific Gravity of Specimen.	Species of Timber.	Resistance per square inch in lbs.
·560	Yellow Pine	5375
·540	Cedar	5674
·580	Red deal	5748
·640	Birch	6402
·660	Sycamore	7082
·753	Spanish mahogany	8198
·780	Ash	8683
·700	Dry English oak	9509
·980	Box	9771

No satisfactory rules have yet been promulgated to determine the weights which may be placed with safety upon wooden columns of different diameters and different lengths. It is not unusual in practice to confine the load to 500 lb. per square inch of section on a column of oak, and when required to carry this load per sq. inch, the length is generally limited to fifteen times the diameter. But, however short the column may be, it should never be loaded to a greater degree than one-third of the weights in the foregoing table, and the length should never exceed twenty, or at the utmost twenty-five, times the diameter without a great diminution of the load proposed above.

The strength of similar columns varies inversely as the squares of their lengths. Thus, if the weight which a column of oak of 5 inches diameter and 6 feet long will support with safety be taken at 9800 lb., a column of oak of 5 inches diameter, and 10 feet long, will support only 2450 lb., with an equal degree of safety, because by the proportion mentioned above

$$10^2 : 5^2 :: 9800 : 2450.$$

Transverse strength of timber.

The annexed table of data is given by Professor Barlow, in his work, for determining the weights which the different woods enumerated will respectively carry, when exposed to a transverse strain, and the rules which follow for its practical application are also taken from the same authority:—

Teak	2462	Elm	1013
English Oak	1672	Pitch Pine	1632
Canadian, ditto	1766	Red Pine	1341
Dantzic, ditto	1457	New England Fir	1102
Adriatic, ditto	1383	Riga Fir	1108
Ash	2026	Mar Forest Fir	1262
Beech	1556	Larch	1127

To find the ultimate strength of any rectangular piece of timber fixed at one end and loaded at the other:—

Rule.—Multiply the value given in the table of data by the breadth and square of the depth, both in inches, and divide the product by the length, also in inches; the quotient will be the breaking weights in pounds.

Example 1.—What weights will a beam of English oak sustain before it breaks, when the breadth is 8 inches, the depth 12 inches, and the length 10 feet from the point of support?

The relative strength of English oak, as given in the table, is 1672.

$$\text{Then } \frac{1672 \times 8 \times 12^2}{120} = 16{,}051 \text{ lb., or } 7{\cdot}255 \text{ tons.}$$

Example 2.—What weight will a beam of larch sustain before it breaks, when the breadth is 4 inches, the depth 6 inches, and the length 5 feet from the point of support? Answer—2704 lb.

To find the ultimate transverse strength of any rectangular beam, when supported at both ends and loaded in the centre:—

Rule.—Multiply the value given in the table of data by four times the breadth and square of the depth in inches, and divide that product by the length, also in inches, for the weight.

Example 1.—What weight will be necessary to break a beam of teak, the breadth being 10 inches, the depth 14 inches, supported at each end, and the distance between the faces of the supports being 20 feet, the beam being loaded in the middle?

For teak, the value given in the table is 2462.

$$\text{Then } \frac{2462 \times 4 \times 10 \times 14^2}{240} = 80{,}425 \text{ lb., or } 35{\cdot}904 \text{ tons.}$$

Example 2.—What weight will a beam of English oak carry before it breaks, the breadth being 8, the depth 12 inches; the beam being loaded in the middle, and supported at each end, and the distance between the faces of the supports being 15 feet? Answer—42,803 lb., or 19·153 tons.

If the dimensions of a beam be required so as to support a given weight, the following rule must be used:—

Rule.—Multiply the weight in pounds by the length in inches; and this product, divided by the tabular value, will give the product of four times the breadth and square of the depth; then the breadth being known, we can find the depth; or the depth being known, we can find the breadth.

Example 1.—What must be the dimensions of a beam of English oak to carry a weight of 5 tons in the middle, where the distance between the supports is 20 feet?

The tabular value for English oak is 1672, $\frac{11200 \times 240}{1672} = 1607$, which is the square of the depth multiplied by four times the breadth.

Let the breadth be 6 inches; then $6 \times 4 = 24$, or four times the breadth.

$$\text{Then } \frac{1607}{24} = 66.96 = \text{the square of the depth,}$$

and $\sqrt{66{\cdot}96} = 8{\cdot}18$ inches, or $8\frac{1}{8}$th inches nearly.

Or, if we take the depth at 8 inches, then

$$8^2 = 64 \text{ and } \frac{1607}{64} = 25{\cdot}1,$$

Materials used in Ship-Building.

Materials used in Ship-Building.

and $\frac{25\cdot 1}{4} = 6\cdot 27$, or a little more than $6\frac{1}{4}$th inches = the breadth.

Example 2.—What must be the dimensions of a beam of red pine to carry a weight of 15 tons in the middle, when the distance between the supports is 30 feet? Answer—10 inches in breadth by 15 inches deep nearly.

If a beam be supported at both ends, and the load be equally distributed over its length, it will carry twice the weight; that is, the result obtained by the foregoing rule must be doubled.

If the beam be firmly fixed at both ends, so as to prevent the ends from rising, when the weight is applied in the middle, the result will be increased by its half; that is, a weight of 10 tons may be increased to 15 tons.

If the beam be fixed at both ends and loaded uniformly throughout its length, the result must be multiplied by 3; that is, a beam which will carry 10 tons in the middle when it is laid loosely upon its supports, will carry 30 tons when fixed at both ends, and the load distributed uniformly over its length.

It must always be remembered, in applying these rules to practice, that the weights found by them are the breaking weights. The proportion of the breaking weight with which it is considered safe to load a beam in actual use varies according to the nature of the material. In the case of cast-iron, which breaks without giving any warning, it is not considered safe to place more than one-third of the breaking weight upon it. In wrought iron and timber, which both show symptoms of being overstrained before they break, by becoming crippled, or by an amount of flexure so great as to be very observable to the eye, the load in practice may be one-half of the breaking weight, as found by the rules.

Experiments on the strength of materials are always valuable to practical men, as adding to the store of knowledge, and acting as a check on any rules which may be in use. A series of experiments on timber were made by Colonel Fowke, of the Royal Engineers, at Paris, during the universal exhibition held there in 1855, and the results were published at great length in the report upon that exhibition.

Mr Fincham made some experiments, with great care, on the transverse strength of timber, and the following table, showing the results, is extracted from his work on ship-building:—

A Table of a Series of Experiments on the Strength of the undermentioned species of Timber. In each case the piece was three inches square and four feet long between the supports, and the weights were placed in the middle.

Species of Timber and No. of Experiments.	Specific Gravity.	Weight at which the piece broke.
		Cwts.
English oak, the mean of 8 experiments	·791	32·973
Italian oak, the mean of 4 experiments	1·077	38·792
Dantzic oak, the mean of 4 experiments	·704	39·732
African oak, the mean of 4 experiments	1·021	59·897
Malabar teak, the mean of 4 experiments	·724	43·723
Moulmein teak, the mean of 4 experiments	·909	34·292
Riga fir, the mean of 4 experiments	·576	35·558
Dantzic fir, the mean of 4 experiments	·708	36·718
Italian larch, the mean of 4 experiments	·645	40·047
Scotch larch, the mean of 4 experiments	·561	27·750
Hackmatack larch, the mean of 4 experiments	·708	37·886
Cowdie, the mean of 4 experiments	·614	33·317
Bermuda cedar	·932	36·776
Cuba cedar, the mean of 4 experiments	·524	24·348
Van Dieman's Land cedar	·616	18·303
Mahogany, the mean of 4 experiments	·636	30·093
New South Wales mahogany, the mean of 4 experiments	1·382	36·777

Rigidity of timber.

Rigidity, or the opposite of elasticity, is the power of resisting deflection or bending, when a weight is placed upon a beam, or when a side pressure is brought to bear against it. This power is increased in a much more rapid ratio than the power to sustain loads without fracture; thus, in order that a beam may bear 10 tons with the same degree of deflection as one bearing 5 tons, much less increase of dimensions will be required than will be necessary for a beam whose breaking weight is to be 10 tons, in comparison with one whose breaking weight is 5 tons. The possession of rigidity in a lateral direction is necessary to every beam to a certain extent, to prevent its bending side-wise and becoming crippled, and hence beams must not be too much reduced in their breadth relatively to their depth. In practice, the proportions of 2 for the breadth to 3 for the depth, and also of 3 for the breadth to 5 for the depth, are very common; but in joists of floors, and in other situations, where side props, or supports to prevent flexure, can be introduced, the depth is often made in a greater proportion, with the advantage of a saving of material, to carry the same weight.

Supply of timber.

The supply of timber for ship-building purposes is a subject that has at various periods attracted much attention, both as regards the species grown in this country and those which are imported from abroad.

Some valuable remarks on foreign woods were lately made by Mr Leonard Wray, in a paper read before the Society of Arts, and published in their journal of 6th May 1859. He called attention to the fact, that before forests of the finest timber can be brought into beneficial use, a population is required to fell and trim the trees, as well as a good shipping port, and the cheapest possible means of bringing the timber from its native forests to the port of shipment. Honduras has long had its organised bands of wood-cutters, and has long been one of the most important timber-exporting countries. It now exports about 25,000 tons of mahogany and 6000 tons of logwood annually, and the woodsmen in pursuit of these two staple products continually pass and repass other species of the finest quality of timber in the world. Amongst many other fine trees found there, Mr Wray specially enumerated the following:—The green heart, the live oak (Bignonia), and other oaks; the mahoc, the bullet-tree, the Neesberry bullet-tree, the iron-wood, the locust, used for ships' planking and treenails; the dogwood, the red pine, the pitch pine (much superior to that of Carolina and the other southern states of America), the cedar *(Cedrela odorata)*, a light and durable wood, not liable to dry-rot, nor subject to the attack of insects, and of which the trunk is 70 or 80 feet long, with a diameter of from 4 to 7 feet.

The morra is described by Mr Wray as a most valuable timber, the trees often attaining a height of from 100 to 150 feet, the lowest branches being 60 feet from the ground. The wood is extremely tough, close, and cross-grained, so that it is difficult to split, and not liable to splinter, which renders it particularly adapted for ship-building, more especially in the royal navy. The trunk makes admirable keels, timbers, and beams; and the branches having a natural crookedness of growth, are unsurpassed as knees.

Sir R. Schomburgk, referring to this tree, states that it grows abundantly in Guiana, on the banks of the river Berima, which is navigable for vessels drawing 12 feet of water, so that they might load close to the spot where the trees are cut down.

Mr Wray also mentions many other fine timber trees as the growth of Guiana, and Assam, Tenassarim, and the provinces and settlements in the neighbourhood of the Straits of Malacca. He states that a quantity of teak has for many years been exported from Moulmein, and other parts along the coast, but that the field which this healthy and most pleasant country still presents is so inexhaustible

Materials used in Ship-Building.

that he considers it to stand unrivalled as a timber-producing country. Hitherto teak alone has been exported, but there are others which are considered quite equal, and even superior to it. He gives the following list of some of the best timber woods, which will serve to give an idea of the capabilities of these neglected provinces:—

Anan.—One of the hardest and most compact woods known.
Ahnaun.—Strong and very durable; used in ship-building.
Keoun-lac (Rottlera).—Excellent for rudders.
Kat-wat-na (Cedrela).—Large timber, 40 to 70 feet long; used for ship-building.
Ka-nyeng-kyaung-khyay.—For ship-builders; contains an aromatic oil, and is not attacked by insects.
Kyess-yo.—Similar to teak.
Kud-doot-alaiu.—A large tree; used in ship-building.
Kunnazoo.—A very large tree; very hard and durable timber.
May-Mayka.—Used in ship-building.
May-raug.—Said to be very durable.
May-tobek.—Used for the bottoms of ships, considered preferable to teak.
Mayam.—An indestructible, strong, heavy, dark-red wood.
Podauk.—A beautiful, compact, and hard wood, sometimes called rosewood.
Pengadoh.—Strong and durable.
Pien-mahne.—Yields very strong knee-timber.
Pyau-ga-deau.—Hard, dense, and durable; called iron-wood.
Soondra.—A very tough, elastic wood; said to be the strongest of all the Indian woods.
Thab-bau.—Fine solid timber, sometimes 70 feet long; used for boats.
Thau-kya.—A species of wood similar to Saul.
Tha-nat.—A kind of grey teak.
Tha-nat.—More resembling Saul.
Thau-That.—A capital wood, like Saul.
Theet-ya-hau.—A species of teak; close grained.
Theug-gau (Hopea odorata).—An enormous tree of the Saul tribe; yields a strong, compact, and excellent timber, considered superior to teak; also a quantity of good dammer or resin. Insects never attack this wood, nor is it liable to rot.
Tirbbac (Quercus Amherstiana).—An oak; large tree; used in boat-building.
Thounsauga.—A large tree; used in boat-building.
Thingau-kyauss.—Close grained, strong, heavy wood; used in ship-building.
Thubbae (Mimusops).—Used in ship-building.
Thubbor (Uvaria).—A large tree; used in boat-building.
Toung-byeng.—A kind of red Saul.
Thym-bro.—A good, strong, durable wood; used in boat-building.

Of the Malacca woods Mr Wray gives a long list, and of these he describes the following from his own experience while resident in the straits:—

Murbouw.—Very strong, hard, and heavy; used in shipping; not attacked by insects; will last 100 years.
Binlaugoor.—Valuable wood for ship-building, especially for planks, mast, spars, &c. It grows in great abundance, especially near Singapore, and is largely exported to Mauritius, California, &c.
Vamerlaut.—Hard, tough, and very durable.
Giham.—A pale yellow wood, close grained, hard, elastic, very durable, and generally used in boat-building.
Tampauce.—Used for house-building; hard, and exceedingly durable.
Tamboosu.—House beams; considered very durable.
Galam, *Tikoos* }—Hard, tough, elastic; used in boats.
Marautee.—Very large; light resinous wood, much used for planking, and in building boats.

Australia is the next country to which he directed attention; and though distant, it may yet become an important timber-exporting country, the timber being brought here as a home freight in return for our large exports. The trees of this country which are mentioned are the iron-bark, the tuart, the jarrah blue-gum, and morrell.

The tuart is especially mentioned as adapted for ship-building, as it is most difficult to split, and not liable to splinter.

The jarrah, whose stems average 65 feet long, nearly parallel, and without a branch or knot, is also a most important tree of this colony. It is not attacked by insects of any kind, nor has it any tendency to dry-rot.

There are forests of this wood, almost unmixed with other trees, in Western Australia, of more than 4 miles in depth, and which are known to extend for a length of 150 miles. Planks may be obtained from it 10 feet wide if desired. It is not only valuable as a ship-building timber, but also for furniture, being found of various shades of colour, and of almost every variety of grain.

A ship may therefore be loaded very advantageously with this timber after proper sawing-machinery has been erected in the country, as it may be converted into scantling and other pieces for furniture, which may be stowed along with the balk timber of any size that may be desired.

Some very fine specimens of pine have likewise been imported lately from Vancouver's Island, of immense size, of great strength, and very durable.

Specimens of foreign woods may be found in the collections at Kew; at the Kensington Museum; East India House; Somerset House, Admiralty branch; and at the Crystal Palace.

Since the publication of this paper, containing so much valuable information, and so liberally contributed by Mr Wray to the *Transactions of the Society of Arts*, and from which the foregoing extracts have been so copiously taken, contracts have been made by the government for green-heart Tuart and Jarrah timber. It is to be hoped that this is a prelude to timber from our own colonies being hereafter used in the royal dockyards in larger quantities.

The importance of ship-building timber for the merchant service is undoubtedly decreasing, on account of the increasing use of iron; and it therefore behoves the government to make its own arrangements to originate and foster this trade in those districts pointed out by Mr Wray.

Though insignificant in comparison with these magnificent trees of foreign growth, the increasing quantity of larch now grown in this country deserves attention.

The larch (*Pinus Larix*) now so much grown in England as well as in Scotland, is frequently called Scotch fir, thus being mistaken for the "Scotch fir" as so called in Scotland (*Pinus sylvestris*), which has a dark-coloured foliage. The latter is considered superior for the purposes of architecture, but larch is better adapted for ship-building purposes whenever its size is sufficient. Like most other woods, it varies extremely, according to the soil on which it is grown, and care must therefore be taken in its selection and use. It stands exposure to wet and dry better than most timber, and is hence much used for pit-props in coal mines. The late Duke of Atholl induced the government to build a vessel of larch from his forest. She was called the Atholl; and though her durability has been very great, no further attention appears to have been as yet paid to the subject by the authorities.

Weight of timber.

A knowledge of the weight of the different species of timber is necessary to the naval architect, to enable him to compute or estimate the weight of the hull of the vessel which he is designing or constructing. Mr Edye, the late assistant-surveyor of Somerset House, published an elaborate work containing tables of the weights and the displacements of the different classes of men-of-war of his day, but now rendered comparatively valueless by the introduction of steam-vessels and the great changes in the proportion of ships. The following table, containing the weight of a cubic foot of timber in a green and seasoned state, is extracted from this work; and if the weights of the different timbers be compared with their strengths as previously given, it will be seen that the heavier timbers may be used without increasing the weight of the vessel, as their scantling may be reduced, and the same strength be retained, and with advantage, also, as to durability:—

Materials used in Ship-Building.

Name of Timbers.	Green.		Seasoned.	
	lb.	oz.	lb.	oz.
English oak	71	10	43	8
Dantzic oak	49	14	36	0
African teak	63	12	60	10
Indian teak, green or seasoned, about the same...				
Malabar*	...		52	15
Rangoon*	...		26	4
Indian mast peon	48	3	36	0
Cedar	32	0	28	4
Larch	45	0	34	4
Riga fir	48	12	35	8
New England fir	44	12	30	11
Elm	66	8	37	5
Beech	60	0	53	6
Ash	58	3	50	0

* Malabar teak is the heaviest, and Rangoon the lightest of all the Indian teaks imported.

Materials in combination with timber.

Special care is required in the selection of materials to be used in combination with timber, in order that no chemical or other action, which may tend to premature decay, may take place between them and the timber. Great care is required in the use of iron for fastenings on account of the great affinity which exists between this metal and oxygen. The oxidation of the iron not only destroys the fastening itself, but has an injurious effect upon the timber surrounding it. If the nature of the wood be such that a supply of oxygen from the atmosphere can be kept up through its pores, the oxidation and destruction of the iron will be very rapid. The use of iron in combination with oak is particularly objectionable on account of the acid nature of this wood, and the quantity of oxygen which it contains. In oily and resinous woods the surface of the bolt, when driven, receives a coating of this matter, and is thus rendered less liable to oxidation. Such woods are also more impervious to the passage of a continued supply of oxygen. Iron fastenings, under copper sheathing, are also liable to be destroyed by the galvanic action which takes place between these metals. Many attempts have been made to prevent this action by driving the bolt so far into the wood that a cement of some kind could be put over the head of it, so as to break the connection between the metals, but no important results of any system of this kind are as yet known to have obtained.

Copper is therefore used largely for the fastenings of ships. This metal is liable to a very slight oxidation only upon its surface, and when this has taken place, all further oxidation ceases, and the metal is not destroyed, as is the case with iron. Copper, however, is not possessed of the same strength as iron, and is soft and ductile in comparison with it. It is therefore far from being so good a fastening, especially when driven through iron-knees and iron-riders. It is liable to be bent and crushed, or crippled at the neck, by the iron through which it has passed, if the ship be severely strained and work in any degree.

Some valuable experiments were made on the tensile strength of bolts of dockyard copper, Grenfell's copper, and Muntz's yellow metal, by Mr Jn. Kingston, of Woolwich dockyard.

The results are shown in the following table:—

Description of bolt.	Tensile strength per square inch.
Dockyard copper, average of 12 experiments	49,490 lb., or 23 tons very nearly.
Grenfell's copper, average of 11 experiments	46,592 lb., or 20¾ tons nearly.
Muntz's yellow metal, average of 11 experiments	49,945 lb., or 22¼ tons nearly.

Copper, from its ductile nature, is quite unfit to be used for any purpose where a cross-strain has to be resisted.

A late invention, by which a coating of copper is put upon iron, in the same manner that iron-plates are coated with tin, promises to be very valuable. Fastenings of this kind will then combine all the good qualities of both metals, and will tend materially to strengthen the general fabric of the ship.

Treenails of timber, equal in quality to that through which they are to be driven, make excellent fastenings, but their strength and their power of holding are not such that they can be used to the entire exclusion of metal fastenings.

Sheathing.

The materials used for the sheathing of ships to protect them from fouling, and from the attacks of the *teredo navalis*, and other destructive worms, are chiefly copper and Muntz's metal. These metals are kept clean by the sea-water acting slightly upon them as a solvent, or by oxidation; and a gradual waste is therefore taking place continuously from their surface, thus preventing the adherence of any animal or vegetable matter. With a view to obviate this gradual wearing away, Sir H. Davy proposed to induce a galvanic action upon the sheathing by attaching protectors of iron on its surface. He succeeded to some extent; but in proportion as the iron was eaten away and the copper preserved, it became foul with sea-weed and shell-fish, so that his proposal was abandoned.

Iron for Ship-building.

The use of iron having now become common in the construction of ships instead of timber, a thorough knowledge of its properties is thus rendered necessary to the naval architect. The properties of wrought or malleable iron, as a material for the construction of the component parts of ships, will first be considered in a general point of view.

Cohesive strength.

The strength of rolled iron varies with its quality; the results given will be those due to an average quality, such as ought to be used in ship-building. The cohesive strength of bar-iron, or its power to resist a tensile strain, may be safely taken at 25 tons, or 56,000 lb. per square inch of section. Messrs Robert Napier and Sons of Glasgow have made some valuable experiments on the cohesive strength of wrought-iron, and steel bars and plates, which have been published in the *Transactions of the Institution of Engineers in Scotland*, vol. ii., 1859, and the results, along with others, by Mr Fairbairn of Manchester, on iron-plates, are given here by their kind permission.

Bar-iron.

Table of the average Strength of Steel-bars, as found by Messrs Napier and Sons.

Steel-bars.	Strength per sq. inch of section.
Cast-steel for rivets	106,950 lb.
Homogeneous metal for rivets	90,647 „
Puddled steel-forged bars	71,486 „
„ „ rolled bars	70,166 „

The average cohesive strength of rolled bars of Yorkshire iron was found by Messrs Napier to be 61,505 lb. per square-inch, this being the mean of twenty experiments on bars varying from $\frac{11}{16}$th inch diameter, up to 1 inch square. And the average strength of bars manufactured by nine different makers in different parts of the country, and purchased promiscuously in the market, was 59,276 lb.; this being the mean of 110 experiments on bars varying from $\frac{11}{16}$th up to $1\frac{1}{8}$th inch diameter, and it is most satisfactory to find that the experiments showed a remarkable uniformity of results.

Experiments on plates by Mr Fairbairn.

Mr Fairbairn of Manchester directed his attention, at a very early date, to the subject of iron for ship-building, commencing his operations by the construction of various small vessels for canal navigation. In 1830 and 1831 he built three iron steam-vessels for the Forth and Clyde Canal Company, and to be employed as coasting traders to Grangemouth. These vessels made the voyage from Liverpool to Glasgow, and showed such symptoms of strength as to induce Mr Fairbairn to enter more largely into the business.

Materials used in Ship-Building.

Within the next four years he constructed a vessel for the Lake of Zurich, and two river-steamers of about 170 tons for the navigation of the Humber; and in 1836 he commenced the building of iron-ships at Millwall, on the Thames, in company with others. With a view to the introduction of correct principles into what was then a new line of manufacture, he made some valuable experiments at Manchester in 1838, to test the strength of iron-plates and of riveted joints. The results were communicated to the Philosophical Society of that town, and have since been republished by him.[1] The results which he obtained were as follow:—

Cohesive strength of plates.

Species of Iron.	Mean breaking Weight in the Direction of the Fibre, in tons per sq. inch.	Mean breaking Weight across the Fibre, in tons per sq. inch.
Yorkshire plates....................	25·770	27·490
„ „	22·760	26·037
Mean......................	24·205	26·763
Derbyshire plates....................	21·680	18·650
Shropshire plates....................	22·826	22·000
Staffordshire plates....................	19·563	21·010
Mean......................	21·350	20·553

The plates experimented upon were as nearly $\frac{1}{4}$ inch thick as could be obtained; due allowance being made, in calculating the results, for any excess or deficiency in thickness in the different specimens.

The section through AB was 2 inches wide. The plate having been made narrower there to ensure its breaking at that part. Plates were riveted on each side of the ends to stiffen them. The holes O (fig. 14) were bored through the

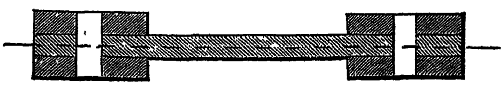

Fig. 13.

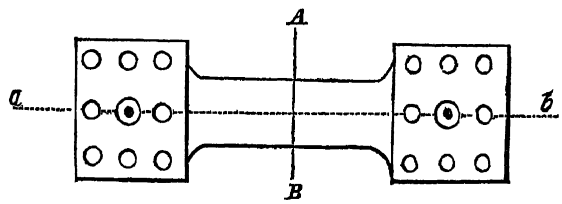

Fig. 14.

ends at right angles to the plates, with their centres in a direct line along the centre line of the part AB; and the apparatus for tearing the plates asunder was attached by bolts passing through these holes.

Iron-plates are supposed to be fibrous lengthwise, or in the direction in which they are rolled; but their cohesive strength ought to be nearly equal, whether the strain be applied with the fibres or across it. This uniformity of strength is attained by the shingles, or piles from which the plates are rolled, being composed of layers of bars carefully selected and laid at right angles to each other. When plates are very inferior in this respect, they may be supposed to have been manufactured from masses or blooms made up of irons and ores of different qualities, and these not sufficiently worked to amalgamate them properly. In testing iron-plates, it is therefore important to test their strength in both directions.

Messrs Napier's experiments.

The very extensive series of experiments on the strength of iron-plates by Messrs Napier have fully corroborated the results previously obtained by Mr Fairbairn. The strengths per square inch of sections were as follow:—

Materials used in Ship-Building.

Yorkshire Plates.

Lengthwise..55.433 lb.
Crosswise..50,462 „
Mean strength..52,947 „

This result being obtained from 45 experiments upon plates varying in thickness from $\frac{1}{4}$ inch up to $\frac{3}{4}$ inch.

Ordinary best, and best best boiler-plates, as manufactured by ten different makers in different parts of the country, and purchased promiscuously in the market—

Lengthwise......................................50,242 lb.
Crosswise......................................45,986 „
Mean strength......................................48,114 „

This result being obtained from ninety-three experiments upon plates varying in thickness from $\frac{1}{4}$-inch up to $\frac{3}{4}$-inch.

Glasgow Ship Plates.

Lengthwise......................................47,773 lb.
Crosswise......................................44,355 „
Mean strength......................................46,064 „

This result being obtained from twelve experiments on plates, varying in thickness from $\frac{5}{16}$-inch up to $\frac{3}{4}$-inch.

Messrs Napier made some experiments upon steel-plates also, with a view to test their value for the construction of light boats for river navigation, or for any portion of iron-ships generally. The results were as follow:—

The Mersey Company's Steel-plates, for Ships.

Per sq. in. of section.
Lengthwise......................................101,450 lb.
Crosswise...................................... 84,968 „
Mean strength...................................... 93,209 „

Steel-plates for Ships—Puddled Steel—"Mild"—by the same makers.

Lengthwise ....71,532 lb. per sq. in.
Crosswise..........................not recorded.

Blochairn Boiler-plates—Puddled Steel.

Per sq. in. of section.
Lengthwise......................................96,320 lb.
Crosswise......................................73,699 „
Mean strength......................................85,010 „

Homogeneous Metal.

Per sq. in. of section.
Lengthwise......................................96,280 lb.
Crosswise......................................97,150 „
Mean strength......................................96,715 „

Same Metal—Second Quality.

Per sq. in. of section.
Lengthwise......................................72,408 lb.
Crosswise......................................73,580 „
Mean strength......................................72,994 „

The portions of the plates tested by Messrs Napier and Sons were made of a similar form to those tested by Mr Fairbairn. As the result of these experiments, it may fairly be assumed, that iron-plates of good average quality should stand a strain of 56,000 lb., or 21 tons, as their breaking weight per square inch of section.

The results from the Yorkshire plates have been kept separate, because their quality and their price are such as to preclude their general use in ship-building. In boiler-making they are only used for furnaces, and those parts which require especial care.

The strength of rivets and of riveted joints, to connect plates in various ways, was also made the subject of experiment by Mr Fairbairn in 1838; and as no subsequent experiments appear to have thrown any further light upon the subject in its bearing upon ship-building, the results obtained at that time will be given.

The experiments were conducted in the same manner as those to test the strength of plates.

[1] *Useful Information for Engineers,* London, Longman & Co., 1856.

Materials used in Ship-Building.

In lap-joints with a single line of rivets, the edges are made to lap over each other, thus—

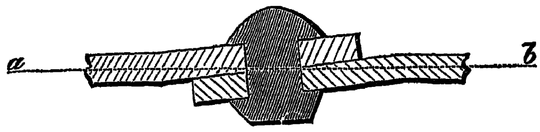

Fig. 15.

When the strain is applied to a joint of this kind, the edges of the plates turn up, and the plates themselves bend till they take the direct line of the strain, as indicated by the dotted line, *a b*.

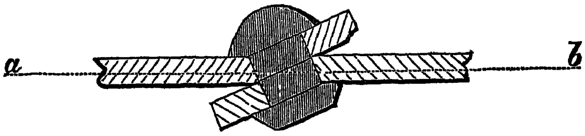

Fig. 16.

Plates may also be united by bringing their edges together to make a flush or butt-joint, putting an extra piece of plate behind the joint to which both plates are riveted by single lines of rivets, thus—

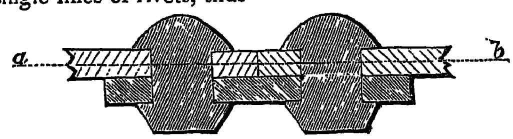

Fig. 17.

This joint also gives way by the plates bending and taking the line of strain; and no material difference of strength was found between this and the preceding joint.

Tredgold has shown that when the line of strain is not in the axis or centre of the material, the strength decreases with the divergence in a much more rapid ratio than the direct distance of the divergence. It is therefore evident that this evil is greatest in thick plates, and that the strength of thick plates will not be proportioned to that of thin plates, though the sections of each through the rivet-holes may bear the same relative proportion to the sections through the solid plates.[1]

Double-riveted lap-joints are those in which a second line of rivets is introduced. The edges are overlapped as in single riveting, but to a greater breadth, thus—

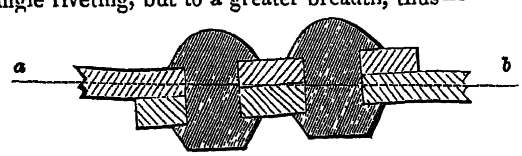

Fig. 18.

The line of rivets nearest the edge keeps it from rising.

In this joint the strength is much increased, but the plates bend as before, and take the line of tension when a direct tensile strain is brought upon them.

The edges may also be brought together flush, with a broader piece of plate behind the joints, and a double line of rivets, thus—

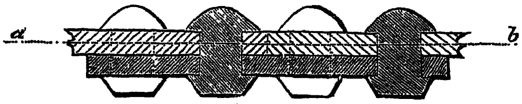

Fig. 19.

In this joint, also, the plates bend before they give way, and the strength is similar to that of the preceding double-riveted joint.

The relative strength of these joints, in comparison with the strength of the body of the plate, was found to be as follow:—

Strength of the plate	100
Double-riveted joints	70
Single do. do.	56

Materials used in Ship-Building.

Countersinking the rivets, or making the heads flush on the outside, was not found to make any appreciable difference of strength.

The strongest mode of jointing plates is by bringing a lapping piece of plate upon each side, and passing the rivets on each side of the joint through the three thicknesses. In the experiments of 1838 upon this joint, double-riveting only was tested; but in subsequent experiments suggested by Mr Fairbairn, and carried out in the construction of the Menai tubular bridge, four lines of rivets were used, thus—

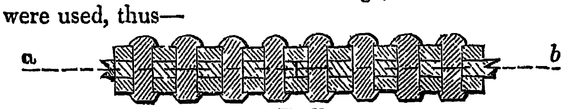

Fig. 20.

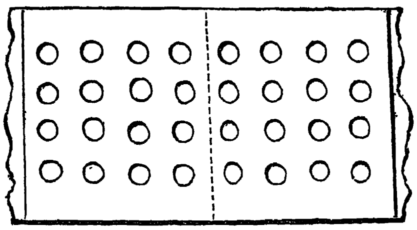

Fig. 21.

In this joint a tensile strain is directly in the line of the joint, and the material is therefore in the best position for exerting its full strength.

This joint, however, is not applicable to the sheathing of ships, on account of the necessity of keeping the exterior surface flush and smooth. But no other joint should be used in uniting plates in the construction of beams, or other parts, in the interior of a ship.

A complete system of two thicknesses of plates, for the whole surface of the plating, has been occasionally used, so as to break joint where a large flat surface of great strength has been desired, with a lapping piece on each joint, thus—

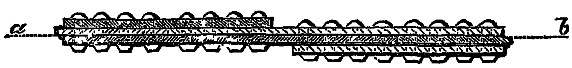

Fig. 22.

The evil, however, which results from the line of the strain not being in the centre line of the joint affects this system of double plating, and the full strength attainable from the material is not secured. The only advantage gained is, that in the event of one plate being defective, a partial remedy will thus be supplied by the second plate.

By the same series of experiments in 1838, the diameter and distance apart of the rivets, and the proper amount of lap for plates, up to ¾ inch thick, were very accurately ascertained, and the following table was formed:—

Table exhibiting the strongest forms and best proportions of Riveted Joints, as deduced from Experiments and actual Practice.

Thickness of Plates in inches.	Diameter of Rivets in inches.	Length of Rivets from the Head in inches.	Distance of Rivets from Centre to Centre in inches.	Quantity of lap in Single Joints in inches.	Quantity of lap in Double-Riveted Joints in inches.
·19 = $\frac{3}{16}$	·38 } 2	·88 } 4·5	1·25 } 6	1·25 } 6	For the double-riveted joint add ⅔ds of the depth of the single lap.
·25 = $\frac{4}{16}$	·50	1·13	1·50	1·50	
·31 = $\frac{5}{16}$	·63	1·38	1·63 } 5	1·88	
·38 = $\frac{6}{16}$	·75	1 63	1·75	2·00 5·5	
·50 = $\frac{8}{16}$	·81 } 1·5	2·25	2·00 } 4	2·25 } 4·5	
·63 = $\frac{10}{16}$	·94	2 75	2·50	2·75	
·75 = $\frac{12}{16}$	1·13	3·25	3 00	3·25	

[1] This subject has also been ably investigated in a pamphlet and report on W. Bertram's patent welding process, by Mr Renton, C.E.

Materials used in Ship-Building.

The figures 2, 1·5, 4·5, 6, 5, &c., in the preceding table, are multipliers for the diameter, length, and distance of rivets, also for the quantity of lap allowed for the single and double joints. These multipliers may be considered as proportionals of the thicknesses of plates to the diameter, length, distance of rivets, &c. For example, suppose we take $\frac{3}{8}$ plates, and require the proportionate parts of the strongest form of joint, it will be

$·375 \times 2 = ·750$ diameter of rivet, $\frac{3}{4}$ inch.
$·375 \times 4\frac{1}{2} = 1·688$ length of rivets, $1\frac{5}{8}$ inch.
$·375 \times 5 = 1·875$ distance between rivets, $1\frac{3}{4}$ inches.
$·375 \times 5\frac{1}{2} = 2·063$ quantity of lap, $2\frac{1}{16}$ inches.
$·375 \times 8 = 3·438$ quantity of lap, for double joints, $3\frac{1}{2}$ inch.

In practice plates and rivets of certain thicknesses and diameters only are obtainable in the market, and for these the table would stand thus:—

Thickness of Plates in inches.	Diameter of Rivets in inches.	Length of Rivets from the Heads in inches.	Distance of Rivets from Centre to Centre in inches.	Quantity of lap in Single Joint in inches.	Quantity of lap in Double-Riveted Joints in inches.
$\frac{3}{16}$	$\frac{3}{8}$	$\frac{7}{8}$	$1\frac{1}{4}$	$1\frac{1}{4}$	$2\frac{1}{16}$
$\frac{1}{4}$	$\frac{1}{2}$	$1\frac{1}{8}$	$1\frac{1}{2}$	$1\frac{1}{2}$	$2\frac{1}{2}$
$\frac{5}{16}$	$\frac{5}{8}$	$1\frac{3}{8}$	$1\frac{5}{8}$	$1\frac{7}{8}$	$3\frac{1}{8}$
$\frac{3}{8}$	$\frac{3}{4}$	$1\frac{5}{8}$	$1\frac{3}{4}$	$2\frac{1}{16}$	$3\frac{1}{2}$
$\frac{1}{2}$	$\frac{13}{16}$	$2\frac{1}{4}$	2	$2\frac{1}{4}$	$3\frac{3}{4}$
$\frac{5}{8}$	$\frac{15}{16}$	$2\frac{3}{4}$	$2\frac{1}{2}$	$2\frac{3}{4}$	$4\frac{1}{16}$
$\frac{3}{4}$	$1\frac{1}{8}$	$3\frac{1}{4}$	3	$3\frac{1}{4}$	$5\frac{5}{16}$

By using these proportions, it will be found that the rivets will not be sheared in two by the plates when a strain is brought on them, and that efficient joints will be made for all vessels which require to be steam or water tight. When this is not required, some additional strength may be obtained by enlarging the rivets and increasing the distance between them.

Machine riveting.

In forming the hull of a ship, the riveting is at present entirely performed by manual labour; but in the construction of beams, or any such separate parts, considerable advantage, both as regards strength and economy, will be obtained by riveting them by machine. The rivet by the latter process is more compressed, and thus made to fill the hole; and the operation being completed while the rivet is still hot, its shrinkage in cooling draws the plates together. This adds to the strength of the joint by causing friction, when a strain is applied to pull it asunder. The extent, however, of the advantage so obtained is necessarily very variable, depending on the amount of compression by the machine in forming the head of the rivet, and on the temperature of the rivet when closed, Mr Fairbairn does not attach much importance to it, and as it certainly does not exist to any important extent in hand-riveted work, it is safest to disregard it when any calculations of strength are being made.

Rigidity of plate.

The liability of plate to yield by flexure depends upon its thickness, and upon the amount of lateral support given to it, compared with the area of its surface. To give to different plates an equal capability to resist flexure, the unsupported lengths should vary as the thickness.[1]

Transverse strength of iron.

The transverse strength of iron equally requires the attention of the iron ship-builder. It is necessary to bear constantly in mind, that in supporting a load, or resisting a transverse strain, the upper portion of a beam, which is supported at both ends, is subjected to compression, while the lower portion is in a state of tension. The line between the particles exposed to these opposite forces is called the neutral axis; but its position and direction, whether straight or curved, has not yet been definitely or mathematically determined. If the material of which a beam is composed be better able to resist compression than extension, it is evident that there may be less material in the upper than in the lower portion of the beam. The power to resist fracture is therefore looked upon as mainly concentrated in these portions; and while the duty of the centre portion, called the plate or the web of the beam, has not yet been brought clearly under the rigid laws of mathematics, its chief duty may be said to be to keep the top and bottom flanches separate from each other, and in their relative positions.

Power to resist compression.

The power of iron to resist compression is generally taken at $31\frac{1}{4}$ tons, or 70,000 lb. per square inch.

It is one of the advantages of iron over wood that it can be made of any form, and that we can thus bring the foregoing principles, in as far as we are acquainted with them, into action.

Advantageous forms can be given to iron.

The accompanying sections may be taken as representing the sections of the beams in general use at the present day.

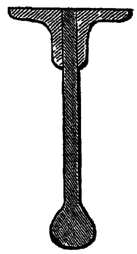

Fig. 23.

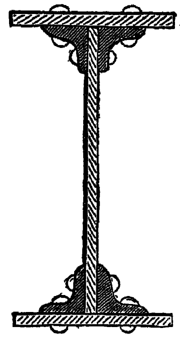

Fig. 24.

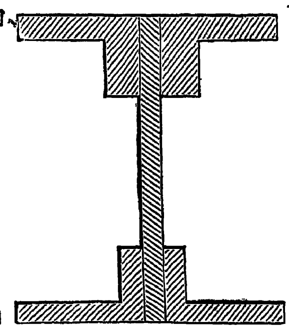

Fig. 25.

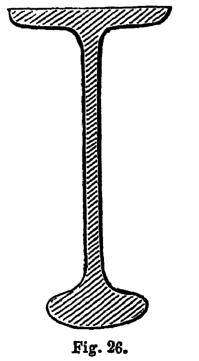

Fig. 26.

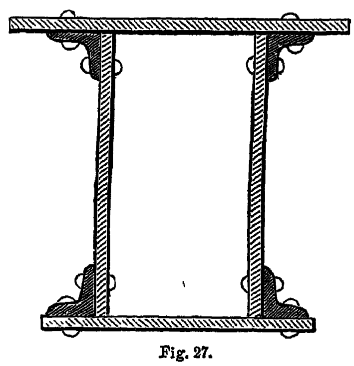

Fig. 27.

The proper proportions of iron-beams, and the consequent rules for their strengths, have been much discussed.

Box-girders were used for the paddle beams of vessels built at Millwall by Messrs Fairbairn and Co. as early as 1840. They are stronger than any of the forms of plate-beams given above; and for long spans on board ship, plate-beams should not be used on account of their want of lateral stiffness, unless they are supported by trimmers or fore and aft carlines.

The ordinary rule for the strength of iron-beams, as given by Mr Fairbairn, is applicable to all the foregoing forms, the number 80 being used as the constant to represent the strength of the box-beam, and 75 that of the plate-beam.

Let W represent the breaking weight in tons, a the area of the bottom flanche, d the depth of the beam, and l the length of the beam, C representing the constant as usual. Then the area of the bottom flanche multiplied by the depth of the beam, and by 80 for a box-beam, and 75 for a plate-beam, and the product divided by the length of the beam (all these dimensions being

[1] See *Proceedings C. E. Inst.*, vol. xv., p. 176; and the subject will be found further investigated, vols. xi., xiv., and xvi.

Materials used in Ship-Building.

taken in inches), will give the breaking-weight in tons—or $W = \frac{adc}{l}$.

It will be observed that the top flanche is not an element in this formula. Its correctness, therefore, is dependent upon the maintenance of certain relative and definite proportions in the parts, and it is not applicable to beams of indefinite forms or proportions. For beams of the ordinary length used in ships, the top and bottom flanches may be made of equal sectional area, and the greater the length of the beam the greater should be the comparative sectional area given to the top flange, to prevent its buckling or bending.

It has been argued that one-half the area of the centre web or plate should be added to the sectional areas of the top and bottom flanches, so as to include its strength as one of the elements of the formula, and a new formula be then deduced, but the rule, as given, is more simple, and may be relied upon.

From the nature of the material it is considered that wrought-iron beams may be loaded up to one-half of their breaking weight, though with cast-iron this limit is not permitted to exceed one-third.

The following are given as examples of the rule:—

(1.) What is the breaking weight of a box-beam 60 feet long, between the supports 18 inches deep, and the area of the section of the bottom flanche being 16 inches?

$$W = \frac{16 \times 18 \times 80}{720} = 32 \text{ tons.}$$

(2.) What is the breaking weight of a plate-beam 30 feet long, between the supports 10 inches deep, and the area of the section of the bottom flanche being 5 inches?

$$W = \frac{5 \times 10 \times 75}{360} = 10{\cdot}41 \text{ tons.}$$

Power of wrought-iron to resist a crushing force.

The crushing force which malleable iron is capable of sustaining has been stated to be 70,000 lb. per square inch, but it could only sustain this great load when the force applied is so truly in the axis of the material, and when the specimen under pressure is so short that no deflection is produced. Wrought-iron, however, is very liable from its nature to give way by bending or buckling when the length bears too great a proportion to the area of the cross-section. This was previously mentioned when the relative sections of the area of the top flanches of beams which are exposed to a crushing force were recommended to be increased.

It has been found by experiment that wrought-iron is crippled, and its power of resistance destroyed by a weight of 30,000 to 40,000 lb. per square inch, whenever the length is such as to permit of its bending. The load, therefore, which it may be considered safe to put upon it in practice may be assumed at 6000 to 8000 lb. per square inch for columns of ordinary proportions. With this load the length of the column should not exceed ten times its diameter, and however short the column may be made, the load should never exceed 10,000 lb. per square inch of section.

The strength of similar columns of wrought-iron, as before stated to be the case with wooden columns, also varies as the squares of their lengths inversely. In all columns it is most important that the pressure should be applied in the line of the axis of the material.

By Hodgkinson's valuable experiments on the subject of columns, it was found that the strength of a column rounded at both ends, in comparison with one whose ends were flat, was as one to three. This result no doubt arose mainly from the strain not being correctly conveyed and kept in the axis of the material. If the strain on a column be in any degree greater on one side than on the other, this side will be unduly compressed, while the other side will be extended, and fracture or crippling will take place with a very small proportion of the load which the column ought otherwise to have sustained.

Dr Young was the first to investigate this subject properly, and his work may still be consulted with advantage by any one who is desirous of following up this inquiry. When treating of the strength of riveted joints, the importance of attending to the line of the strain, when the material was exposed to a tensile force, was dwelt upon; and it is evident, from what has now been said, that this is equally important when it is exposed to a crushing force. In the latter case, if the column be in the least degree curved, the strain increases the deflection, whereas in the former any curvature will be diminished, the tendency being to pull the material into a straight line. Hence, it is of the greatest importance to place columns directly under the weight which they have to support, and by all means to avoid unequal strains on the sides, whether the columns be round or square. With wrought-iron it is also very evident, that by using a hollow column much greater strength is obtained from the same quantity of metal, great stiffness being obtained by the increased dimensions. Hollow wrought-iron tubes, such as those used by engineers in boiler-making, may therefore be used with great advantage. They may be rolled to almost any diameter and length likely to be required in shipbuilding. No experiments appear yet to have been made on the power of such tubes to resist a direct crushing force, but the following experiments were lately made at Portsmouth Dockyard, by Mr Lynn of that yard, to test their power of resistance when used at an angle, as a pair of sheer-legs, to raise screw-propellers on board ships. The tubes were $\frac{1}{2}$ inch thick, 4 inches external diameter, and 12 feet long. They were fitted with wrought-iron ends, the lower ends being prepared to rest on a step on the deck, and the upper ends had a double and single eye to fit into each other, and receive a pin for the shackle to carry the weight. The length was thus increased, from step to eye, to 12 feet 5 inches. At 9 feet spread at the base, one of the tubes which had been annealed in the fire for the purpose of straightening it, as it was slightly curved when received from the maker, deflected $\frac{3}{4}$ inch when the weight reached 26 tons. On removal of the weight it returned $\frac{3}{8}$th inch, leaving a permanent set of $\frac{3}{8}$th inch. At 7 feet spread at the base, the same tube yielded when the weight reached $29\frac{1}{2}$ tons, the other tube remaining uninjured.

Strength of wrought-iron tubes.

Durability of iron.

The durability of iron is entirely dependent upon the state in which its surface is kept. Under ordinary circumstances there is probably no better preservative than good paint; but in the interior of iron-vessels it tends materially to their preservation, if the surface be coated with asphalte, or cement sufficiently thickly to cover the heads of the rivets. In some cases it is even desirable, especially in the sharp run of a ship fore and aft, in the position of the dead-wood in a wooden vessel, to fill up the entire spaces between the frames, and form a flush surface. The exterior also of an iron-vessel is easily maintained in good condition by frequent painting. Below the water-line, where the surface cannot be reached by heeling the ship to a moderate degree, the iron is not apt to corrode. There is no chemical action by sea-water upon malleable iron, and there is not sufficient oxygen present below the surface to induce oxidation. In every instance in which an iron-vessel has been rapidly destroyed, it has been by corrosion on the interior surface. Great injury has in some cases resulted from acids leaking from certain cargoes, such as sugar, and also in parts where the leakage of brine from provision casks has been allowed to lie upon the plates.

For gun-boats or vessels, which it may be desired to lay up or preserve for any lengthened time, iron is peculiarly adapted, as, under such circumstances, the whole of the

Practical Building.

surfaces can always be attended to both externally and internally.

Malleable-iron, when submerged in salt-water, rapidly becomes foul by sea-weed and shell-fish adhering to its surface; but these do not cause decay; they may rather be said to form a coating to protect the iron from decay of any kind as long as it is submerged.

Iron in contact with copper acted on.

The decay of iron externally on ships' bottoms has, however, been observed to take place in the neighbourhood of copper-pipes. This is caused by a galvanic action which takes place between the copper and the iron, tending to the preservation of the former and the destruction of the latter, on the same principle as that proposed to be brought into action by the use of Sir Humphrey Davy's protectors for the preservation of copper sheathing. A layer of zinc at the point of junction, to separate the copper from the iron, will protect the iron, but as the zinc will then be rapidly eaten away, care must be taken that it is not used in such a manner that a leak would ensue in consequence.

Preservation from fouling.

The ready fouling of iron in sea-water is still a great drawback to its use. Many applications for this purpose have been proposed, but none seem yet to have been so thoroughly successful as to require any special mention as deserving of any decided preference.

Weight of iron.

The weight of a cubic foot of wrought-iron is 480 lb. The weight of a square foot of plate $\frac{1}{4}$th inch thick, is therefore 10 lb., and this gives a ready and easily remembered standard for calculating the weight of any surfaces of iron of different thicknesses.

PRACTICAL BUILDING.

There is, perhaps, no structure exposed to a greater variety of strains than a ship, and none in which greater risks of life and property are incurred.

Strains to which a ship is liable.

A consideration of the disturbing forces in action, either to injure or destroy the several combinations embraced in its structure, is therefore most important. And a thorough knowledge of their action is necessary to a practical builder to enable him to guard against them, in whatever form they may present themselves, and to dispose and arrange the materials at his command, accordingly, in the most judicious manner. Some of these forces are always in action whether the ship be at rest or in motion. She may be at rest floating in still water, or she may be cast on shore; and when there she may be resting on her keel as a continuous bearing, with a support from a portion of her side; she may be supported in the middle only, with both ends for a greater or less length of her body left wholly unsupported; or she may be resting on the ends with the middle unsupported: or under any other modification of these circumstances, and under all these the strains will vary in their direction and in their intensity.

If the ship be in motion, the same disturbing forces may still be in action, with others in addition, which are produced by, and belong only to, a state of motion. When a ship is at rest in still water, it has been before explained, that the upward pressure of the water upon its body is equal to the total weight of the ship, but it does not necessarily follow that the weight of every portion of the vessel will be equal to the upward pressure of that portion of the water directly beneath it, and acting upon it; on the contrary, the shape of the body is such that their weights and pressures are very unequal.

If the vessel be supposed to be divided into a number of laminæ of equal thickness, and all perpendicular to the vertical longitudinal section, it is evident that the after laminæ comprised in the overhanging stern above water, and the fore laminæ comprised in the projecting head also above water, cannot be supported by any upward pressure from the fluid, but their weight must be wholly sustained by their connection with the supported parts of the ship. The laminæ towards each extremity immediately contiguous to these can evidently derive only a very small portion of their support from the water, whilst toward the middle of the ship's length a greater proportionate bulk is immersed, and the upward pressure of the water is increased.

At some certain station from the middle of the length in each body, fore and aft, the upward pressure will therefore be equal to the weight of the superincumbent laminæ, and all the laminæ composing that portion of the body between these two stations will be subjected to an excess of pressure above their weight, tending to force them upward; which upward pressure will be the greatest at the laminæ having the greatest transverse area of section. Now, as the total pressure upward is equal to the total weight of the vessel, this excess of upward pressure to which the midship part of the body is subjected, must be equal to the excess of weight over the upward pressure in the parts of the vessel before and abaft those laminæ at which the pressure and weight have been supposed to be in equilibrio.

A ship, when at sea, is subjected to severer strains than when floating at rest, and if cast on shore it may be subjected to still greater strains. Its strength, therefore, as a fabric, should be considered with reference to the severest trial of strength which may be required of it under any circumstances.

A ship floating at rest under the view just taken of the relative displacement of different portions of the body, if the weights on board are not distributed so that the different laminæ may be supported by the upward pressure beneath them as equally as possible, may be supposed to be in the position of a beam supported at two points in its length at some distance from the centre, and with an excess of weight at each extremity.

At sea it would be exposed to the same strain; and if supported on two waves, whose crests were so far apart that they left the centre and ends comparatively unsupported, the degree of this strain would be much increased. The strain would be still more severe if the vessel got aground, and rested on two isolated points situated in the supposed positions in her length.

Under these circumstances, however, the strain would depend upon whether the weights in the middle or in the ends preponderated. The latter is the usual case; and then the whole of the upper portion of the vessel will be subjected to a tensile strain from the tendency of the ends to droop.

The more these two points of support approach each other, or if they come so near each other that the vessel may be looked upon as supported on one wave, or on one point only in the middle of her length, the greater will be the tensile strain on the upper portion, and the crushing strain on the lower portion of the fabric of the ship.

The importance, therefore, of so forming the deck and the upperworks that they may afford an efficient tie is apparent; and it is to be feared that this has been too much neglected, especially in many iron-ships.

If a vessel be weak in this respect, and touch the ground in the middle of her length, the consequences will necessarily be most disastrous, as she will open at perhaps more than one place, and her sides will tear down instantaneously after the tie of the deck and upperworks is gone. These results appear to accord with the accounts given of the manner in which several iron-vessels have broken up on their being cast ashore.

Hogging and arching.

A vessel whose weights and displacements are so disposed as to render her subject to a strain of this kind beyond what the strength of her upperworks will enable her to bear, will assume a curved form.

The centre is curved upwards by the excess of the pressure beneath it, and the ends drop, producing what is called

Practical Building.

"hogging." The main remedy for these evils, as before stated, is in the strength of the deck and upperworks, and their power to resist a tensile strain. There is seldom a want of sufficient strength in the lower parts of the vessel to resist the crushing or compressing force to which it is subjected. The decks of vessels should not, therefore, be too much cut up by broad hatchways; and care should be taken to preserve entire as many strakes of the deck as possible. The tensile strength of iron can be brought to bear most beneficially in this respect, and some continuous strakes of it laid upon the tops of the beams and below the deck-plank would add materially to the strength of all ships. Deck-planking has been sometimes laid diagonally at an angle across a ship, but it will be evident, from these remarks, that the value of the longitudinal tie is thereby much lessened, and there is no sufficient corresponding benefit of any other kind to justify the whole deck being laid in this manner.

Great sheer, or rising of the deck, fore and aft, is objectionable, from its lessening the strength of the longitudinal tie, though it is much practised, as it gives a lively appearance to a ship, and hides the defects of hogging if it should occur.

In the whole of the upper parts of a ship, as well as in the deck, every means should be taken to increase the power of resisting tension. In a wooden ship the upper part of the frame should be chain-bolted wherever the continuous range of bolts can be placed so as not to interfere with the in and out fastenings; and the shifts of the different wales, and other parts, which act as longitudinal ties, should be carefully attended to. The waterway-planks and shelf-pieces are also most important, and their continuity should be maintained throughout the length of the vessel, with as little diminution of strength as possible, at the junction of the different lengths.

In iron-vessels the parts corresponding to these are particularly important, as the plating exposes a very weak edge at the top, and is liable to be torn down if this edge be not well guarded and supported. To enable the lower part of the ship to resist the compression to which it is subject, the spaces between the frames in the best built wooden vessels are filled in solid, so as to make, as far as possible, an incompressible mass. The various abutments of this part of the body should be as closely fayed or fitted as possible. In iron-vessels, as the spaces between the frames cannot be filled in solid, the keelsons should be of great strength. The power of wrought-iron to resist compression, when it is prevented from buckling, is here of great value, as the fastening of the keelson to every frame as it passes gives stiffness and rigidity to it, and consequently great power to resist compression.

Though these are the strains to which a ship is most likely to be exposed, it by no means follows that there are no circumstances under which strains of the directly opposite tendency by recoil, when pitching and tossing, or otherwise, may be brought to act upon the parts. The weights themselves in the centre of the ship may be so great that they may have a tendency to give a hollow curvature to the form, and it is therefore equally necessary to guard against this evil. When this occurs, the vessel is technically said to be "sagged," in distinction to the contrary or opposite change of form by being hogged. The weight of machinery in a steam-vessel, or the weight or undue setting up of the main-mast, will sometimes produce sagging. The introduction of additional keelsons tended to lessen this evil, by giving great additional strength to the bottom, enabling it to resist extension, to which, under such circumstances, it became liable; and as the strain upon the deck and upperworks becomes changed at the same time, they are then called upon to resist compression. In iron-vessels, the waterway-planks and shelf-pieces are again, in this case, very important to aid in resisting this strain. The deck-planks may become shortened by the deck assuming a curved form in the middle of the length of the ship, the beams yielding and working with them; and a crushing strain is then brought to bear upon the plating of the topsides, which they are not calculated to sustain. Some light flat-bottomed river-steamers of iron with very full lines forward and aft, have given way from this cause. The best practical lesson upon the subject, and the most direct proof of the want of strength of iron-vessels at the topsides, if constructed without additional strengthening there, was given by the Nemesis when her topsides opened, as so well described by Captain Hall in his account of her voyage to India, and when he so judiciously strengthened her by attaching balks of timber longitudinally to the two sides.

A corresponding action to that described as hogging takes place in relation to the breadth of the vessel, but more particularly in the case of men-of-war, on account of the weight of the ordnance concentrated along the sides. The central portion of the body is subjected to an undue upward pressure, while the outer portions are strongly acted upon by the weight there tending to depress and immerse them. The effects of this action may be greatly modified by the form of the vessel; longitudinally, it produces the upward curvature previously referred to; and transversely, it tends to separation of the sides, except in three-decked or very lofty ships, in which, if the tumbling home be very great, the tendency is to produce a separation at the main breadth and below it, and a collapsing of the sides above it.

Horizontal pressure of the water.

Another force tending to alter the form of a vessel arises from the horizontal pressure of the water on the sides of the vessel. The sides are compressed or forced together, and the tendency produced is to add to the curvature of the deck amidships, and increase the hogging both longitudinally and transversely.

Forces which affect a ship in motion.

When a ship is in motion, if the surface of the sea be very uneven, so that her passage will be over the waves, the supports become very variable, and the opposing forces of upward pressure and gravitation will have a tendency to produce corresponding changes in the form of the body; and if the motion of the ship be violent, and thus produce any sudden shock or jerk, the strain upon the materials and upon the fastenings will become immeasurably increased.

Force of the waves.

When the ship is on a wind, the lee-side is subjected to a series of shocks from the waves, the violence of which may be imagined from the effects they sometimes produce in destroying the bulwarks, tearing away the channels, &c. The lee-side is also subjected to an excess of hydrostatic pressure over that upon the weather side, resulting from the accumulation of the waves as they rise against the obstruction offered by it to their free passage. These forces tend in part to produce lateral curvature. When in this inclined position, the forces which tend to produce hogging when she is upright also contributes to produce this lateral curvature. By experiments made on her Majesty's ship Genoa, in 1823, by Mr Moorsom, a member of the late school of naval architecture, he ascertained that this lateral curvature amounted to $1\frac{1}{2}$ inch on each tack, making an alteration of form to the extent of 3 inches from being on one tack to being on the other.

Tension of the rigging

The strain from the tension of the rigging on the weather side when the ship is much inclined is so great as frequently to cause working in the topsides, and sometimes even to break the timbers on which the channels are placed. Additional strength ought therefore to be given to the sides of the ship at this place; and in order to keep them apart, the beams ought to be increased in strength in comparison with the beams at any other part of the ship.

Practical Building.

It has been proposed to introduce tie-rods from the channels to the step of the mast, so as to render each mast and its supports a combination of struts and ties with the strains self-contained. This may be explained by the annexed figure.

Let AB represent the deck-beam, or beams of the ship at

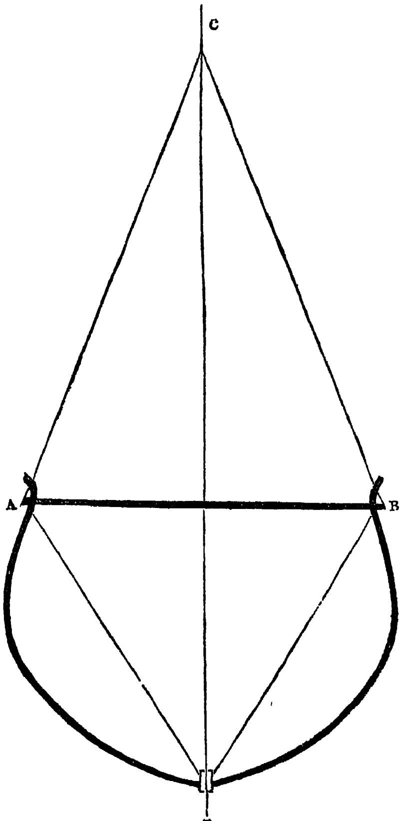

Fig. 28.

the channels, CD the mast, and AC and CB the shrouds. Now, if the ties AD and BD be introduced, it is evident that any additional strain brought upon AC or CB will be transferred to AD or BD, and resisted independently of any strength in the sides of the ship, so long as AB the beam, and CD the mast, are rigid and do not bend. By this system, also, any excessive strain is prevented from being brought upon the step of the mast at D, producing sagging, by setting up the rigging unduly. Though the ties AD and BD cannot conveniently be introduced in ships in direct lines, as shown in the woodcuts, the principle proposed may yet be brought into play by curved ties of sufficient stiffness not to straighten under the tensile strain to which they will be exposed.

General remarks on disturbing forces.

These are the principal disturbing forces to which the fabric of a ship is subjected; and it must be borne in mind that some of these are in almost constant activity to destroy the connection between the several parts. Whenever any motion or working is produced by their operation between two parts, which ought to be united in a fixed or firm manner, the evil will soon increase, because the disruption of the close connection between these parts admits an increased momentum in their action on each other, and the destruction proceeds with an accelerated progression. This is soon followed by the admission of damp, and the unavoidable accumulation of dirt, and these then generate fermentation and decay. To make a ship strong, therefore, is at the same time to make her durable, both in reference to the wear and tear of service and the decay of materials. It is evident from the foregoing remarks, that the disturbing influences which cause "hogging," commence their action at the moment of launching the ship, and are thenceforward in constant operation. As this curvature can only take place by the compression of the materials composing the lower parts of the ship, and the extension of those composing the upper parts as more particularly explained when treating of the strength of beams, the importance of preparing these separate parts with an especial view to withstand the forces to which they are each to be subjected cannot be overrated by the practical builder. The side of a ship is, however, in a somewhat different position from the plate or web of an ordinary plate-beam, or the sides of a box-beam, on account of the horizontal pressure of the water against it; and because in deep ships, with one or more intermediate decks, some of the strain is brought upon it in the middle of its depth. The position of the neutral axis or line between those particles exposed to a crushing and those exposed to a tensile strain, is therefore very difficult to determine; but from a consideration of the circumstances just mentioned, it must be higher in a ship than theory would place it if the ship were considered in the light of an ordinary beam exposed to strains brought upon it in the ordinary way.

Diagonal trussing as a means of resisting strains.

The importance of the system of diagonal trussing and bracing in ship-building appears to have been first fully appreciated by Sir Robert Seppings, and the principle on which it should be introduced to have been first explained by him. It is obvious that if four pieces of timber be put together, so as to form a square, or a rectangular parallelogram, with their ends connected by a round pin only at each corner, they may assume the form of any other parallelogram whose sides are of the same length, but that in so doing the length of the two diagonal lines will be altered; thus—

In both of the annexed figures, the sides are of the same length, but AC of fig. 29 is shortened into ac in fig. 30, and BD of fig. 29 is lengthened into bd in fig. 30. The introduction, therefore, of diagonals of a fixed or unalterable length into any piece of frame-work will tend to prevent alteration of form, and it will be perceived that the duty required of the two diagonals in resisting any change is different, the one being required to resist extension, and the other to resist compression. One diagonal only is sometimes considered sufficient, but in this case care must be taken that the material of which it is composed, and the manner in which it is applied, be such that it may be fit to resist either extension or compression, if the frame-work is liable to be alternately strained in either direction. In any piece of frame-work, however large, a straight wrought-iron bar is excellent as a tie, but as a strut it would be nearly useless on account of its liability to bend. Wrought-iron, however, is the material chiefly used in diagonal bracing; and it may be used with propriety for both diagonals, wherever on account of liability to a strain in both directions two are used, because each in its turn will resist extension, and that diagonal which is exposed to compression will be protected from injury by the resistance of the other to extension. The sides of a ship may be supposed to be divided into a number of pieces of frame-work of imaginary outlines or dimensions. Those embraced in the midship body may be supposed liable to be strained in both directions; but the upper portions of those composing

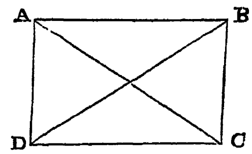

Fig. 29.

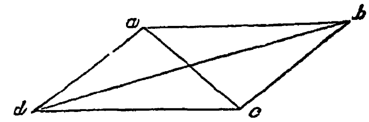

Fig. 30.

Practical Building.

the fore and after bodies will be inclined to fall forward and aft respectively; and if this tendency only is to be guarded against, the ties must be placed in different directions in the two bodies sloping up from below from amidships forward and aft in parallel lines, extension being the force which they will be called upon to resist. The system is not so much required in the bottom of a ship. In the decks diagonal trussing, placed diagonally across a ship, is advantageous as tending to prevent the ship working, by one side advancing or receding alternately with the other, and here the diagonals should be made to cross each other and lie in both directions.

Diagonal trussing, as used by Sir Robert Seppings, was introduced into some ships as a series of frame-work along the centre of the ship, from pillar to pillar, from the keelson to the decks, and he arranged these on the principle of depending upon struts and not upon ties. Wrought-iron was then much less used than in the present day, and timber forms an excellent material for a strut, weight for weight, in comparison with solid iron-bars, on account of its dimensions giving it stiffness. Struts are also convenient because they require comparatively little attention to the fastening of their ends. They abut against a surface, or into a corner, and their ends are easily prevented from shifting. With ties this is very different; their ends must be made sufficiently secure to resist a strain equal to their whole strength.

Before the introduction of this system, it was no uncommon thing to find ships hogged to the extent of from two to three feet. An instance is quoted in Portsmouth dockyard of an old ship, whose keel was curved upwards to the extent of two feet or more, and which was grounded in dry-dock on a set of blocks laid level. She straightened as she settled upon them, and diagonal trussing being then introduced, it was found to support her in a remarkable degree, when she was again floated. In this case the trussing was applied chiefly in midships, from pillar to pillar, from the keelson to the deck-beams.

In iron-ships diagonals are not so much required on the sides of the ship, because the plating being a connected surface of equal or nearly equal strength in all directions, it is incapable of motion in its parts, and the line of any supposed diagonal is incapable of extension otherwise than by a force sufficient to tear the plating asunder.

Comparison of iron with wooden vessels.

A general consideration of all the strains to which ships are subjected naturally leads to the question of selecting the material which is best adapted to resist them. In treating of the materials used in ship-building, especial reference was had to the various qualities possessed by each, which rendered them more or less valuable individually or collectively. It may perhaps be expected, that before leaving this part of the subject a more direct comparison should be drawn than has yet been done between the relative merits of wood and iron vessels, and that the points in their structure, in which they chiefly differ in strength and safety, should be pointed out. The advocates of either system will, no doubt, discover many errors and omissions in the remarks on this subject, which have been made, or which may now be made; but they are given as the results of close observation and experience for a period of upwards of twenty-five years of practical connection with both classes of vessels. It may at the same time be stated with respect to this treatise, that while the increase of steam-vessels, and the great alterations in the forms of ships since the publication of the previous edition of the *Encyclopædia Britannica*, had to be considered, much of the alteration from the previous very able article on this subject, by the late Mr Crueze, is caused by the necessity of now treating of iron-ships equally with those of wood. An endeavour has been made to introduce as much information respecting iron-vessels, in addition to as full information respecting wooden vessels, as the assigned limits would permit; and the substance of the article by Mr Crueze has been retained in many points, and free use has been made of it wherever desired, so as to form, as far as may be, a concise and consecutive treatise.

Basis of comparison.

If strength alone were to be assumed as the basis of comparison, without reference to weight or cost, it would probably be conceded that a stronger vessel could be built of iron than it would be possible to construct by any combination of wood. It will, however, be more practically useful to compare vessels of about equal weight, or equal cost or strength.

Frames.

An individual frame in an iron-vessel is formed with more continuity of strength throughout its length, than is the case in a wooden vessel, and greater opportunity is given of obtaining strength, no matter what may be the form of the body. By the variety of form into which iron can be rolled by the manufacturer, opportunity is also given to obtain the desired strength with less useless material.

Sheathing.

In the sheathing, whether internal or external, much greater difference exists. In wooden vessels the planks are laid side by side, and with few exceptions are not fastened or connected with each other; indeed they are forced asunder by the caulking required to make the joints between them water-tight. Their only connection therefore is by means of the fastenings which unite them to the frames. The plating of an iron-vessel, on the contrary, is made into one completely connected surface, and even if all the frames were removed, it would remain in shape, and would still form a vessel of great strength and stiffness. The fastenings, also, to the frames will not bear comparison, the power of iron to resist shearing across being so much greater than that of treenails or copper-bolts.

Resistance to bulging force by iron.

The power of iron-plates to resist a force similar to that to which they would be subjected if an iron-vessel took the ground on a hard bottom, with some projecting points of rock or stones, was also experimented on by Mr Fairbairn. The plates were placed upon a frame, leaving a space of 1 foot square, unsupported, and on the centre of this a bar of iron, 3 inches diameter, with its end rounded, was brought to bear. Plate $\frac{1}{4}$ inch thick was burst with a force of 16,779 lb., and a plate $\frac{1}{2}$ inch thick, bore a strain of 37,723. The plate of double the thickness, therefore, bears more than double the pressure. The power of timber to bear a similar strain was tested at the same time. Oak planks, 3 inches thick, were burst with a force of 17,933 lb., or only a little more than was required to burst the same surface of a plate $\frac{1}{4}$ inch thick. Oak planks, of $1\frac{1}{2}$ inch thick, were burst with 4406 lb. A plank of double the thickness, therefore, bore much more than double the pressure, the proportion being as the squares nearly.

by timber.

Beams.

Beams of iron are applicable to both classes of vessels, and their superiority is now becoming so generally acknowledged, that they are being largely used in wooden vessels in the merchant-service and in the French navy. It is, however, to the results of the combination of these materials as a whole that consideration must chiefly be given. Unfortunately there are no want of instances of both species of vessels going to pieces suddenly when cast on shore on rocks; and until iron-vessels are double-plated with an interior water-tight sheathing, wooden vessels, with solid bottoms of floors and futtocks, will probably give greater security in such a position for a short period of time if the sea be rough, and for a greater period if it be smooth; on a flat beach, however, iron-vessels seem undoubtedly to have the advantage. The Great Britain, lying for a whole winter on the coast of Ireland, and the Vanguard, lying ashore for several days on a rocky beach, are two notable instances of iron-vessels having come off comparatively uninjured, after having been exposed to strains which it is believed no wooden vessels could have undergone. There

General strength.

are, at least, no such instances on record with regard to them. As another direct comparison, the Demerara may be mentioned as a wooden vessel which, after being launched, grounded in the river at Bristol while being brought down, and she was so much injured that she was condemned; whereas the Australia, an iron-vessel, on first coming down the Clyde grounded in a similar manner, lying right across the river in one of its narrowest parts, but she came off quite uninjured. Another instance of strength, such as no wooden vessel has ever exhibited, may be quoted in the case of an iron-vessel which, on the occasion of her being launched, stuck on the ways which were upon a high wharf above the water, and more than one-third of the whole length of the vessel was left totally unsupported, overhanging the wharf, and yet she did not break or receive any damage.

The same elements of strength which enabled these vessels, especially the Great Britain and the Vanguard, to withstand the strain to which they were exposed, will also be efficacious in preventing a vessel straining at sea in a heavy sea-way, so as to become leaky and founder at sea from this cause. From a consideration of such facts as the foregoing, the general opinion appears to be, that iron-vessels, as a whole, are not only stronger than wooden vessels, generally speaking, but that they may be made of greater or equal strength, with considerably less weight of hull. The extent to which this saving of weight may be carried, without impairing the strength to an improper or unsafe degree, will always be a subject of inquiry to the iron ship-builder; but if he err in judgment and produce too weak a ship, the error must be attributed to him, and the material must not be considered to be in fault.

The power of fitting water-tight bulkheads to iron-vessels is also a great advantage, and will be a source of much greater security hereafter, when vessels are better built than they have hitherto been. Their importance, and the great additional safety which they impart, are evident, and the principle may be carried out to any extent, and this longitudinally as well as athwartship. In the after part of screw-ships, the passage alongside of the shaft to the propeller may be made water-tight, and communication with the engine-room may be cut off, if it be desired, and if proper arrangements be made for this purpose. These bulkheads also form a good protection against the very rapid spreading of fire, and in the case of any vessels particularly liable to this danger they might be made double, and water be admitted between them.

The durability of iron-ships has been already referred to, as far as regards ordinary tear and wear; but their superiority in the event of injury by collision, or by being on shore, is still more marked. If a few frames or floors are broken in a wooden vessel, the amount of work required to be entered into to replace them is very great, a large portion of the plank in the neighbourhood requiring to be ripped off. In an iron-vessel, on the contrary, a new piece of frame can be put in to replace the injured part, and the whole made as strong as before, by lapping pieces. And in the sheathing, an injured plate, or a piece of a plate, can be cut out and replaced without disturbing any of the other work.

on-vessels for rposes war.

For purposes of war iron-vessels have been pronounced by some as unfit, the reasons given being, that the iron when struck flies into innumerable small pieces, which would be most destructive to the men on board; and that in the event of a shot passing through the ship and striking the further side, the plates being no longer supported by the frames, but depending upon the rivets only, are apt to be torn off in large pieces. In some experiments made at the Royal Arsenal at Woolwich, in 1844, by the late General Dundas of the Royal Artillery, it was found that the splinters resulted equally whether the plates fired at were of the best Lowmoor iron or of common boiler-plate. A thickness of 12 to 15 inches of wood was found to stop almost the whole of the small splinters; and a less thickness of a material composed of a mixture of saw-dust and India-rubber effected the same object. With a shot fired with no greater velocity than would just enable it to penetrate the $\frac{5}{8}$ plates, the splinters were fewer; and at the edges of the hole through which the shot had passed, the plate was bent back with ragged edges. In some experiments in Portsmouth harbour, an iron target was fired at, with a screen of canvas behind it to show the splinters, and the same results were obtained. In both cases the plates were $\frac{1}{2}$-inch and $\frac{5}{8}$-inch thick. In iron-vessels, therefore, constructed for the purposes of war, if composed of plates of ordinary thickness, it would be judicious to line them with wood to prevent the men being exposed to the risk of such splinters. In ordinary gun-boats, or corvettes, where the men are above the hull of the ship when fighting the guns, this danger is obviated, and a portion of the ship might also be protected to any extent that might be considered desirable. The present changing state of the science of projectiles renders it difficult to provide against all contingencies; but plates of only ordinary thickness will stop all ordinary shells. This is a most important difference, as these, in their various forms, are now the most dangerous to a ship, and iron-vessels may therefore, on this account, lay claim to great consideration as adapted for warlike purposes. If the iron-vessel, then, be so constructed that it can be penetrated by solid shot only, it would become a question of a wooden vessel being burnt or destroyed by shells, or of an iron-vessel being sunk; and it is believed that many would prefer the latter risk. A shell bursting on board, or in the side of a wooden vessel, would cause greater injury and loss of life than the splinters from the shot in an iron-vessel, and these, as has been said, might be lessened in a large vessel, and avoided in the smaller vessels. It was the opinion of many naval officers respecting the effects shown by the experiments at Portsmouth, that if the same number of shots had been fired at targets of wood, the canvas screen would have been swept bodily away, and that such parts of the targets themselves as remained would have been reduced to a mass of fibres, without strength to sustain themselves or resist any strain or pressure whatever. If iron-vessels hereafter show such great superiority in strength and safety at sea, or when cast on shore, or in durability, as to make their introduction into the royal navy important on these accounts, it may then become a question whether a system may not be introduced of constructing the whole of the lower part of the vessel of iron, up to the neighbourhood of the water-line, and that the portion of the vessel above this, where the men would be exposed to the splinters, should be of wood. The iron-frames could be continued up for some distance alongside of the wooden frames, and there are no practical difficulties in such a system that could not be overcome.

PRACTICAL OPERATIONS.

Commencement of practical operations.

After the cursory view which has been taken of the strains to which ships are liable, and the general remarks which have been made on the points to be attended to in their construction, it is now proposed to give a short outline of the proceedings in the actual building of the vessel.

Laying off.

The term "laying off" is applied to the operation of transferring to the mould loft-floor those designs and general proportions of a ship which have been drawn on paper, and which have been previously referred to, and from which all the preliminary calculations have been made and the form decided. The lines of the ship, and exact representations of many of the parts of which it is to be composed, are to be delineated there to their full size, or the actual or real dimensions, in order that moulds or skeleton outlines may be made from them for the guidance of the workmen.

Practical Building.

These working drawings are made by projection, and are not views of the parts as they appear to the eye. In a projected drawing the eye is supposed to move and be directly opposite to each line, as it, in its turn, is represented by the draughtsman. Separate drawings must, therefore, be made for the different faces of any object which are at right angles to each other.

The delineation in this manner of solids of a complicated form is of itself a science, and one which is now attracting much more attention than formerly. It is very ably treated by the Rev. Dr Woolley in a work entitled *Descriptive Geometry*. Before the publication of this work the efforts in this direction in this country had been chiefly made by practical men, each showing the mode of delineating the more difficult objects in his own art. Architectural works showed the mode of delineating the mouldings and details of the columns of the seven orders of architecture. Books on carpentry showed the mode of working and laying off a geometrical or winding staircase, and works on ship-building included, at great length, the modes of laying off complicated and irregularly formed parts. To show the mode of delineating not only the frames, but all the pieces of varying form which are required in the bows or sterns of ships, would be far beyond the limits of this treatise. It is impossible to include either a complete treatise on drawing or a complete set of delineations of the modes of combining the whole of the various minute parts of which all classes of vessels of wood and of iron are composed.

A proper knowledge of the minutiæ of construction and of workmanship can only be obtained by practical experience upon the work itself; and the form and combination of the parts will continually vary with the variations in the form and outline of the bodies and of the heads and sterns of the ships.

Principal plans. The principal plans of a ship are the sheer plan, the body plan, and the half-breadth plan, and these have been already fully discussed, and their uses explained. In addition to these plans it is customary to furnish the architect with a profile of the inboard works, showing the disposition or distance apart, and the appearance of the timbers which constitute the frame, also the length or the heads and heels, and general arrangement of the floors and futtocks, the midship section, on which is described the moulding or athwartship size of the timbers, the thickness of the exterior and interior planking, the connection of the beams to the side, the dimensions of the waterways and shelf-pieces, and the forms and fastenings of the knees, &c. These, with a scheme of scantlings containing the dimensions and other particulars of the principal pieces which enter into the construction of the fabric, constitute all the preparatory information required by the builder. In private contracts very full information on all these points is generally included in the specification.

Fore and after bodies. A ship is generally spoken of as divided into fore and after bodies, and these combined constitute the whole of the ship; they are supposed to be separated by an imaginary athwartship section at the widest part of the ship, called the midship section or dead-flat.

Midship body. The midship body is a term applied to an indefinite length of the middle part of a ship longitudinally, including a portion of the fore-body and of the after-body. It is not necessarily parallel or of the same form for its whole length.

Square and cant bodies. Those portions of a ship which are termed the square and cant bodies may be considered as subdivisions of the fore and aft bodies. There is a square fore-body and a square after-body towards the middle of the ship, and a cant fore-body and a cant after-body at the two ends. In the square body the sides of the frames are square to the line of the keel, and are athwartship, vertical planes. In the cant bodies the sides of the frames are not square to the line of the keel, but are inclined aft in the fore-body, and forward in the after-body. The reasons for the frames in these portions of a wooden ship being canted, is that, in these parts of the ship, the timber would be too much cut away on account of the fineness of the angle formed between an athwart ship plane and the outline or water-lines of the ship. The timber is therefore turned partially round till the outside face coincides nearly with the desired outline, and it is by this movement that the side of a frame in the cant fore-body is made to point aft, and in the cant aft-body to point forward. This will be best understood by the annexed figure, showing an exaggerated horizontal section of a frame in the fore cant-body, the dotted line representing the extent to which the timber would have been cut away if it had been placed square to the line of keel, and if the

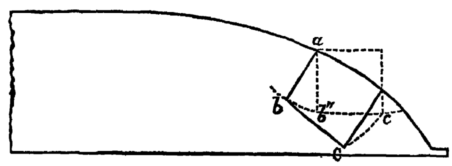

Fig. 31.

side $a\,b$ had not been "canted" aft, turning on the point or edge a.

In wooden ships the term "timbers" is sometimes applied to the frames only, but more generally to all large pieces of timber used in the construction. Timbers, when combined together to form an athwartship outline of the body of a ship, are technically called frames, and sometimes ribs. In iron-ships the frames are composed of iron-bars of various forms.

Moulding and siding. The terms moulding and siding are nearly synonymous with thickness and breadth, observing that the moulding of a piece of timber is the dimension of the side on which the mould is applied for determining its shape or curvature. For instance, the moulding of a beam is its length and thickness; its siding is its fore and aft dimension or breadth.

Room and space. Room and space is a certain distance determined by the fore and aft dimensions, or the siding of two adjacent timbers, together with the opening between them. It is generally defined as the distance from centre to centre of the frames, or from centre to centre of the spaces between them. The centre line between two adjacent frames is called the joint.

Shift. Shift in its general sense is applied to a certain arrangement among the component parts of a ship. Thus a shift of deadwood, or a shift of plank, means the disposition of the buts of the timber or plank with reference to the longitudinal distance of one joint from another, and this with respect both to strength and economy.

Bevellings. The bevelling of a timber is the angle contained between two of its adjacent sides. Bevellings are either acute angles, right angles, or obtuse angles. These three separate cases are denominated under bevellings, square bevellings, and standing bevellings.

Sirmarks. Sirmarks are certain points or stations marked on the mould of the timbers, at which the bevellings are applied, in order to cut the timber to the bevelling required at that spot. These sirmarks are determined, and their positions denoted in the body plan, by the various diagonal lines.

Water-lines and level-lines. Water-lines in the sheer plan, are lines drawn parallel to the surface of the water (Plate III.) Level-lines are similar to water-lines, except that they are drawn parallel to the keel instead of to the water (Plates V. and VI.) In the half-breadth plans, the water-lines or level-lines show the outline of the form of the ship at sections at the corresponding heights in the sheer and body plans.

Diagonal lines. Diagonal lines, as shown in the body plan and half-breadth plan (Plate III.), and marked 1 D, 2 D, 3 D,

Practical Building.

show the boundaries of various sections which are oblique to the vertical longitudinal plane, and which intersect that plane in straight lines parallel to the keel. In wooden ships, the position of the diagonal lines drawn in the body plan is not arbitrary, because it has reference to the different timbers of which the frame is composed, and also to the station of the ribands and harpins. The number of diagonals is increased in the deeper class of vessels. They are drawn to show the lengths of the floors and futtocks, together with the heights of their heads and heels above the keel, and are marked floor-head, &c. Diagonals, marked as 1st sirmark, 2d sirmark, 3d sirmark, &c., or 1 D, 2 D, 3 D, on the body plan (Plate III.), show the heights and situation of the harpins and ribands which are used to give support to the ship whilst in frame. In wooden ships they are always placed between the heads of the respective timbers.

Diagonals on sheer plan.

The following is the mode of setting off the diagonals in the sheer plan:—Take the perpendicular heights in the body plan, that is, the heights square to the upper edge of the keel of the intersection of the diagonal with each of the transverse sections, and transfer these heights to the corresponding section in the sheer plan. Through the points thus obtained draw a curve, which will be the line required.

Diagonal on half-breadth plan.

To transfer the diagonals to the half-breadth plan: observe the point of intersection of the diagonal on the body plan with each transverse section, and take the horizontal distance of each of these points from the middle line, and transfer it to the corresponding section in the half-breadth plan. Through the points thus obtained draw a curved line, which will represent the horizontal line of the diagonal. After these lines have been added to the sheer, body, and half-breadth plans on paper, the transference to the floor, where the ship is to be delineated to the full size, is easy.

It is the duty of the draughtsman in the mould-loft floor to fair the body, if any of the curves shown by the lines previously drawn on the paper do not appear of easy and good forms, when represented of their full size.

Every form to be drawn on the floor, and its beveling obtained.

On the mould-loft floor it is necessary, in iron-ships, to draw out every frame, so as to be able to give the particulars to the workmen; and it is not only necessary to give them the outline of the frame, but also the beveling or the angle which the outer surface makes with the side at each spot or sirmark. This is obtained from the half-breadth plan at the various points where the different level lines or diagonal lines cross each frame. A variety of modes are practised by different builders of iron-ships to convey this information from the mould-loft to the workmen, instead of using moulds, as almost universally practised by builders of wooden ships. Great accuracy in this respect is required in iron-ships, as in them no dubbing off or pairing the body by the adze is practicable.

Expanding the body.

Expanding the body so as to represent the whole of the planking or outer skin or surface of a ship, is another process connected with laying off; and it is particularly important to the iron ship-builder, as it enables him to obtain the necessary iron-plates from the rolling-mills of the exact widths and lengths that will be required. This is done by drawing a line, to represent the line where the plates meet the keel and stern-posts. On this line the station of any number of frames that may be necessary to give the desired degree of accuracy must be set off, and at these stations lines must be drawn of a length equal to the girt or outline of the frame at that station; this length will be obtained from the body plan. The number of strakes to be used in planking or sheathing the ship must next be determined and be set off accordingly, on the lines representing the different frames; and great art is necessary in this operation, as upon these lines much of the beauty of a ship depends to please the eye of a connoisseur. The shift or the distances between the ends of the different plates may also be determined and marked in this plan, and thus the length, width, and breadth of every plate may be accurately ascertained.

The circumference of the bottom being much larger at the midship part than toward the extremities—that is, at the bow and buttock—the lines for the strakes taper as they recede from midships. They also acquire an upward curve, called "Sny," which renders it difficult to work the plank. When the sny becomes too great, a strake is ended short of the others, and this is termed a "stealer," as it diminishes the sny for the succeeding strakes. Under the buttock it is often necessary to work some of the after-plank wider at the after-end, and this has the same effect of diminishing the sny of the following strakes. "Hang" is the exact reverse of "sny." It mostly occurs in working plank on the inner surface of the timbers, and outside above the main breadth.

"Sny."

With regard to the practical operations in building a ship, nothing more can be attempted here than a few general observations on the principal parts of a ship, and the mode of putting them together, to resist the various strains to which each part will be subjected. The practice in her Majesty's yard will be found very fully explained in Fincham's outlines of shipbuilding, and in a very excellent treatise by Mr Peake, now master-shipwright at Devonport. Some details of wooden ships of the ordinary system of construction will be first described.

The keel

The keel of a ship built in this country is generally composed of elm, on account of its toughness, and from its not being liable to split if the ship should take the ground, though pierced in all directions by the numerous fastenings passing through it. It is generally composed of as long pieces as can be obtained, united to each other by horizontal scarphs. These scarphs are made sloping up from the bottom to the upper surface, on which the floors rest. But the strain to which a keel is subjected has a tendency to curve it up or down, and not sideways. These scarphs should, therefore, be made vertical, in the same manner as scarphs of the beams, as there can be no doubt that the vertical scarph will give the greatest strength to resist a strain in this direction.

Rabbet of the keel.

The rabbet of the keel is an angular recess cut into the side to receive the edge of the planks on each side of it. In the government service this rabbet is made of greater breadth vertically, so that the plank to fill it is required to be of such great thickness that it altogether loses the character of a plank, and becomes a stout massive piece of timber. This arrangement was introduced by Mr Lang, and has been denominated Lang's safety keel. It gives great additional strength to the bottom of a ship, and great lateral support to the keel, when the ship takes the ground and rests on the edge, as the leverage to displace it sideways is thus reduced.

In the merchant service the rabbet is seldom carried so low down on the side, and the garboard strake or strakes are not so thick. The keel forward is connected to the stem by a scarph, sometimes called the boxing scarph, and aft to the stern-post, by mortice and tenon. The apron is fayed or fitted to the after-side of the stem, and is intended to give shift to its scarphs, the lower end scarphs to the deadwood. The keelson is an internal line of timbers fayed upon the inside of the floors directly over the keel, the floors being thus confined between it and the keel. Its use is to secure the frames and to give shift to the scarphs of the keel, and thus give strength to the ship to resist extension lengthways, and to prevent her hogging or sagging. The foremost end of the keelson scarphs to the stemson, which is intended to give shift to the scarphs connecting the stem and keel. The frames or ribs are composed of the strongest and most durable timber obtainable. By Lloyd's rules

Practical Building.

a durability of twelve years is assigned to frames composed of English, African, and live oak, East India teak, Morning Saul greenheart, morra or iron-bark; of ten years to mahogany of hard texture, Cuba, sabicu, and pencil cedar; of ten years for floors and first futtock, and nine years for second and third futtocks and top timbers, to Adriatic, Spanish, and French oak; of nine years to red cedar, angelly and Venatica; of nine years for floors and first futtocks, and seven years to second and third futtocks and top timbers of other continental white oaks, Spanish chestnut, stringy bark, and blue gum; of eight years and seven years respectively, as before, for North American white oak and American sweet chestnut; of seven years for larch, hackmatac, tamarac and juniper, and pitch-pines.

Floors.

The floors in the government service are carried across the keel with a short and long arm on either side alternately, so as to break joint, and between the frames the space is filled in solid.

Shelf-pieces.

Longitudinal pieces of timber are worked round the interior of a ship for the purpose of receiving the ends of the beams of the several decks; they are called shelves, and are of the greatest importance, not only for this purpose, but also as longitudinal ties and struts. In any system of diagonal bracing, properly carried out, they should form one side of the parallelogram or of the triangle, and those other timbers, or iron-bars, which form the diagonals or the other sides of the parallelogram or triangle ought to be firmly secured to them. A thick strake of plank used formerly to be worked between the shelf and the timbers or frames, but now it is generally worked home upon them. The shelf is generally supported by some thick strakes of plank worked immediately under it, and formerly it was also sometimes supported by chocks or triangular pieces, like brackets on the ship's side, brought out to be flush with the inner edge of the shelf, and on the face of this an iron-knee. This chock is now generally dispensed with, and the lower side of the shelf is bevelled off towards the ship's side, and the iron-knee is forged to fit under it accordingly. These fastenings will be referred to when treating of the means of securing the ends of the beams. The other fastenings of shelf-pieces are by numerous through-bolts. Timbers which are fayed to the inside of the frame, or upon the inside of the plank, longitudinally or diagonally, solely for the purpose of supporting the frame, are called riders.

The beams.

The beams of a ship prevent the sides from collapsing, and at the same time carry the decks. The beams are spaced, and their scantling settled upon, according to the strength required to be given to the decks, and to suit the positions of the masts and hatchways, and other arrangements connected with the economy of the ship. All beams have a curve upwards towards the middle of the ship called the round up. This is for the purpose of strength, and for the convenience of the run of the water to the scuppers. Wooden beams are single piece, two, three, or four piece beams according to the number of pieces of timber of which they are composed. The several pieces are scarphed together, and dowelled and bolted, the scarphs being always vertical. A scarph now very generally adopted was introduced by Mr Edye, late master-shipwright of Devonport dockyard, and is represented in the annexed figure.

Edye's Beam.

Fig. 32.

The beams of ships being supported at both ends, and one of the strains to which they are chiefly subjected being a downward pressure, the upper part of the beams will then be compressed, and the lower parts extended. It is therefore desirable that the lower part of the beams should not be wounded so as to cut the fibres across in that part. An incision above the line of the vertical axis is of less moment, and if an incision be made there for the purpose of introducing a carling, for instance, and if this be well fitted, and be of as hard wood as the beam, the strength of the beam will not be impaired, but may even be increased.

Connection of the beams to the sides of the ship.

The connection of the ends of the beams to the sides of the ship have been made in various ways. The points to be considered, with reference to this connection, are, that the beam is required to act as a shore or strut, to prevent the sides of the ship from collapsing, and also as a tie to prevent their falling apart; that the beam shall not rise from its seat, and that it shall not work in a fore and aft direction; that the beam may be an effective shore, nothing more is necessary than that the abutment of the end against the ship's side may be perfect.

In order that it may act as a tie between the two sides, it is generally dowelled to the upper surface of the shelf on which it rests; and the under surface of the water-way plank which lies upon it is sometimes dowelled into it. These dowels, therefore, connect it with the shelf and the waterway, and through this means it is thus connected with the sides of the ship. There is, also, in the ships of the royal navy, a plank called a side-binding strake, scored down over and into the beam-ends at some distance from the side, and bolted through the side between the beams. The scoring into the beams connects the in and out fastenings of this strake with the longitudinal tie of the beams, but the advantage does not seem to be commensurate with the labour.

Knees to beams.

The beams are also supported by knees below them. Wooden knees are chiefly used in America; and it is argued that they give a better support to the beam from their greater surface, and from their stiffness in the throat, or angle of the knee. The iron-knees used in the royal navy vary in form; they are made not only to support the beam from below, but sometimes with horns to clasp it sideways at a short distance from the side of the ship. The lower arms of these knees are so formed as to fit round the shelf; or sometimes, with a view to prevent the necessity of working the iron into this form, and at the same time afford additional support to the shelf, a chock is fitted under the shelf to receive the face of the knee. While the knee is instrumental in supporting the beam, it is also upon it that dependence is mainly placed to prevent the beam rising, or working in an upward direction. In these fastenings there appears a want of any very efficient means to prevent the beam straining in a fore and aft direction, or working upon the end as upon a pivot.

Strains which a beam must resist.

From the short outline previously given of the disturbing forces acting on a ship, it will be seen that the strain on the ends of the beams to destroy their connection with the side and loosen the fastenings, must be very great when the ship is under sail, either on a wind or before it—that is, either inclined or rolling. The principal action of these forces is to alter the vertical angle made by the beam and the ship's side—that is, to raise or depress the beam, and so alter the angle between it and the side of the ship above or below it. On the lee-side the weight of the weather side of the ship and all connected with it, and of the decks and everything upon it, as well as the upward pressure of the water, all tend to diminish the angle made by the beam and the ship's side below it, and consequently increase the angle made between them above it. The contrary effect is produced on the weather side, where the tendency is to close the angle above the beam and open that below it. If the beam when subjected to these strains, be considered as a lever, it will be evident that the fastenings to prevent its rising ought to be as far from the side as is consistent with the convenience or accommodation of the ship; and that while the support should also be extended inwards, the fastening to keep down the beam-end should be as close to the end of the beam, and consequently to the ship-side, as it can be placed.

Practical Building.

The annexed section of the side of a three-decked ship of the royal navy shows some of the modes that have been adopted for securing the ends of the beams.

Half-beams.

Beams which do not extend from one side of the ship to the other are called half-beams. They are introduced whenever the hatches or openings in the middle of the ship are such as to require the whole or unbroken beams to be so wide apart that the deck requires support between them. Their ends, towards the midships, are received by fore and aft pieces called carlings, which go from beam to beam; and any intermediate athwartship pieces between the carlings are called ledges.

Carlings and ledges.

Hooks.

The two sides of the ship at the bows are connected by hooks, which are either of timber or of iron. It is important to remember that the hooks above, and those below the surface of the water, are subjected to an opposite strain. The tendency of the pressure of the water on the bow is to make the sides collapse, and therefore the hooks below the water's surface should not only act as ties to the bow while the ship is grounded—as, for instance, when in dock—but should be formed more especially to resist the pressure of the water when she is afloat. Those hooks which are above the surface of the water act principally as ties, the rake of the bow and the weight of its parts tending to separate the two sides of the ship.

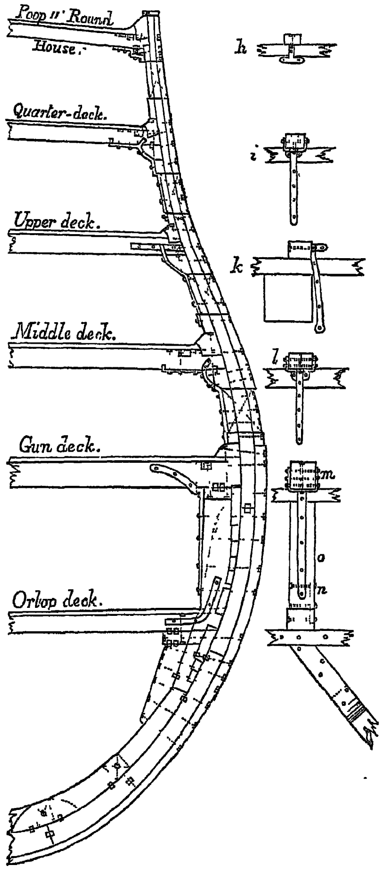

Fig. 33.

Planking.

The plank, or skin, or sheathing of a ship, both external and internal, is of various thicknesses. A strake of planking is a range of planks abutting against each other, and generally extending the whole length of the ship. A thick strake, or a combination of several thick strakes are worked wherever it is supposed that the frame requires particular support—for instance, internally over the heads and heels of the timbers; both externally and internally in men-of-war vessels between the ranges of ports; and internally to support the connection of the beams with the sides, and at the same time form a longitudinal tie. The upper strakes of plank, or assemblages of external planks, are called the sheer-strakes. The strakes between the several ranges of ports, beginning from under the upper-deck ports of a three-decked ship in the royal navy, are called the channel wale, the middle wale, and the main wale. The strake immediately above the main wale is called the black strake. The strakes below the main wale diminish from the thickness of the main wale to the thickness of the plank of the bottom, and are therefore called the diminishing strakes. The lowest strake of the plank of the bottom, and whose edge fits into the rabbet of the keel, is called the garboard strake.

Plank is either worked in parallel strakes, when it is called "straight edged," or in combination of two strakes, so that every alternate seam is parallel. There are two methods of working these combinations, one of which is called "anchor stock," and the other "top and butt." The difference will be best shown by the annexed figure. The difference in the intention is, that in the method of working two strakes anchor-stock fashion, the narrowest part of one strake always occurs opposite to the widest part of the

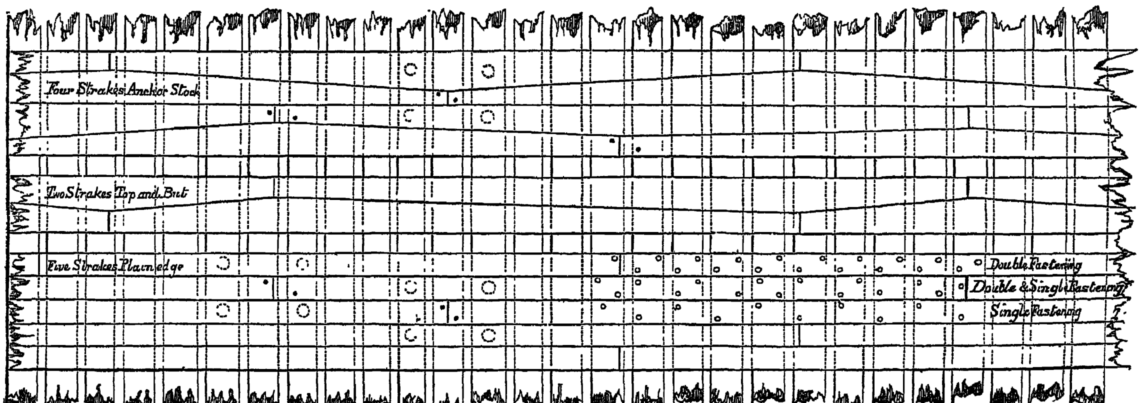

Fig. 34.

other strake, and consequently the least possible sudden interruption of longitudinal fibre, arising from the abutment, is obtained. This description, therefore, of planking is used where strength is especially desirable. In top and butt strakes the intention is, by having a wide end and a narrow end in each plank, to approximate to the growth of the tree, and to diminish the difficulty of procuring the plank. When the planking is looked upon as a longitudinal tie, the advantage of these edges being, as it were, imbedded into each other is apparent, all elongation by one edge sliding upon the other being thus prevented. The shift of plank is the manner of arranging the butts of the several strakes. In the ships of the royal navy the butts are not allowed to occur in the same vertical line, or on the same timber, without the intervention of three whole strakes between them.

Limber-strake.

Of the internal planking the lowest strake, or combination of strakes, in the hold, is called the limber-strake. A limber is a passage for water, of which there is one throughout the length of the ship, on each side of the keelson, in order that any leakage may find its way to the pumps.

Ceiling and internal planking.

The whole of the plank in the hold is called the ceiling. Those strakes which come over the heads and heels of the timbers are worked thicker than the general thickness of the ceiling, and are distinguished as the thick strakes over the several heads. The strakes under the ends of the beams

of the different decks in a man-of-war, and down to the ports of the deck below, if there be any ports, are called the clamps of the particular decks, to the beams of which they are the support, as the gun-deck clamps, the middle-deck clamps, &c. The strakes which work up to the sills of the ports of the several decks are called the spirketting of those decks—as gun-deck spirketting, upper-deck spirketting, &c.

Fastenings of the planks.

The fastening of the plank is either "single," by which is meant one fastening only in each strake, as it passes each timber or frame; or it may be "double," that is, with two fastenings into each frame which it crosses; or, again, the fastenings may be "double and single," meaning that the fastenings are double and single alternately in the frames as they cross them. The fastenings of planks consist generally either of nails or treenails, excepting at the butts, which are secured by bolts. Several other bolts ought to be driven in each shift of plank as additional security. Bolts which are required to pass through the timbers as securities to the shelf, water-way, knees, &c., should be taken advantage of to supply the place of the regular fastening of the plank, not only for the sake of economy, but also for the sake of avoiding unnecessarily wounding the timbers.

The planking in the royal yards is not usually fastened permanently till some time after it is trimmed and brought on to the bottom of a ship. It is thus allowed to season and shrink; and one strake in eight or ten is left out for the purpose of allowing ventilation, and to make good the shrinkage, and also to allow the strakes to be refayed. Without the latter provision there would be such an alteration of edge as would throw the holes made for the temporary securities out of the range of the strakes; but with this precaution it is very seldom that the alteration of edge is such as to require new holes, especially as the iron screw-eye bolts used for this temporary fastening are of much smaller diameter than the permanent treenail fastening, and therefore the holes for them through the plank can still be made good holes for the treenails. This method of securing the planks by a first or temporary fastening, to be afterwards substituted by a treenail, is also of advantage in enabling them to be brought into close contact with the timbers, in the saving of bolt fastenings, and in causing a good and regular seam to be given for the caulking.

The advantages and disadvantages of iron as a fastening for planking have been already discussed. The strength of treenails to resist a cross-sheering strain, as found by Mr Parsons, late of H.M. Dockyard Service, is shown in the following table:—

Experiments on fastenings.

"*Table of the Transverse Strength of Treenails of English Oak used as fastening for Planks of* 3 *and of* 6 *inches in thickness, and subjected to a Cross Strain.*

"In all these experiments on treenails, when the treenails were evidently good, they gave way gradually. In some of the rejected experiments, however, the treenails certainly did break off suddenly, but then they were evidently, on examination, either of bad or over-seasoned material. It has been asserted that the treenails made from the Sussex oak are much stronger than those made from the New Forest timber, or any other English oak. To ascertain the truth of this assertion, some experiments were made with Sussex and New Forest treenails of all sizes; and the result was, that there was not the least difference in them, the New Forest were, on experiment, quite as strong as the Sussex. In the experiments on treenails, the plank generally moved about half an inch previous to the fracture of the treenail."

The following useful tables were also drawn up by Mr Parsons from a series of valuable experiments carefully made by him, and show the longitudinal holding power of treenails. The first of these tables exhibits the adhesion of iron and copper bolts, driven into sound oak, with the usual drift, not clenched, and subject to a direct tensile strain. By drift is meant the allowance made to insure sufficient tightness in a fastening; it is therefore the quantity by which the diameter of a fastening exceeds the diameter of the hole bored for its reception.

"In Riga fir the adhesion was, on an average, about one-third of that in oak, and in good sound Canada elm it was about three-fourths of that in oak.

The following table exhibits the strength of clenches and of forelocks as securities to iron and copper bolts, driven six inches, without drift, into sound oak, either clenched or forelocked on rings, and subjected to a direct tensile strain. It gives the diameter of the bolt on which the experiment was made, as well as the number of the experiment:—

Practical Building.

" In the experiments on the clenches, the clenches always gave way; but with the forelocks it as frequently occurred that the forelock was cut off as that the bolt broke; and in the cases of the bolt breaking, it was invariably across the forelock hole. According to the tables, the security of a forelock is about half that of a clench.

" It appears an anomaly that the strength of a clench on copper should be equal to that of one on iron. But, in consequence of the greater ductility of copper, a better clench is formed on it than on iron. Generally the thickness of the fractured clench in the copper was double that in the iron. With rings of the usual width for the clenches, the wood will break away under the ring, and the ring be imbedded for two or more inches before the clench will give way.

" With the inch copper-bolts, all the rings under the clenches turned up into the shape of the frustum of a cone, and allowed the clench to slip through at the weights specified.

" Experiments with ring-bolts were made to ascertain the strength of the rings in comparison with the clenches. The rings were of the usual size, viz., the iron of the ring one-eighth inch less in diameter than that of the bolt. It was found that the rings always carried away the clenches, but that they were drawn into the form of a link with perfectly straight sides. The rings bore, before any change of form took place, not quite one-half the weight which tore off the clenches. It appears that the rings are well proportioned to the strength of the clenches."

From these tables it will be seen how much the strength of a clenched or fore-locked bolt falls short of the strength due to the full diameter of the bolt where a tensile strain only is applied to it; and when exposed to a cross strain, it is also well known how much the strength is diminished when the ends are not fastened and held securely in position. An increased use of screw-bolts with nuts and larger plates or rings under the heads and under the nuts would therefore give great additional strength; and if a sufficient length of the bolt were screwed at the end to allow of as much as an inch being cut off when too long, the supply of sizes necessary to be kept in store would not be large. Economy also would be likely to result from the greater accuracy in the length required to be given for the bolt about to be drawn from the store for use.

Practical Building.

Screw-treenails of the annexed form have lately been introduced by Messrs Hall, the well known builders of the Aberdeen clipper-ships, and whose modes of construction will be more particularly referred to hereafter. The increased holding power of such treenails to prevent planks from starting needs no demonstration.

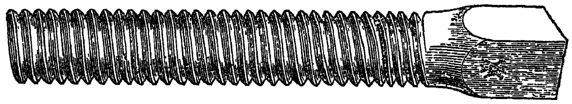

Fig. 35.

Decks.

The decks of a ship, as has before been stated, must not be considered merely as platforms, but must be regarded as performing an important part towards the general strength of the whole fabric. They are generally laid in a longitudinal direction only, and are then useful as a tie to resist extension, or as a strut to resist compression. The outer strakes of decks at the sides of the ship are generally hard wood, and of greater thickness than the deck itself; they are called the water-way planks, and are sometimes dowelled to the upper surface of each beam. Their rigidity and strength is of great importance, and great attention should be paid to them, and care taken that their scarphs are well secured by through bolts, and that there is a proper shift between their scarphs and the scarphs of the shelf.

When the decks are considered as a tie, the importance of keeping as many strakes as possible entire for the whole length of the ship must be evident; and it has already been stated that a continuous strake of wrought-iron plates beneath the decks is of great value in this respect. The straighter the deck, or the less the sheer or upward curvature at the ends that may be given to it, the less liable will it be to any alteration of length, and the stronger will it be. The ends of the different planks forming one strake are made to butt on one beam, and as the fastenings are then driven close to the ends, they do not possess much strength to resist being torn out. The shifts of the butts, therefore, of the different strakes require great attention, because the transference of the longitudinal strength of the deck from one plank to another is thus made by means of the fastenings to the beams, the strakes not being united to each other sideways.

Strain in caulking to be resisted.

These fastenings have also to withstand the strain during the process of caulking, which has a tendency to force the planks sideways from the seam; and as the edges of planks of hard wood will be less crushed or compressed than those of soft wood when acted on by the caulking-iron, the strain to open the seam between them to receive the caulking will be greater than with planks of softer wood, and will require more secure fastenings to resist it. It may also be remarked that the quantity of fastenings should increase with the thickness of the plank which is to be secured, for the set of the oakum in caulking will have the greater mechanical effect the thicker the edge.

Diagonally laid decks.

A deck, laid in a diagonal direction only, involves a great loss of strength longitudinally, and the advantages are not such as to compensate for this loss, and for the other inconveniences as to wear and tear, which result from such a system. Mackonochie proposed to lay decks in three layers, one diagonally from starboard to port, another from port to starboard, and an upper layer fore and aft. He also proposed a somewhat similar system for the outside planking, and vessels have been built on different modifications of this plan both in this country and in America.

Importance of securing the decks at the extremities.

At the two ends of a ship it is important that the strength of the tie of the deck should be maintained there, and while the continuation and connection of the shelf-pieces and waterway-planks are duly attended to, with any necessary hooks and crutches, additional strength to sustain the projecting bows and raking sterns may be obtained by a judicious connection of several beams to the extreme ends. This may be done by long bolts passed through the beams and secured by nuts and screws at their ends, or by pieces of timber fore and aft, underneath the beams, and bolted to them. These beams should have several ranges of carlings let down between them to diffuse the strain.

Dowelling and scoring down.

In all such connections of wood with wood, dowelling is much to be preferred to scoring down. The latter is objectionable on account of its wounding and weakening the parts in a greater degree, and the joint is subject to become loose or open by the shrinkage of the materials, and it also requires much more care and skill on the part of the workman for its perfect execution. It should therefore be discontinued wherever practicable.

Partners.

The frame-work of timbers which is formed round the mast-holes in each deck is called the mast partners. "Partners" generally are the principal timbers in a framing formed for the support of anything passing through a deck, as the masts and capstands.

Steps.

The pieces of timber to receive the heels of the several masts are called steps, as the main, fore, or mizen steps.

Coamings and head ledges.

Coamings are pieces generally faying on carlings, and rising higher than the flat of the deck, to form the fore and aft sides or boundaries of openings, such as hatch or ladder-ways; head ledges forming the athwartship boundaries to the same openings.

Caulking.

When the planks are fastened, the seams or the intervals between the edges of the strakes are filled with oakum, and this is beaten in or caulked with such care and force that the oakum, while undisburbed, is almost as hard as the plank itself. If the openings of the seam were of equal widths throughout their depth between the planks, it would be impossible to make the caulking sufficiently compact to resist the water. At the bottom edges of the seams the planks should be in contact throughout their length, and from this contact they should gradually open upwards, so that, at the outer edge of a plank 10 inches thick, the space should be about $\frac{10}{16}$th of an inch, that is, about $\frac{1}{16}$th of an inch open for every inch of thickness. It will hence be seen that if the edges of the planks are so prepared that when laid they fit closely for their whole thickness, the force required to compress the outer edge by driving the caulking-iron into the seams, to open them sufficiently, must be very great, and the fastenings of the planks must be such as to be able to resist it. Bad caulking is very injurious in every way, as leading to leakage and to the rotting of the planks themselves at their edges. It frequently happens, however, that the caulking is blamed when the leakage and the attendant evils have been caused by the edges of the planks sliding upon each other through the working of the deck or of the ship.

Marine glue.

Instead of pitch for closing the seams above the oakum, Mr Jeffery introduced a mixture of shellac and caoutchouc, combined with naphtha. This is at first more expensive, but its decided superiority and greater durability, preventing the necessity of so frequently re-caulking, will counterbalance this in due time, so as to be to the advantage of the ship-owner, though this will not make it economical to the ship-builder who builds and completes a vessel by contract. It is insoluble in water, and impervious to it; it is also elastic, and yet of sufficient solidity to fill up the joint and give strength; and it is also powerfully adhesive, so as to connect the planks together at their edges.

The mode of applying diagonal trussing to strengthen the side of a ship constructed in accordance with the foregoing outline, will next be considered.

Diagonal trussing.

In the system of building which was superseded by that termed the diagonal system, the whole of the interior surface of the frame was planked, and a second series of internal frames was worked upon this planking, agreeing in direction with the timbers of the ship. Riders were also introduced in various parts, but not diagonally, and those in the hold were no doubt necessary when it was the custom to "ground" ships on a beach for repair; a large quantity of timber was thus massed together, having the appearance of great strength; but, in fact, from its weight, injudicious combination, disposition and fastening, much of it was, if not injurious, at least useless. The idea of diagonal trussing was not an entire novelty at the time when Sir Robert Seppings introduced it as a system. There is evidence, in the representation of a vessel under repair in the fifteenth century, of some pieces of timber having been used diagonally in her construction, as also in some other isolated instances. The credit, however, of calling the attention of ship-builders to the principles on which the advantages of diagonal trussing depend, is entirely due to Sir Robert Seppings, and no ship is now ever built without the principle being brought into action in a greater or less degree.

He described his system in a paper communicated by him to the Royal Society, and which is printed in their *Transactions* for the year 1814. In that paper, after supposing the frames for a two-decked 74 gun-ship to be in place, and the spaces between the frames filled-in solid, he proceeds as follows:—

"In this state the diagonal timbers are introduced, intersecting the timbers of the frame at about the angle of 45°, and so disposed as that the direction in the fore is contrary to that in the after part of the ship, and their distance asunder from 6 to 7 feet or more; their upper ends abutting against the horizontal hoop or shelf-piece of the gun-deck beams, and the lower ends against the limber strakes, except in the midships, where they come against two pieces of timber placed on each side of the keelson (called additional keelsons), for the purpose of taking off the partial pressure of the main-mast, which always causes a sagging down of the keel, and sometimes to an alarming degree. These pieces of timber are nearly as square as the keelson, and fixed at such a distance from it that the main step may rest upon them. They may be of oak or pitch-pine, and as long as can be conveniently procured. Pieces of timber are next placed in a fore and aft direction over the joints of the frame-timbers, at the floor and first futtock-heads; their ends in close contact with, and coaked or dowelled to, the sides of the diagonal timbers. In this state the frame-work in the hold presents various compartments, each representing the figure of a rhomboid.

"A truss-timber is then introduced into each rhomboid, with an inclination opposite to that of the diagonal timbers, thereby dividing it into two parts. The truss-pieces so introduced into the rhomboid are to the diagonal frame what the key-stone is to the arch; for no weight or pressure on the fabric can alter its position in a longitudinal direction, till compression takes place at the abutments, and extension of the various ties.

"This arch-like property of the diagonal frame not only opposes an alteration of position in a longitudinal direction, but also resists external pressure on the bottom, either from grounding or any other cause, because no impression can be made in its figure in these directions without forcing the several parts of which it is composed into a shorter space."

The trussing here proposed for the hold of the ship was undoubtedly with the intention of introducing the principle of the inverted arch or dome; and it must be remembered, that the general form of the vessels to which Sir Robert

Practical Building.

Seppings was accustomed approached that of a hemisphere at their midship section, and was very different from the comparatively flat or plain surfaces now common. Any lower ranges of riders and trusses brought on the floors and first futtocks could have little effect in preventing arching beyond that which arises from the additional resistance they offer to deflexion by their rigidity. In men-of-war with several decks above the lower deck, the object aimed at seems to have been to obtain a firm base on which to ground a new and upper series of diagonal ties and struts. It will be evident from these remarks, that it is not considered that the bottom of a ship, if filled-in solid, and made as little compressible as possible by this means, and by the introduction of additional or sister keelsons, requires any great expenditure of material or labour, in order to adapt a system of diagonal trussing to it. The position for its most beneficial application is undoubtedly the sides of the vessel, but whether struts or ties be used, there must be a proper starting point for their ends. In wooden vessels of ordinary construction, this would, perhaps, be found to be in the sister keelson, nearest the wing, or in the thick strakes or riders brought on at the head and heels of the floors and first futtocks. The importance of these last in resisting any strain, if the ship takes the ground and rests on her bilge, is also evident; and it would therefore be advantageous to increase their strength with this view, even if there existed no other reason. Having determined a base or starting point for the lower ends of the diagonals, the next point to be attended to is to determine a strong line of work to which to attach their upper ends. Where intermediate decks occur the diagonals must either be carried past them in one continued line, or a new system be commenced and carried on from that line. In this case the strain on the parts may become such that the direction of the ties and struts may require to be changed. While diagonals are useful as a means of firmly connecting the adjacent pieces of timber, it must be remembered that this is a small portion of their value, and that full advantage will not be ensured from them without due consideration being given to keep up an unbroken system of sides and of diagonals, with their ends firmly united. It is immaterial whether parallelograms or triangles be used, if the last side of the one be always made the first side of the next. A triangle is a valuable form in structures of this kind, because it is a figure which admits of no alteration in its form; its angles are invariable as long as the sides remain the same, that is, as long as they are neither elongated nor shortened.

These principles are becoming more and more appreciated every day, and the strength of ships is consequently becoming much increased.

Diagonal trussing in Government vessels.

In the government service the diagonals, which extend over the surface of the side of the ship, are of iron-bars, varying according to the size of the ship, and also of wood. The annexed wood-cuts represent and show portions of the side of a two-decked ship, the diagonal riders of iron passing up between the ports (figs. 36 and 37). They commence under the thick strakes over the first and lower futtock-heads, and run up unbroken to the shelf of the upper-deck. On the turn of the bilge, where it is most rounding, and where the ship would rest if she took the ground, there is a system of wooden trusses introduced to stiffen the vessel at that spot, which has before been stated to be so desirable an object.

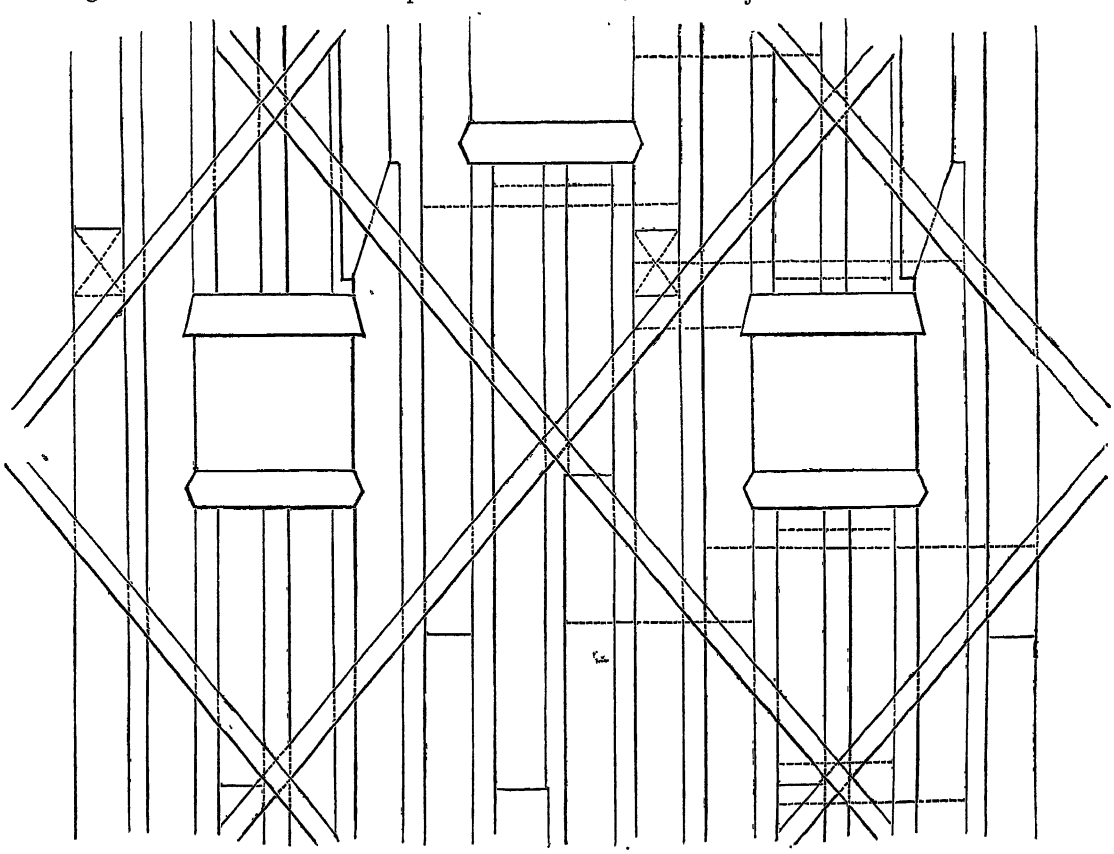

Fig. 36.

In other vessels the iron-bars are laid upon, and sunk into, the frames in one direction, while a series of wooden diagonal riders are placed upon the surface of the internal sheathing, crossing them in the other direction. In the fabric, as a whole, there appears a want, to the eye of an engineer, of a due consideration to the fact, that the strength of a box-girder, or tubular bridge, to which the mind naturally reverts as the simplest form of a long body to sustain

such weights and strains as those to which a ship is liable, lies mainly in the top and bottom, and not in individual portions of the sides. A lattice, or trellis girder, is nothing without the top and bottom bars uniting the lattice or trellis works. If a weight is to be supported by ties, there must be something to carry their upper ends without yielding; and if it is to be supported by struts, there must be a sound and unyielding foundation for them to rest upon, and from which they may rise.

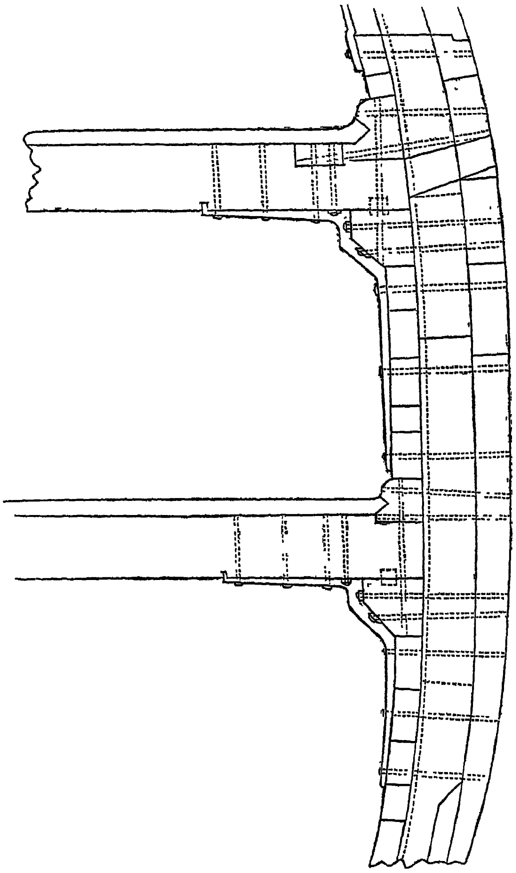

Fig. 37.

Details of ship Schomberg, by Messrs Hall and Co., of Aberdeen.

Messrs Hall and Co., of Aberdeen, carry out the principle to a great extent in the vessels built by them.

The following is a general description of the Schomberg (Plate III.), as built by them, in 1854, for James Baines and Co., of Liverpool, and many valuable hints may be gained from the practice of these eminent builders. She was expressly designed for an Australian passenger-ship, and every attention was paid to render her ventilation complete:—

Sheathing.

Her register measurement was 2400 tons; her frames were of British oak, $4\frac{1}{2}$ feet from centre to centre, close-jointed and bolted, and her sheathing consisted of four thicknesses of $2\frac{1}{2}$ inch Scotch larch, first two courses worked diagonally at an angle of 45° passing under the bottom of inside keel, and up the opposite side; the third course also passed under the keel, and was laid on transversely, same as the frames; there was a similar course worked inside between the frames, each course having a layer of felt, and a coat of Archangel tar, between them. The outside longitudinal planking averaged 6 inches in thickness, and the whole mass was combined by screw treenails of African oak, $1\frac{3}{8}$ inches diameter, put through the whole, there being one treenail at every foot in each strake of plank.

Beams.

She had three tiers of malleable iron-beams, there being one attached to each frame on each side of the three decks, as shown in the transverse section (Pl. III.) These beams were laid on pitch pine stringers, which were in two depths, and were attached to the sides by iron staple knees, a piece of plate-iron passing betwixt the beam end and the frame, and these plates being connected with the knees by the throat-bolts passing through them, and thus forming a lodgment for the iron beam ends. There was also a malleable iron-plate, $16 \times \frac{1}{2}$ inches, riveted to the top angle-irons on the beams; to this plate the water-ways were secured, besides being bolted horizontally. The sizes of the beams were:—

Upper deck,	$7\times\frac{1}{2}$ width,	$2\frac{1}{2}\times2\frac{1}{2}$	inches in single iron.
Middle deck,	$8\times\frac{1}{2}$	3	inches angle iron.
Lower deck,	do.	do.	do.

The beams were in one length; the lower edge with a bulb, and upper edge with angle-irons, back to back. They were supported by three tiers of iron stanchions, riveted to the beams, and bolted to the keelson and sister-keelsons.

For ventilation, the spaces, 3 feet wide, between the frames, were boarded up, and formed excellent ventilators from the various decks and hold, leading up to a space immediately under the main rail, which was fitted all round with venetians. She was also fitted with large funnels, and with a fanner for forcing the air down to the keel, besides scuttles on every six feet on the middle deck. The saloon was on the upper deck, and was fitted with a double roof for causing a current of air, with orifices all round under the cornice outside.

The vessel having a great rise of floor, it was levelled off inside to the 5 feet water-line, by having a fourth deck laid from end to end, and under this deck tanks were fitted to hold 300 tons of fresh water. Along the upper deck, from saloon forward, there was a range of houses for live stock, cook-house, and accommodation for the crew. This vessel sailed from Liverpool for Australia in 1854, drawing 21′ 6″ forward and 24′ 6″ aft, and on the eighty-fourth day was lost on Cape Otway, on a fine moonlight night. No favourable opportunity occurred during the passage to test her speed for any continued length of time; but she attained, on one occasion, a speed of sixteen knots for a few hours. This ship, complete, cost L.45,000.

The annexed figures are further illustrations of the details of construction adopted by the same builders.

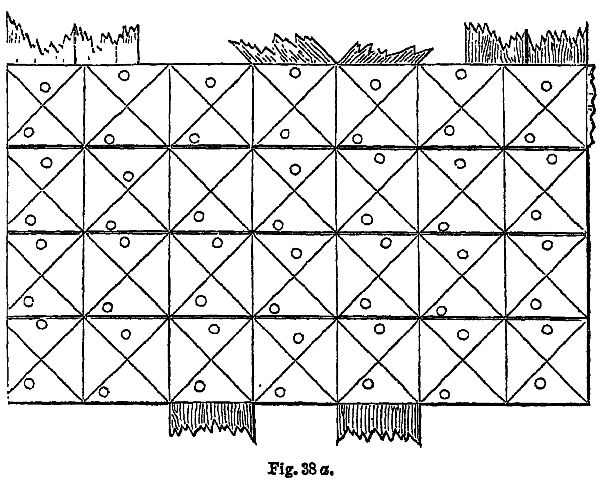

Fig. 38 *a*.

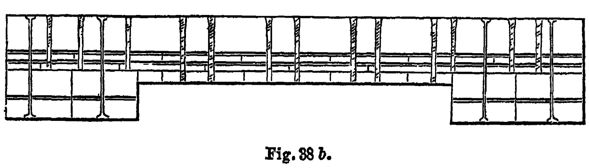

Fig. 38 *b*.

Practical Building.

Fig. 38 *a* represents an outside longitudinal section of the side planking fastened with screw-treenails; and fig. 38 *b* represents a vertical section of the same, with the felt between and the metal bolting in the frames.

Fig. 40 represents the mode of laying the diagonal planking of the deck under the longitudinal upper-deck planks.

Details of iron-ships.

A cursory view will now be taken of a few of the leading features in the construction of iron-ships, and of the mode of forming and uniting some of the principal parts; and the specifications, in full, to which two first-class steamships have been built, will then be given.

Keel.

The keel is sometimes formed of a single bar, with the floors crossing above it, and united to the floors by being riveted to the garboard strake. It is more frequently formed of a plate, sufficiently deep to form both the keel and the centre plate of the keelson, or of a box form. Specimens of these forms of keel will be found in the engravings. A box-keel may also be made thus (fig. 41):—

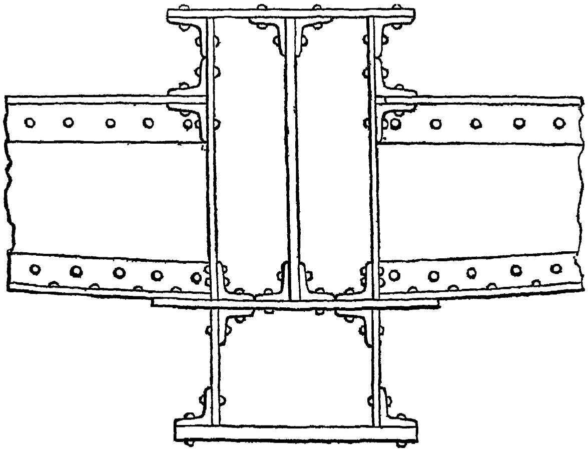

Fig. 41.

The points, in addition to general strength, which require attention, are, that if the keel be injured by the vessel taking the ground, it shall cause as little damage as possible to the vessel itself. A keel should also be capable of being varied in strength, so that it may be made stronger at the heel of the stern-post, where the bottom of the rudder is attached to it. It will be observed that this latter point is particularly attended to in the vessel for the Peninsular and Oriental Company.

In the keel, according to the sketch shown above, it will be observed that the plating is carried right across it, so that it might be very much injured, and probably even torn away in parts, without causing any leak into the ship, its edge being made purposely weaker than the bottom plate to which it is attached. Cross-plates with flanges, or with angle-iron, may be riveted across it, at any distance that may be desired, so as to stiffen it; and the plates can be made thicker, or additional strengthening plates may be added inside or outside the side-plates, at the stern-post, or at the forefoot.

Keelson.

The keelson is generally formed in one or other of the manners shown on the sections; and the floors may be carried across the bottom of the vessel, and the keelson be placed upon the top of the floors, following the same arrangement as in wooden vessels. In the latter case the side-plates of the keelson should be the whole depth of the floors, in addition to the height of the keelson above them, a space for each frame being cut out of the lower part of the plate to allow it to pass down between the frames, and be attached to the bottom by short pieces of angle-iron, as specified for the side keelsons of the Australasian, and shown in the section of that vessel at HH. There does not appear to be any particular advantage gained by the floor being made continuous across the bottom of the vessel; and as additional height is occupied by placing the keelson above them, there does not appear to be sufficient grounds for adopting this system in preference to the other.

Side or sister-keelsons.

With any side or sister-keelsons this is different, as it would be inconvenient to break the floors or frames again. In cases where such sister-keelsons are to be used as engine or boiler bearers, it would much improve their strength, and they would be better fitted to receive any such weights to be bedded upon them, if the plates were double, and they were brought up above the top of the floors, and formed into a box-keelson, thus (fig. 42). The

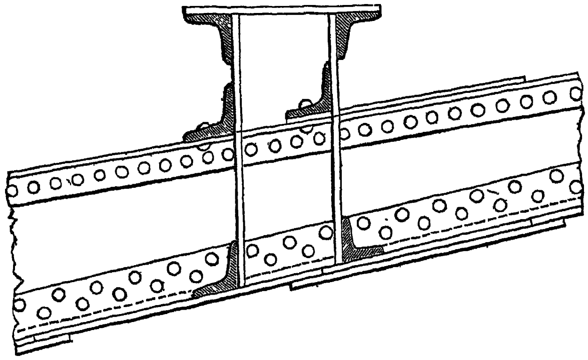

Fig. 42.

angle-irons of the keelson lying on the floors, and attached to them as they pass, stiffen them, and will tend to prevent their buckling or bending sideways when a great strain from the outside is brought upon them.

Where the floors abut on each side of the centre keelson, there is no reason why they should be the same height as the top of the keelson; and if the top or covering plate of the keelson be put on with external angle-iron (as shown in the above sketch) for a sister-keelson, great facilities are given for taking off the plate at any time for repair, or to renew any of the rivets. Indeed, there is no reason why different lengths of the covering plate should not be put on with screw-bolts, care being taken that the bolts fill the holes correctly.

Floors.

The floors are generally composed of an angle-iron, to which the external plating is attached, and a plate of any depth that may be desired, with single or double angle-iron on the inner edge of this plate. For the frames two angle-irons riveted back to back are generally sufficient. A T-shaped iron is also sometimes used, and if made with the centre web very deep, so as to be similar to the bulb-iron used for deck beams, it would be suitable for vessels of great strength, and, in some cases, for the floors with a single or double angle-iron on its inner edge.

Beams.

Some of the forms of beams have already been described. Beams formed of bulb-iron, with two angle-irons, are decidedly the most convenient, as there is no difficulty in welding them up in a common smith's fire to any length that may be required; and the top edge may be cut so as to vary the depth, and this even in the same beam if desired. By doing this the lower edge of the beam might be made straight, so as not to follow the round-up of the deck and of the upper edge; and thus any slight elongation of the beam, when brought down or straightened by any weight or strain, and the pressure to force out the sides of a ship consequent upon this, as dreaded by some, would be obviated.

The forms of bulb-iron, as generally rolled, do not give nearly so large a proportion of iron in the bulb as would be desirable. It is not consistent with the proper proportion of the flanches of beams, in reference to their depths, as laid down by Mr Fairbairn and other authorities on the subject.

Practical Building.

For beams 8, 12, 18, and 24 inches deep, proportions may be adopted according to the annexed four figures. The

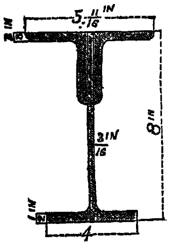

Fig. 43.

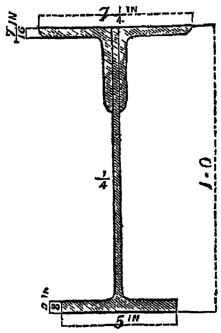

Fig. 44.

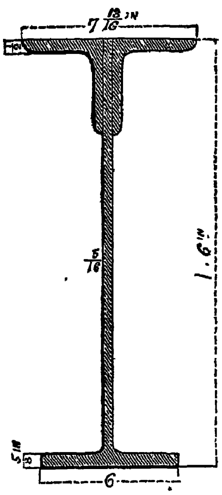

Fig. 45.

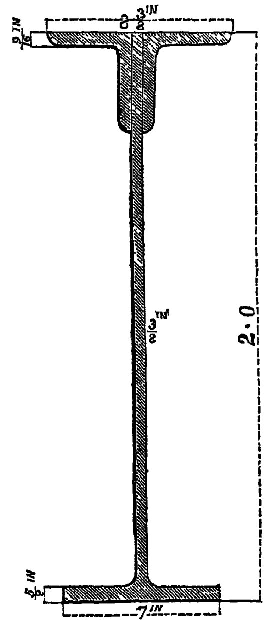

Fig. 46.

breaking weights of these beams, at the distances of 10 feet, 15 feet, 20 feet, and 30 feet between the supports, are respectively 10, 15½, 21, and 22 tons. The thickness of the webs may be considered by many to be too thin, but a beam of the annexed figure (fig. 47) is given by Mr Fairbairn as one much used by him, with a distance of 30 feet between the supports, and it may therefore be taken as a standard pattern. Where a saving of depth is a great object, the proportions may be varied. The relative strengths and weights of such beams, in comparison with ordinary wood beams, may be easily obtained by the rules which have been given.

Of the desirability of introducing iron-beams into wooden vessels there can be no doubt. Their durability alone ought to be a sufficient inducement.

Beams are now being welded up to any lengths by a process patented by Mr Bertram, late of Woolwich dockyard. The edges to be welded are brought together, and two jets of gas are made to play upon both sides at the same time till the iron is brought to a welding heat, when it is united in a most perfect and satisfactory manner.

Sheathing or plating.

An increase of thickness in the plates of iron-vessels adds to the safety and general strength of the vessel in a much more important degree than putting the additional weight into the frames to strengthen them. A large surface of unequal strength in different parts is objectionable; it will be sure to yield at the line where the weak and the strong parts meet, and probably a rupture may take place along that line; but if the surface be all of nearly equal strength, and a pressure be then applied, as may be the case on the exterior of a vessel, it may yield, and the indentation may be extensive without any rupture.

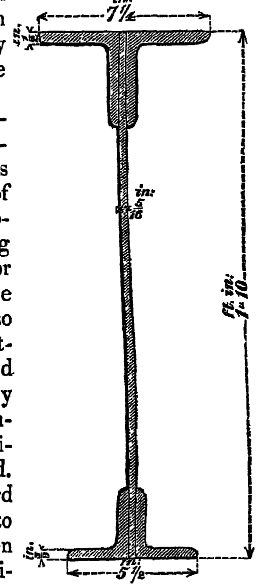

Fig. 47.

Riveting.

The subject of riveting has already been fully treated, when giving the details of Mr Fairbairn's experiments on the strength of riveted joints. Mr Bertram's process, as adapted for the welding of beams, and by which one or more experimental boilers have already been constructed, is also proposed for the purpose of uniting the plates of iron-ships, and there do not appear to be any reasons to prevent it from becoming available after more experience in its use has been obtained. The same remarks, with regard to decks, apply to iron-ships as to wooden ships; but iron has been more used as diagonal and longitudinal stringers under the deck-planks in the former than in the latter class of vessels.

In the accompanying sections of a vessel constructed to the design of Mr Bowman of London (fig. 48), the iron-plating below the deck-planks is shown, and it is laid complete over the whole surface beneath the deck-planks. The water-ways, or pieces for forming the run of the water at the sides to the scuppers, it will also be observed, are of iron, which is not usual, but it is an important improvement, and a step in the right direction of greater deck-strength. At the risk of its being considered a repetition, reference is again made here to the importance of this point, as the strength of an iron-vessel may be compared more easily than that of a wooden one, with the strength of iron tubular bridges. As has been before observed, the severest strain to which a vessel is likely to be exposed is when it is supported in the middle, and the two ends are left unsupported. As a familiar illustration of the mode of dealing with this subject, a vessel in this position may be looked upon as a beam supported at the middle, and weighted at the two ends, or, which is the same thing, as a beam pushed up in the middle and prevented from rising by the weights, or by being fixed at the two ends. And if this beam be now supposed to be turned upside down, or reversed, and then to be subjected to the same strains upon it as before, it becomes equivalent to a beam supported at the two ends and weighted at the middle, and all the calculations for beams or tubular bridges so weighted immediately become applicable. It will thus be seen that the bottom of the ship has to bear a strain of compression as due to the top, or top flanche of the tubular bridge, and the deck has to bear a strain of extension as due to the bottom or bottom flanche. The keel and keelsons, and the internal and external plates of the bottom, supported, or rather stiffened and kept in the direct line of the strain, by being attached at such short intervals to the floors, duly meet the case of the top flanche, and give the requisite strength; and the deck of the ship, and the strengthening pieces connected with it, must be made equal to meet the strain of extension, to which the bottom flanche of the beam is subjected. Let a vessel be supposed to be of the length of 300 feet, with a depth of 30 feet, and the weight of fittings, machinery, and everything which she has to carry to be 1500 tons, which may be assumed to be nearly correct for a passenger screw steam-ship of this length,—and let it be

Practical Building.

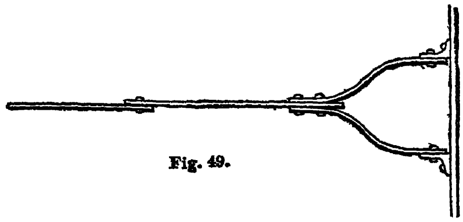

Fig. 49.

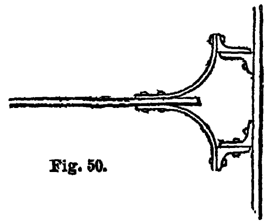

Fig. 50.

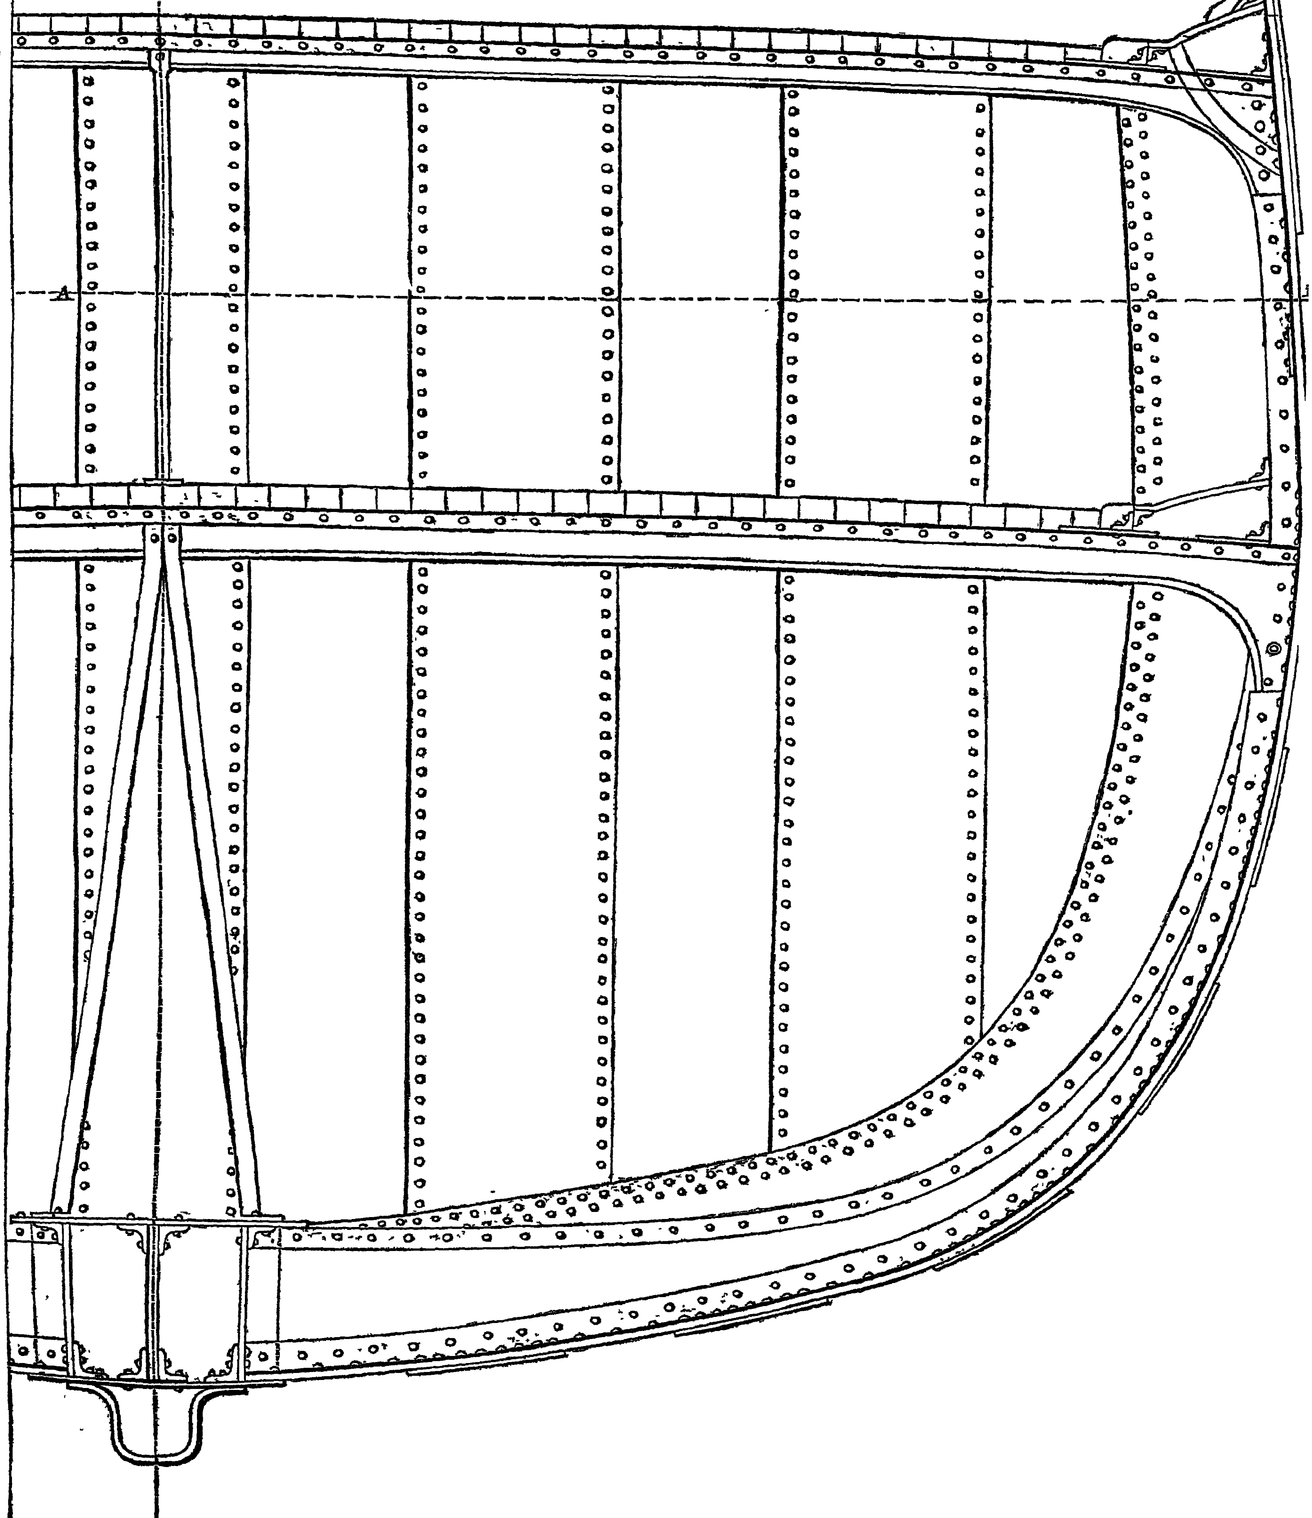

Fig. 48.

Practical Building.

further supposed that the weights are equally distributed over her length, then the strain would require to be the same as for a tubular bridge, or girder, to carry a weight of 750 tons at the middle. Now, if the ordinary rules be applied, it will be found that the sectional area of the bottom flanche of a box-girder of these dimensions, and whose breaking weight is 750 tons, would be 94 square inches; and doubling this for the excess of strength necessary in practice, will give an area of 188, or say 200 square inches of iron. The strength of the deck, therefore, at the middle, should be equal to the strength of iron-bars or plates of this sectional area, and towards the ends it may be diminished to about two-thirds of this strength, on the same principle and in the same manner as the flanches of a beam may be diminished.

An explanation of the theory of the strength of girders is not within the province of this article. It will be found very fully treated in the works of Tredgold, Hodgkinson, Barlow, Fairbairn, Latham and others, as also in some papers in the *Transactions* of the Institution of Civil Engineers, and in a paper in the *Transactions* of the Royal Society, by Mr Barlow, "On the position of the Neutral Axis."

Water-tight bulkheads.

While the advantages of iron water-tight bulkheads are unquestionable, nothing can be worse than that the sheathing should be weakened in one direct transverse line by a series of rivets, placed so close together as to lessen the strength of the plates in an undue degree at that line. The Board of Trade insist upon the bulkheads being attached to two frames, but it is not apparent how the difficulty is got over by this means alone, because on one or other of these frames the rivets must be sufficiently close to make the joint water-tight. This would be advantageous if the bulkhead were made to run home to the side of the ship, and be made water-tight there by an additional angle-iron, while the two frames on either side are united together through the bulkhead, so as to prevent the vessel separating along the line of weakness between them. In this view the inner line of plates uniting the frames to the bulkhead should be kept as close as possible to the ship's side, and therefore as much as possible in the direct line of the strain to be resisted.

The following is a specification of an iron screw-steamship for the Peninsular and Oriental Steam Navigation Company:—

Principal Dimensions.

Length between the perpendiculars	335 feet.
Length of the keel for tonnage	To be according to the approved design.
Breadth, extreme	39 feet.
Depth amidships (from top of keel)	31 „
Burthen in tons, Nos	2520. $\frac{8}{94}$ O. M.

Keel.—To be formed of plates, as shown in figs. 51 and 52, the centre through-piece to be 3 feet 6 inches deep from bottom of keel to top of floors, and $\frac{11}{16}$ thick right fore and aft. The plate on each side to be 10 inches deep by $1\frac{1}{2}$ inches thick. The fore and aft plate shown on top of floors to be $\frac{3}{4}$ in. thick, and 2 feet 6 inches wide, worked so as to fit on top of floors, and connected to centre through-piece by two angle-irons $4 \times 4 \times \frac{8}{16}$. The after-end of keel to have an angle-iron 6×4 on each side, and a plate $\frac{7}{8}$ in. thick on the bottom, to run for 50 feet from the aftermost stern-post.

Stem.—To be made of plate in exactly the same manner as the keel, the plate on each side the centre through-piece to gradually taper to $9\frac{1}{2}$ inches deep at the top, and all the bow-frames to be riveted to it.

Breast-hooks.—As may be required.

Stern-posts.—15 inches broad by 7 inches thick, and a heel left on the after-side to bear the rudder, with eyes for the pintles, and turned so as to form a knee forward on the keel. The screw-port to be forged in one piece to suit the drawing, or as the engineer may require.

Frames.—Of angle-iron, $5\frac{1}{2} \times 4 \times \frac{10}{16}$, and 20 inches from centre to centre. In engine and boiler spaces, the frames to be doubled in the bottom, and a reverse angle-iron on every frame, $4 \times 3 \times \frac{8}{16}$, from floor to gunwale, the whole length of the vessel.

Plates.—Garboard-strake, $\frac{17}{16}$ plates, as broad as can be procured, or worked; bottom-plates $\frac{13}{16}$, next plates up to the wales $\frac{12}{16}$, from the wales to gunwale $\frac{10}{16}$, except two plates, 2 feet 6 inches wide, $\frac{14}{16}$ thick, or one plate equal to this to form the wales; the sheer

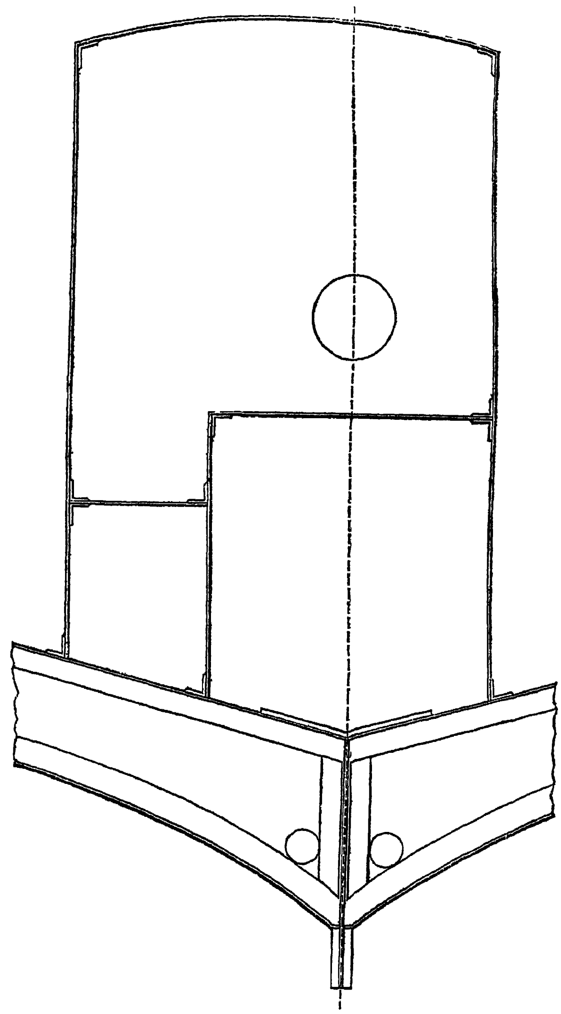

Fig 51.

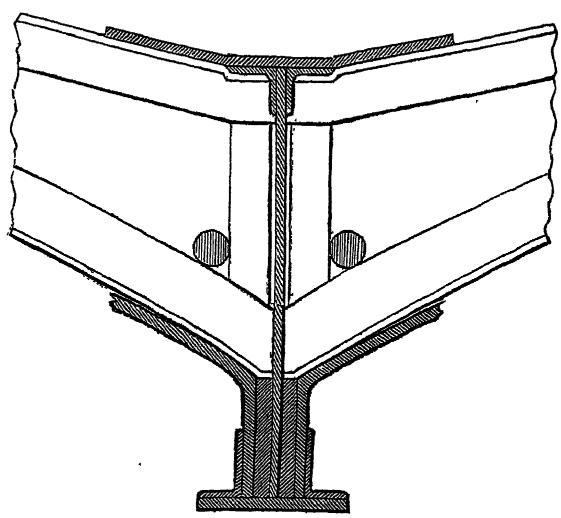

Fig. 52.

strake, $\frac{14}{16}$ thick, to be doubled right fore and aft, and butt-straps inside, as in single plates, all double riveted from keel to gunwale, and all butts to be flush; the upper or sheer-strake to go 12 inches above top of water-way, as per sketch. All spaces formed by the projections of the plates to be fitted with liners, so as to avoid small

Practical Building.

pieces and rings being used, except in the case of the sheer and upper wale-strakes, which will be doubled, and the inner strake will necessarily form the liner. The butts to be perfectly close as well as the seams, as no pieces will be allowed to be put in and caulked over. The counter-sinking to be carefully done and all rivets to be full and smooth outside plates, and to be chipped down while hot. The greatest care to be taken in the punching, to prevent unfair holes.

Floors.—30 inches deep in engine and boiler spaces of $\frac{12}{16}$ plates, with angle-iron, $4\frac{1}{2} \times 3 \times \frac{7}{16}$, on each side, on top of every floor, to run from 14 to 16 feet up the turn of bilge. The floors in after-hold, 30 inches deep, $\frac{10}{16}$ thick, with single angle-iron on top, $4\frac{1}{2} \times 3 \times \frac{7}{16}$. The floor-plates to run 6 feet up the turn of bilge on each side of frames in one piece.

Keelsons.—As may be required, and to suit the engineer's drawings, to run right fore and aft as far as the form of vessel will allow.

Pillars.—In holds between keelsons and beams, to be $3\frac{1}{2}$ inches in diameter amidships, tapering to $2\frac{1}{2}$ at the ends. One on every beam, or as may be directed. Pillars on main-deck, one on every other beam, arranged so as to suit the cabin plan.

Bulkheads.—Water-tight; one in fore-peak, two before the engine, one abaft the boilers, and one in after-hold; to be in accordance with the Board of Trade regulations in every respect. To have iron-bulkheads, or floors, on every frame from stern-post for 40 feet, and on every frame from stem for 20 feet, the after ones $\frac{5}{8}$ inch thick, the foremost $\frac{1}{2}$ inch. Those abaft the aftermost water-

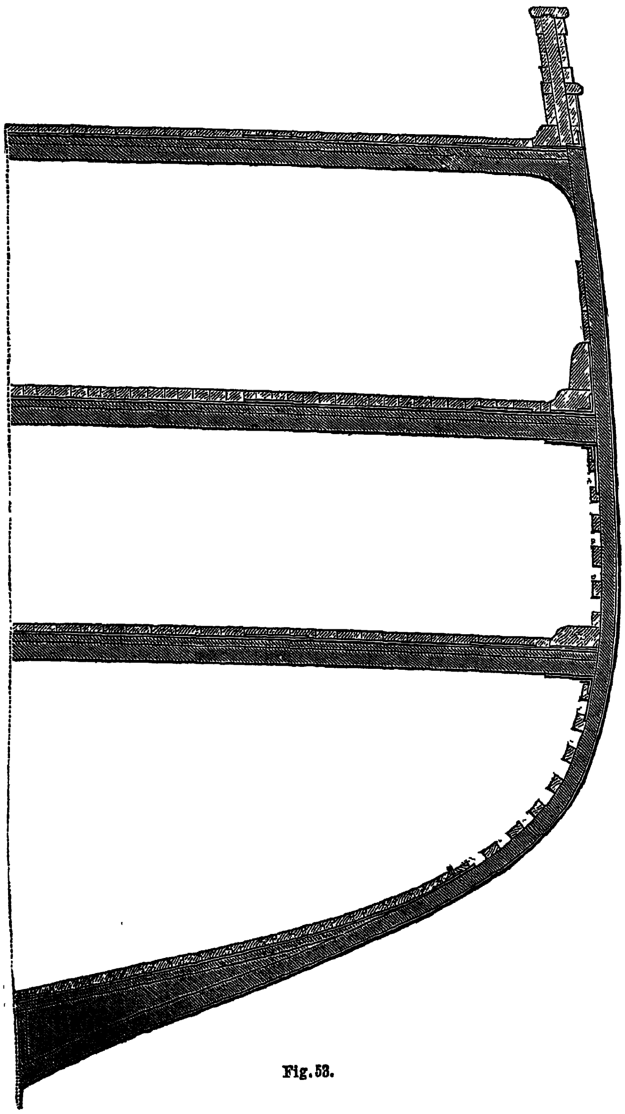

Fig. 53.

tight bulkhead to run up to the lower-deck water-way plate, and an angle-iron on the top of each, with a water-tight deck, riveted to the same. The lower-deck water-way plate will run through these bulkheads, as well as the water-way forming part of the deck. Proper man-holes, cut through each floor above the shaft, and sufficient water-tight man-hole doors, fitted to the holes in the iron-deck. The floors before the water-tight bulkhead to run up as far above the shaft as may be required. Every other bulkhead, the length of screw-shaft, to have a forged iron-rim, 3 inches wide, 1 inch thick, riveted round shaft-space. The hole for shaft to be drilled from after-end through all these by the engineers. All water-tight bulkheads to be fitted with approved brass sluice-valves. The space below the screw-shaft, abaft the aftermost water-tight bulkhead, to be filled-in solid with bricks and cement. Iron-tie bulkheads to be placed, as directed, between main and spar-decks, about 20 feet apart.

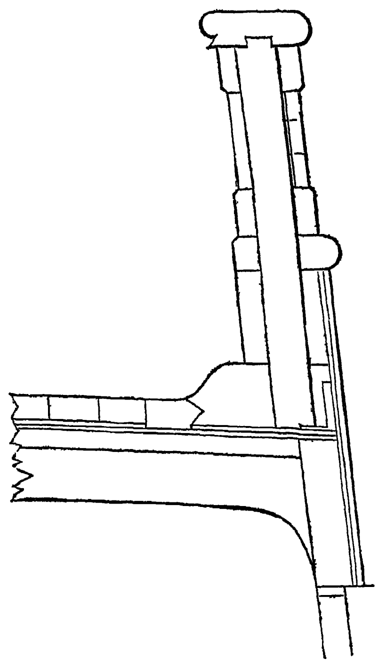

Fig. 54.

Beams.—Of plate, $10 \times \frac{7}{16}$, with two angle-irons on top, $3\frac{1}{2} \times 2\frac{1}{2} \times \frac{7}{16}$. Beams not to be turned at the ends, but to have a vertical and horizontal plate, riveted to under side of beams and side-frames, with an angle-iron in the angle, and to be finished on the lower edge, with half-round iron, as may be required. An angle-iron on each alternate frame, for main and lower decks, with as many in the engine and boiler spaces as the position of the machinery will allow. To have orlop-beams and a deck to allow of such accommodation for stores as may be required (fig. 53). Engine-beams as the engineers may direct. Eight of the foremost beams to be made of an elliptical shape, turned down 2 feet 6 inches to strengthen the bow, and likewise for the hawse-pipes to pass through. The plate to be twice the thickness of the other beams.

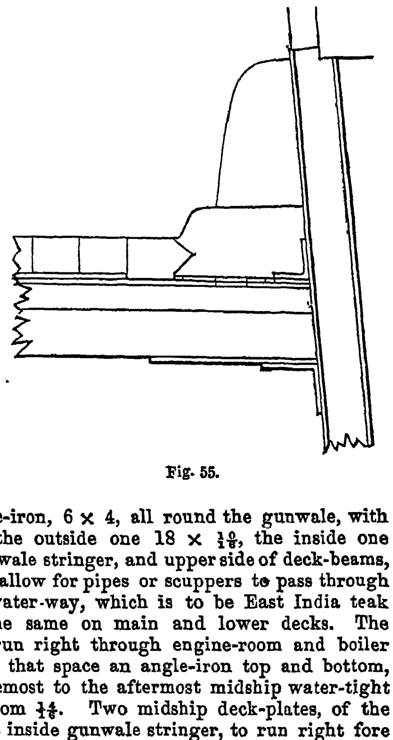

Fig. 55.

Stringers.—An angle-iron, 6×4, all round the gunwale, with two covering plates, the outside one $18 \times \frac{12}{16}$, the inside one $24 \times \frac{12}{16}$, riveted to gunwale stringer, and upper side of deck-beams, and 6 inches apart, to allow for pipes or scuppers to pass through the first plank from water-way, which is to be East India teak (figs. 54 and 55). The same on main and lower decks. The lower-deck plates to run right through engine-room and boiler space, and to have in that space an angle-iron top and bottom, and to be from the foremost to the aftermost midship water-tight bulkhead in engine-room $\frac{12}{16}$. Two midship deck-plates, of the same dimensions as the inside gunwale stringer, to run right fore and aft, full length of vessel, on each side of engine-room skylight, and riveted to upper side of deck-beams. To have at least 6 diagonal spar-deck plates, $12 \times \frac{1}{2}$, riveted on top of all these stringers, to tie the sides of the vessel together, to be placed as may be required (fig. 56). The butts of all these fore and aft stringers to be placed so that the whole of them come on beams, and to have a butt-strap to each butt 12 inches in width, and a row of rivets on each side of the edge of the beams. A vertical stringer, 2 feet 2 inches wide, $\frac{12}{16}$ thick, to run round the main-deck at back of spirketting, and to be connected to side deck-plate, or horizontal stringer, by

an angle-iron, $6 \times 4 \times \frac{10}{16}$. All these fore and aft stringers and deck-plates to run fore and aft, and not to be disconnected or cut through anywhere, and all water-tight bulkheads, beams, or any athwartship work to be cut round them, and all to terminate at each end in plate-breasthooks of $\frac{1}{8}$ in. thicker plate than the stringers, and to run out as far from either end as may be required. A bilge-stringer, formed of two angle-irons, $6 \times 4 \times \frac{10}{16}$, with a plate at back $18 \times \frac{9}{16}$, fastened to frames to run right fore and aft the ship. All stringers, vertical and horizontal, water-way plates, &c., to be doubled for 30 feet in way of cargo gangways.

Riveting.—The vessel to be all double riveted with $\frac{7}{8}$ rivets, except in keel and stern-post, which must be $\frac{1}{4}$th inch thicker than the plates they pass through.

Other Iron Work.—Iron casing round boiler space and stoke-hole, between main and upper-decks, likewise all coal-bunker bulk-heads (except what forms part of the engineer's contract). Coal-shoots and deck-plates for them, flat in bunker-bottoms, casing of bunkers, engine-beams, screw-tunnel, iron gratings over stoke-hole on upper deck, ash-bucket pipe from stoke-hole to spar-deck, with revolving cap on top, to be furnished by the contractors. A water-tight slide, at foremost end of screw-tunnel, to be fitted in accordance with the Board of Trade regulations. Preparation to be made for a lifting-screw on the most approved principles. The engineer to furnish all slides and lifting apparatus.

Topgallant Forecastle.—To be in accordance with the drawing given both in length and height, to be plated up from sheer-strake to top with $\frac{3}{8}$ iron-plates, and to be fitted up inside as may be directed. A manger, 3 feet deep, to be fitted forward, with 4 hawse-pipes, bucklers, plates, and all complete, as may be required by the company. The deck to be 3 inches thick, with iron-stancheons, and rails round the top-beams, $8 \times \frac{7}{16}$, bulb-iron, with 2 angle-irons on top, $3 \times 3 \times \frac{6}{16}$. A water-closet on each side, the aftermost end outside, with pumps, and all complete for the crew.

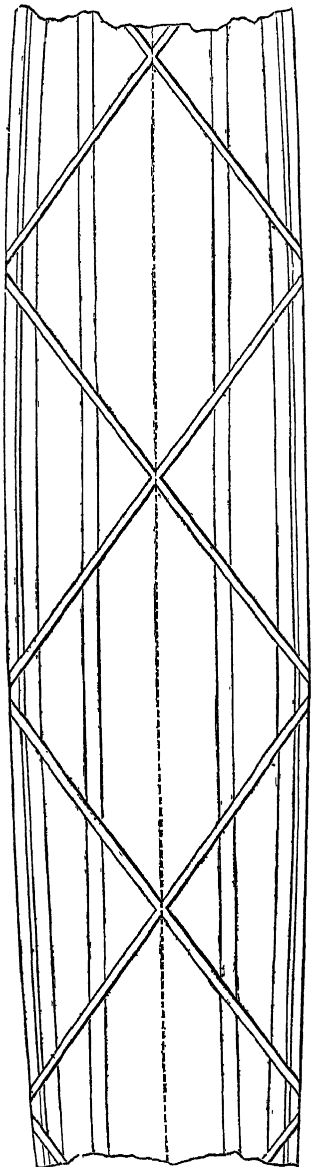

Fig. 56.

Inside Cement.—The vessel to be filled up solid to the limber-holes with Portland cement.

Quality of Iron.—Garboard-strake, sheer-strake, and longitudinal stringers, of Staffordshire B. B., of an approved maker, all the other plates of Staffordshire B., except curves, which are to be the best Lowmoor, or of iron made from best picked scrap equal to this.

Wood Work and General Outfit.

Upper or Spar Deck.—East India teak $3\frac{1}{4}$ inches thick, secured to beams by two $\frac{5}{8}$-inch galvanized iron bolts and nuts, let in $\frac{3}{4}$ths of an inch below the surface, and dowelled with wood. The mid-ship's deck-strakes to be 1 inch thicker, and to run fore and aft, or as may be required.

Main Deck.—Yellow pine 6×5, caulked and secured with iron bolts and nuts as upper deck.

Lower Deck.—Yellow pine $9 \times 3\frac{1}{2}$, caulked and secured with iron bolts and nuts as above.

Stancheons.—Teak or British oak 6×5. Stern timbers of the same 7×6, and to run well down, to give strength to the stern. All the other stancheons to run down on top of spar-deck, water-way plate through covering-board, and the space between under-side of covering-board, and top of water-way to be filled in solid and caulked, and a piece of teak-spirketting inside of stancheon, bolted through and through, from outside of iron sheer-strake, except in those stancheons which come in way of boats' davits, which will have an angle iron knee to turn under water-way, inside of bulwarks, well riveted to water-way plate. Oak or teak spirketting 18×9, to run right round the main-deck inside, on top of water-ways.

Awning Stancheons.—Of iron, all round the vessel.

Water-ways.—Upper or spar deck, and main deck, to be East India teak 18×9, and, if required, to be fitted over the angle-iron stancheons.

Ceiling of Hold.—Flat of floor laid with 3-inch American elm, and from that to be ceiled with yellow pine, room and space to the main deck beams. The remainder to be 2-inch close futline, caulked, payed, and beaded over seams, as will be pointed out.

Bulwarks.—Yellow pine $3 \times 2\frac{1}{2}$ thick, and to have a panel grooved in the centre.

Main-Rails.—Teak, $12 \times 4\frac{1}{2}$; to have copper or yellow metal along the edge outside, fore and aft.

Gangways.—To be where shown on plan—viz. four cargo-gang-way ports with all doors, brass scuttles, hanging platform to turn outside or inside as may be required, between main and upper decks, lined in sill and edges, with twenty ounces copper or yellow metal. Two passenger gangways on upper deck, fitted with the most approved accommodation-ladders complete, with all necessary fittings. Four coaling gangways on upper deck, fitted with doors complete; also hanging brackets riveted on ship's side, to carry stage when required. The ends of rough-tree-rail and gang-ways to be capped with a casting of brass.

Catheads.—British or African oak, 18×16, mounted with all stoppers, cleats, &c., as may be required.

Bitts.—Of British or African oak, 22×22, stepped on keelson. Towing bitts, topsail-sheet bitts, belaying pin-racks, cleats, eye-bolts, timber-heads, &c., to be fitted as and where required.

Bridge.—To be 5 feet 6 inches wide, to be supported with sufficient iron stancheons, and fitted with ladders, lamp-boxes, hand-rails, and all complete, as may be required.

Masts.—Lower mast and bowsprit of iron or steel as may be approved, and a provision to be made for cutting them away if required, the other masts and spars to be of black spruce or red pine, to be rigged according to plan.

Rigging.—Standing rigging of wire-rope, the rest of best hemp, with all requisite blocks. All blocks to be brass-bushed, or patent leather bushes, as may be preferred; all dead eyes, both upper and lower, to be made of lignum vitæ; if required the vessel to be fitted with Cunningham's patent self-reefing topsails.

Storm-House.—To be built at after-end of upper deck, with two two-berth cabins on each side of wheel, with a water-closet in each, and fitted up inside in every respect as first-class cabins. The top of this house, as well as those of all other cabins and offices on the upper deck, to be double; the upper one teak, the lower one pine, covered with canvass.

Companions and Skylights.—To be built according to plan. The tops of all of them on the upper deck to be made of East India teak.

Boats—To be in accordance with the Board of Trade regulations, and to be fitted complete, with masts, sails, oars, boat-hooks, breakers, gratings, davits for ship's sides, and all necessary fittings as may be required; brass rowlocks to mail-boat; life-boats to be according to Lamb and White's plan.

Fowl-Coops.—Twelve; 12 feet by 2 feet 4 inches high.

Sheep Pens.—To hold forty sheep.

Scuppers.—Eight on each side on each deck, to be placed where shown.

Fish-Davits.—For fishing anchors to be fitted, as will be shown.

Anchors and Chain Cables.—In proportion to tonnage of vessel, the anchors to be patent, or as required by the Board of Trade regulations.

Winches.—Two; if steam, the difference in price to be paid by the company.

Sails.—One suit of sails complete.

Tarpaulins.—One for each hatch and scuttle.

Awnings.—A complete set, fore and aft.

Pumps.—One copper chambered pump 8 inches in diameter, with brass bucket and lead pipe, fitted in every compartment, and a 7 inch and a 5-inch Downton, fitted as may be directed.

Wheels.—Two of mahogany, brass-mounted, hide-rope, fitted with patent steering gear complete.

Fenders.—With chains, &c., complete.

Ports.—Of East India teak, 21 inches square, with a 5-inch brass

scuttle fitted in the centre of each, hung with strong iron hinges, brass-bushed, and copper pins, except where shown round in plan, as in water-closets or other deck-offices, where scuttles must be fitted, 7 inches in diameter, of the best manufacture.

Water-Closets.—Tylor's of Newgate Street to be fitted where shown on plan, with cisterns, pipes, valves, and all necessary fittings.

Baths.—Hot, cold, and shower, to be fitted where shown on plan.

Tanks.—For 12,000 gallons of water, with all requisite cocks, pumps, pipes, and all necessary fittings.

Binnacles.—Two, with adjusted compasses and lamps complete.

Brass Bell.—18 inches in diameter, with vessel's name engraved thereon.

Cook-Houses.—Two of iron, with all necessary fittings complete.

Cooking and Baking Apparatus—With all necessary utensils complete, as may be required to be furnished by the company.

Colours.—A complete set as may be required.

Life-Buoys.—Six of such description as may be required.

Lanterns.—Signal-lanterns and fittings to be fitted where required—viz., 2 bridge, 1 mast-head.

Buckets.—Twelve wash-deck and twelve leather buckets, with the company's crest and ship's name painted thereon.

Hose.—Leather fire-hose and canvass-hose for washing decks, with the necessary couplings complete.

Capstans.—Two; the foremost, or main capstan, to be one of Brown's patent double-headed capstans, to work on top of topgallant forecastle, with all the bitts, stoppers, &c., fitted complete on spar-deck. The after one to be Brown's patent double-power capstan for warping the ship, and to be fitted complete.

Meat-Safe and Vegetable Locker.—One of each to be made and fitted, as will be shown.

Butcher's Shop.—To be where shown on plan, slate-tanks, and all complete.

Cabins.—To be fitted according to plans furnished by the company, arranged generally as the "Pera" and "Candia." The contractors to find everything complete, except saloon and fore-cabin tables, seats, chairs, sideboards, sofas, bed and sofa mattresses, curtains, camp-stools, glass, earthenware, plated goods and cutlery; cabin-lamps and looking-glasses; pantry, steward's and store-keeper's utensils; but the contractor will find all the furniture and fittings for all the cabins and offices in the ship, including first and second class passengers, officer's, engineer's, steward's, and any other cabin in the ship, such as chests of drawers, washstands with marble tops, tables, toilet-shelves, or any other fittings that may be required; likewise all the different offices on deck, as shown in plan, to be fitted complete, such as surgery, lamp-room, baker's shops, scullery, or any other office not named here, but shown on plan. All the cabins in the ship to be fitted with Robinson's patent ventilating bulkheads, as per elevation.

Painting.—All the wood-work to have four coats. The main-deck cabins, from the main hatch forward, to be grained oak in the very best style. The main saloon to have at least six coats of paint and two of best varnish, and the whole of the gilding to be of the very best quality.

Mail-Room.—To be where shown on plan. Space for sixty tons of mail, and to be lined with zinc all over. The bottom to have ledges of wood, $3 \times 2\frac{1}{2}$, 12 inches apart, secured to deck.

Sail-Room.—To be where shown on plan, and to be covered over with zinc.

Purser's Store-Rooms.—To be where shown on plan, and to be fitted up inside as may be directed.

Boatswain and Carpenter's Store.—To be where shown on plan, and to be fitted up as shall be directed.

Finally.—The whole of the material and workmanship to be of the very best quality, and the vessel (with the foregoing exceptions) to be entirely fitted and ready for sea at the cost of the contractors, notwithstanding any omission in this specification, and subject to the approval of the managing directors, or of such surveyor or surveyors as they may appoint to inspect the work.

The following is a copy of the specification of an iron screw-steamship, built for the European and Australian Royal Mail Company. The Australasian was built in 1857, by Messrs J. and G. Thompson, of Glasgow, under the inspection of Mr Bowman, of London, who has kindly permitted its publication here. The strength of this vessel, and the soundness of the principles on which she is constructed, were well proved by her grounding in the Clyde, on her first passing down the river after being launched, when she came off, as before stated, quite uninjured.

Specification of an Iron Screw-steamship to be built for the European and Australian Royal Mail Company.

Principal Dimensions.

	Ft.	In.
Length of keel	310	0
Breadth of beam	42	0
Depth of hold to spar-deck	29	9
To have three decks, with full poop and full topgallant-forecastle		
Height of poop	8	0
„ topgallant-forecastle	6	3
„ from main to spar-deck	8	6

Keel and Keelson.—The keel to be formed of three thicknesses of plate; the centre plate to be 1 inch thick, and 45 inches deep; forming, at same time, the main keelson and centre of keel; these plates to be in as long lengths as possible, to be put together, butt-jointed, with straps of same thickness, and double-riveted above that part which forms a portion of the keel; the plates to run the entire length of the vessel, and for 10 feet up the stem. The keel side-plates to be 12 inches $\times 1\frac{1}{8}$ inch; to be in as long lengths as can possibly be obtained; to be all scarphed on to each other, scarphs 6 inches long; these three thicknesses of plate, to be partially riveted together before the garboard-strake is fitted on; the garboard-strakes to be double-riveted to the keel with $1\frac{1}{4}$th inch rivets; all the holes to be runneled out perfectly true before riveting; the butt of the keel-plates and garboard-strakes to be carefully shifted and caulked, and made water-tight. (Section AB, fig. 59.)

Stern-post.—To be of best hammered scrap-iron in one piece, the after-post to be 12×5 inches, the inner-post to be 12×7 inches; the lower portion, uniting the two posts, to be 12×8 inches; and to have about 8 feet of keel attached to it, and with corresponding scarph for riveting to keel. The keel portion to be planed out into a groove, 1 inch wide and 6 inches deep, into which the keelson plate is to be worked, and double-riveted through and through. The end of the keelson-plate to be secured to the inner post by two vertical bars of angle-iron secured to it by rivets, and to the post by tapped bolts (fig. 57). The inner post, at the line of the lower

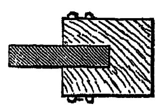

Fig. 57.

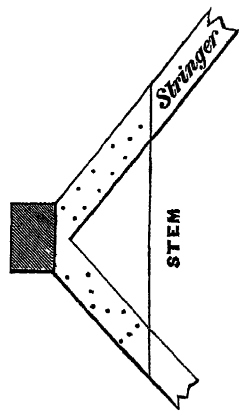

Fig. 58.

deck-stringer, to have a palm welded to it, which is to be firmly riveted to the stringer, so as to give security to the post (fig. 58). To be formed in the same way as the keel, from iron of the same dimensions, and riveted together in the same way; the keel, keelson, floors, stem, and stern-post to be according to sketch to be furnished.

Frames.—To be spaced throughout the vessel 18 inches apart from centre to centre, of angle-iron, $4 \times 3\frac{1}{2} \times \frac{5}{8}$th inch, to have a reverse angle-iron on every frame, $4\frac{1}{2} \times 3\frac{1}{2} \times \frac{1}{2}$ inch, riveted along the top of the floor-plates, and up the frames, to the height of the upper deck-beams, by $\frac{3}{4}$th inch rivets, 6 inches apart (every alternate frame from main-deck may be left without reverse iron, a piece being put in underneath the clamp-plate). Where desired, in wake of boilers and engines, the frames and reverse bars to be worked double.

Floors.—The floor-plates at keelson or amidships to be 33 inches deep $\times \frac{5}{8}$th inch thick; to be carried up past the turn of bilge, say to the 6 feet water-line, and riveted to the frames and reverse angle-irons. The end of each floor, which butts against the keelson, to have a vertical angle-iron, $5 \times 3 \times \frac{1}{2}$ inch, riveted to the floors and to the centre keelson, (section CD, fig. 59). Along each side of the top of keelson-plate there will be angle-iron $5 \times 5 \times \frac{5}{8}$ths. riveted on a level with the top edge of keelson-plate and floors. A

Practical Building.

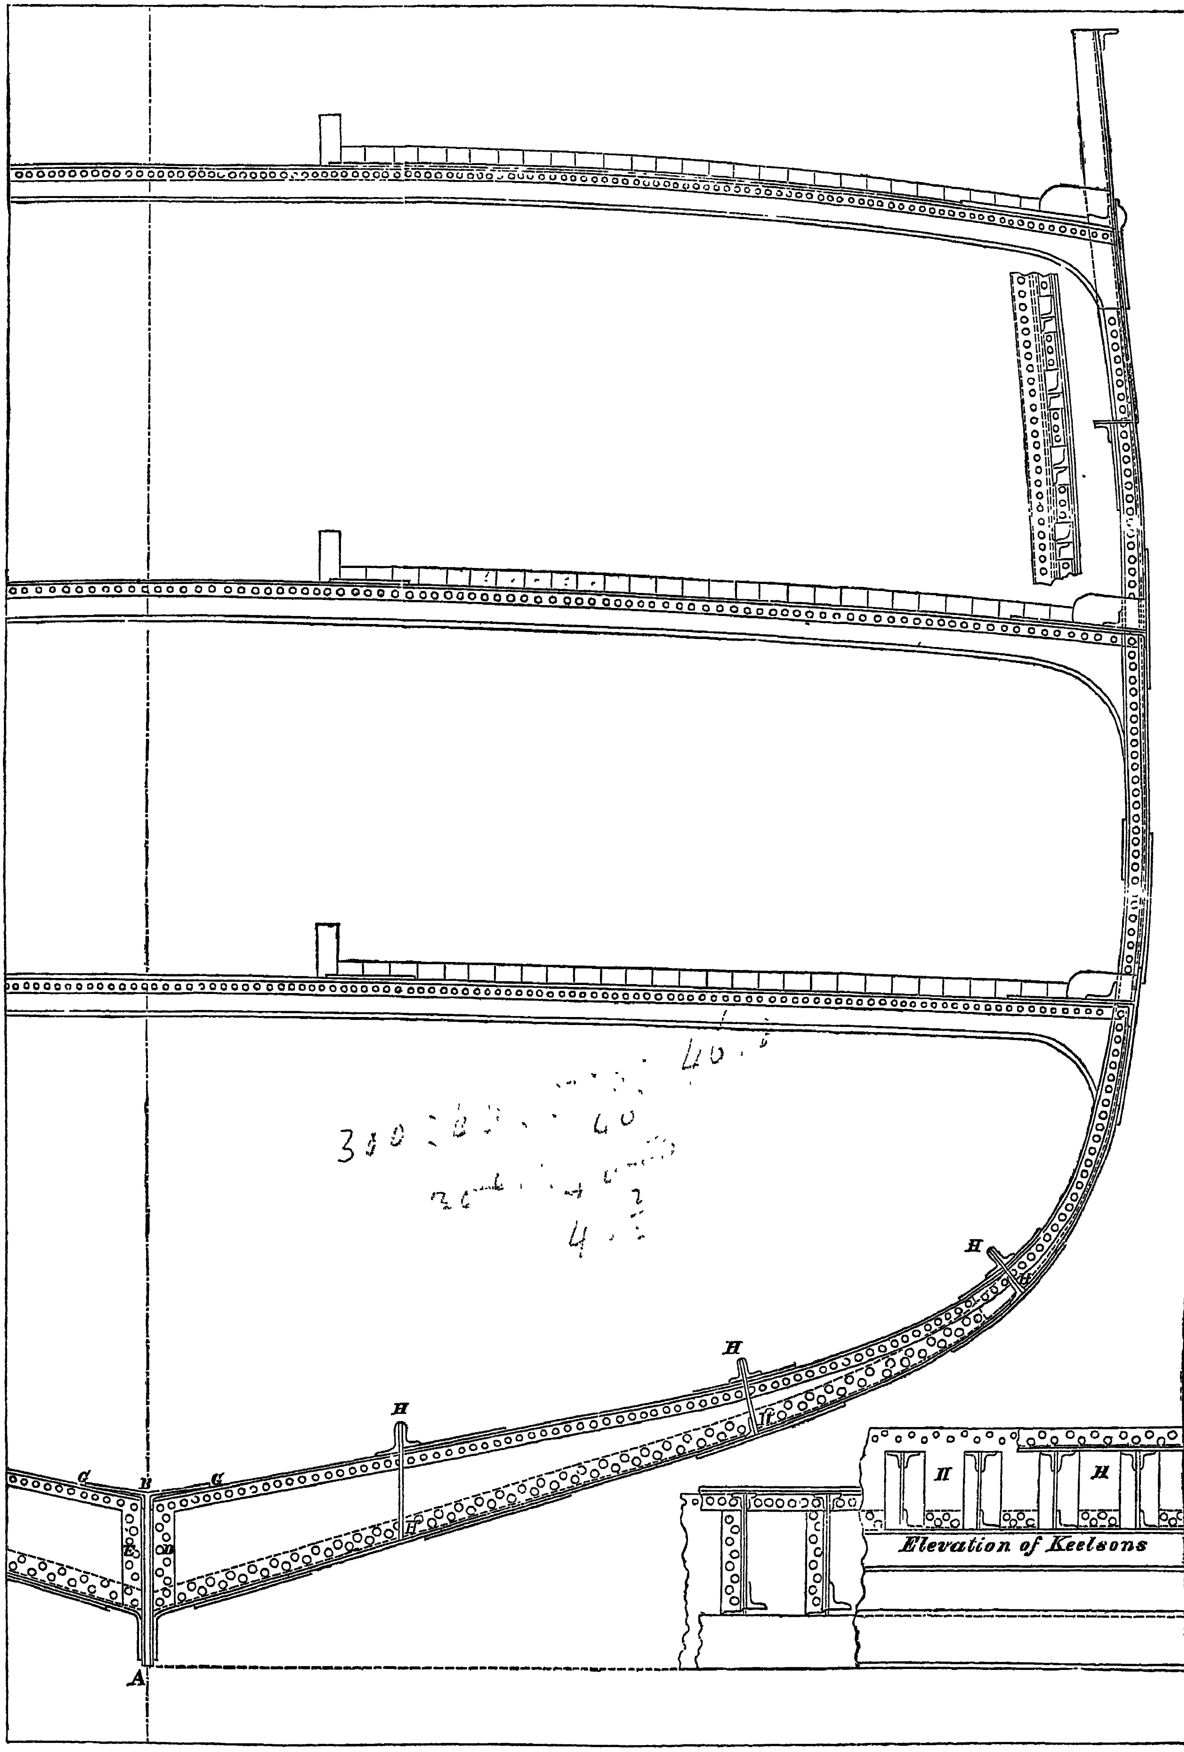

Fig. 59.

Practical Building.

plate 36 × $\frac{7}{8}$th inch in engine-room, and 36 × $\frac{13}{16}$ths at ends of vessel, in long lengths, will run the whole length of the vessel, and be riveted to the angle-iron on top of keelson, and to the reverse angle-irons of the floors; these plates to be built jointed, and double riveted, section GG.

Keelsons—To have two side and two bilge keelsons, to be formed of plates 30 inches broad × $\frac{5}{8}$th inch, riveted to the reverse frames. On the centre of these plates there will be double angle-iron 6 × $3\frac{1}{2}$ × $\frac{5}{8}$th, riveted back to back, and to the plates. From betwixt these angle-irons there will pass down to the skin-plate $\frac{5}{8}$th inch thick, the breadth regulated by the distance apart of the frames and reverse angle-irons; these plates to be riveted at the foot to short pieces of angle-iron, secured to the skin, and at the top, betwixt the floor angle-irons, section H. H., &c., &c.; to have intermediate keelsons for about 150 feet amidships, to be double angle-iron 6 × $3\frac{1}{2}$ × $\frac{5}{8}$th inch, riveted back to back, and to the reverse angle-irons on the floors, and to be connected to the outer skin, same as the other keelsons, section H. H. The whole of the stringers, main, bilge, and other keelsons, to pass unbroken through the bulkheads, and to be made water-tight by strong brackets, riveted to them, and to the bulkheads.

	Fd.	200 feet Mid.	Aft.
Plating.—Garboard-strake to be fitted close up to the frames.........	$\frac{7}{8}$	1 in.	1 in.
Next strake to garboard (to garboard).....................................	$\frac{3}{4}$	$\frac{7}{8}$	$\frac{7}{8}$
Thence to bilge....	$\frac{11}{16}$	$\frac{3}{4}$	$\frac{11}{16}$
Bilge-strake..............................	$\frac{11}{16}$	$\frac{3}{4}$	$\frac{11}{16}$
Thence to wales..........................	$\frac{9}{16}$	$\frac{5}{8}$ & $\frac{9}{16}$	$\frac{1}{2}$
Wales in two strakes.................	$\frac{7}{8}$	$\frac{7}{8}$	$\frac{7}{8}$
Thence to sheer-strake...............	$\frac{7}{16}$	$\frac{1}{2}$	$\frac{7}{16}$
Sheer-strake at least 36 in. broad	$\frac{7}{8}$	1	$\frac{7}{8}$

The plating from keel to gunwale to be lap-jointed horizontally with vertical flush-butts, with an internal strap of corresponding thickness to the respective plates, 8 inches wide. The butt-straps of the sheer, wale, or garboard-strakes to be cut across the thread of the iron from plates, and to be $\frac{1}{16}$th thicker than the plates to which they are respectively fitted. All the plates which end on screw-frames, and the next adjoining them on every strake, to be not less than $\frac{13}{16}$ths thick, and double riveted, with very great care, to the stern-frame.

Riveting—The keel, stem, stern-post, and all the longitudinal seams of the plates, up to the spar-deck, to be double riveted. All the butts throughout the ship to be double riveted. Double riveting to have about eight rivets to the foot. The bar-rivets, through frames and plates, to be spaced 6 inches apart, and the plating to be wrought out and in fashion; the space between each alternate strake, and the frame being filled with a solid sliver-piece closely fitted; all the rivets of keel, stem, and stern-post, to be $1\frac{1}{4}$th inch diameter; those passing through inch plates to be 1 inch; through $\frac{7}{8}$th plates, to be $\frac{13}{16}$ths; through $\frac{3}{4}$th plates, $\frac{7}{8}$th inch; remainder, $\frac{3}{4}$th inch.

Caulking.—The whole of the seams and butts to be caulked in the most careful manner, and made perfectly water-tight; and on no account is any canvass, or red-lead, or like substance, to be inserted in the seams, but all to be caulked throughout, metal to metal.

Beams.—Main-deck beams, of patent bulb-iron, 10 × $\frac{5}{8}$th inch; upper and lower deck-beams, of patent bulb-iron, 9 × $\frac{1}{2}$ inch, all to be spaced on alternate frames; the upper, main, and lower deck-beams to have double, 3 × 3 × $\frac{1}{2}$ inch angle-iron, securely riveted on top edge, with rivets 8 inches apart; all the beams to have suitable knees, solid, 18 inches deep, for securing them to the frames, formed by bending round the ends of the beams.

Stringers.—On the upper-deck, of plate, 42 × $\frac{5}{8}$ths amidships, and $\frac{9}{16}$ths at end, with angle-iron 8 × $3\frac{1}{2}$ × $\frac{5}{8}$th inch riveted to it, and to the deck-beams, and double riveted to the sheer-strake on the main and lower deck, of plate 36 × $\frac{5}{8}$ths amidships, and $\frac{7}{16}$ths at end with angle-iron, 5 × 3 × $\frac{5}{8}$th inch, firmly riveted to the main and lower deck-beams, and reversed angle-irons, 2 feet below the main and upper deck-beams, to have a clamp-plate 18 × $\frac{5}{8}$th inch, running the whole length of the vessel, and securely riveted to the reverse angle-irons on the frames, by rivets spaced 4 inches apart. All the butts to be double riveted.

Deck Trussing.—On the upper and main deck, on each side of the hatches, to have a plate $24\frac{1}{2}$ inches, carried right fore and aft, worked in lengths of 15 feet, with double-riveted butts, the whole riveted to the beam angle-irons with ten rivets in each; the whole space from the outside edge of this to the inside edge of gunwale stringer on the upper-deck to be filled in with plate, wrought in long lengths, not less than 18 inches broad and a $\frac{1}{2}$-inch thick (these plates may be $\frac{3}{8}$-inch, and cover a space equal in weight to those plates specified).

All butt-jointed longitudinal straps single riveted, thwart straps double riveted; the whole riveted to the beam angle-irons with rivets spaced 4 inches apart.

Practical Building.

Hold Stancheons.—From keelson to lower deck beams to have $3\frac{1}{2}$ inches round iron stancheons, riveted securely to the keelson-plate and the beams; above these from lower deck to main deck to have 3 inches round iron stancheons, firmly secured to both tiers of beams where necessary

Bulkheads.—To have the number of water-tight bulkheads that may be required by the company, fitted between double frames and over keelson and stringers, supported by suitable bars of angle-iron 4 × 3 × $\frac{1}{2}$, spaced 30 inches apart.

Bulkheads to be carried to main deck, and to be fitted in every respect in accordance with the Board of Trade regulations. Between the aftermost bulkhead, to which screw-propeller pipe is attached, and the stern-post, to have fitted on every frame, up to the height of lower-deck beams, a series of bulkheads formed of $\frac{1}{2}$-inch plate, and firmly riveted to the frames, and secured on the top with double angle-iron; at this line breast-hooks, specified afterwards, are to be worked forwards to the pipe bulkhead, so as to form an iron deck above these bulkheads specified, and to be riveted to the double angle-iron on them. The hole for passing stern-pipe through to be carefully arranged, so that no more than necessary space is cut.

Rudder.—The stock to be $7\frac{1}{2}$ inches diameter, with turned pintles, of best hammered scrap-iron, in one piece with the frames, and plated with $\frac{5}{8}$ths plate.

Breasthooks and Crutches.—To be fitted at each deck, fore and aft the ship, at the junction of the stringer plates; bilge and side keelson formed by riveting triangular plates about 9 feet long to these fore and aft ties, so as to firmly unite the two sides of the ship.

Mast-Partners.—On the various decks to be formed of materials similar to the beams, and to be securely riveted to them.

Gunwale Moulding.—To be formed of 6-inch half-round iron in length, securely riveted to the upper edge of wale strake by rivets about 8 inches apart.

Water-ways.—On main and lower deck of red pine $4\frac{1}{2}$ inches thick, and on the upper deck of East India teak 18 inches broad by 9 inches thick, both securely bolted to the stringer plates by two rows of bolts and nuts.

Decks.—To have three decks. Upper deck throughout where exposed to be of best East India teak $3\frac{1}{2}$ inches thick, to be secured to the beams by bolts and nuts at every third beam, and with a wood screw of best form on both sides of the alternate beams, the whole to be planed true on the edges, top, and bottom before being laid, and thoroughly caulked and payed with resin or pitch, as may be directed by the company, and made perfectly water-tight; main-deck to be of best seasoned Quebec yellow pine $3\frac{1}{2}$ inches thick, thoroughly secured to the beams by wood screws with bolts in the butts, thoroughly caulked, payed and made water-tight; lower-deck of 3 inches yellow pine to be similarly fitted.

Rails.—The rails to be of best East India teak of suitable breadth, firmly bolted to stancheons, to be covered on the outside and inside edge with 18 oz. yellow metal, firmly nailed; to have a netting all round of best cordage, firmly secured to galvanised iron rods on rail and water-way.

Bulwark Stancheons.—To be of East India teak, and to be fitted into sockets formed of angle-iron, 7 × 3 × $\frac{1}{2}$; these to be riveted to the stringer plates at proper intervals for the stancheons, one bolt through each socket and stancheon.

Hatch Coamings.—On main, upper, and lower decks, of East India teak, of dimensions to suit the size of the hatches, and securely bolted to the iron carlines; to be protected by iron plates on sides and top, and fitted with iron battens, cleats, and cutbands; on upper decks to have teak skylights on the hatches.

Ceiling.—In flat of floor in holds of $2\frac{1}{2}$-inch elm, thence to hold beams of 2-inch red pine from hold beams to main-deck beams, and cabins and store-rooms of 1-inch yellow pine close seamed; the ceilings to be bolted to reverse angle-irons with galvanised screw-bolts.

Ports.—To have four gun-ports on each side, with flaps properly arranged in netting, and fitted with ring-and-eye bolts as required.

Capstands.—To have one of Brown's patent capstands of suitable size, placed forward, with patent chain-stoppers, and four riding bitts complete for working cable; in addition, to have a cast-iron working capstand, with brass top on quarter-deck poop, both complete, with all necessary bars.

Catheads.—Of British oak, with anchor stoppers, and all usual fittings.

Bitts.—To have at least five cast-iron mooring timber-heads on each side, of suitable strength, properly bolted through water-ways and stringer plates, with heavy chocks of hard wood timber below.

Hawse-pipes.—To have a strong cast-iron hawse-pipe on each bow,

of size to suit chains, firmly secured to the skin of the ship; also stern and side mooring pipes of cast-iron where required, and firmly secured.

Chain-Lockers.—To be built of wood where required.

Anchors and Chains.—To have anchors and chains; the chain cables of best best iron, and to be tested to the government test. Hemp-warps according to Lloyd's rules.

Anchor-Davits.—To have two strong anchor-davits, with blocks and falls complete for lifting anchors.

Pumps.—To have a pair of 6-inch Redpath's patent pumps in each compartment, with lead-pipes and roses, and all the necessary iron gearing for working.

Scuppers.—To have sufficient lead scuppers on upper and main deck, well secured to ship's side and water-ways.

Tanks.—To have suitable iron tanks made of quarter plates, capable of containing 10,000 gallons of water, with two fixed copper pumps with brass boxes, lead pipes, and iron gearing complete for working, and placed where required.

Masts and Spars.—To be rigged as a ship, with one complete set of masts and spars according to plan; lower masts and bowsprit of yellow, red, or pitch pine in one stick, or built and hooped if necessary; topmasts, lower and topsail yards, and jibboom to be of red or pitch pine, the remainder of black spruce; to be all according to plan, and complete with all usual iron work of best quality.

Rigging.—All the standing rigging to be of galvanised wire, the running rigging to be of the best St Petersburg or Manilla hemp and chain where required, chain of best best iron.

Blocks.—To have a complete set of iron and rope stropped blocks of suitable sizes, the lower and topsail yards brace blocks, topsail peak and throat haulyards, catblocks, &c.; to have Dalton's patent roller bushes in the sheaves, the standing rigging to be set upon lignum vitæ dead eyes of proper size; to have all necessary snatchblocks, catblocks, watch-tackles, and belaying-pins of greenheart.

Sails.—To have one complete suit of sails, the topsails to be fitted with Cunningham's patent reefing apparatus according to plan, of Gonvock extra canvass, with suitable Nos. complete, ready for bending with sail covers as required.

Iron Work.—All the small iron work of the hull to be furnished complete of the best quality.

Boats.—To have at least six boats, according to Act of Parliament, complete with strong iron davits, tackle falls, &c., as usual. The boats to be supplied with ash oars, rudders, tillers, and boathooks, and the four largest to have masts and sails.

All the boats to be supplied with canvass covers and gripes as required; the four midship boats to be carried inboard on beams of proper strength, and properly supported on iron stancheons from the rail, and to be fitted with patent lowering apparatus to a plan to be furnished.

Gangways.—To have properly-fitted gangways opposite to each hatch for receiving cargo; to have on each side a passenger-gangway, with suitable accommodation-ladders, davits for lifting, iron railings, and man-ropes.

Coaling-Ports.—To have fitted along ship's side, between upper and main decks, the number of coaling-ports that may be afterwards found necessary, properly hinged, so as to be perfectly water-tight when closed, and fitted with strong iron shoots inside, communicating, by grated openings, with the upper-decks and with coal-boxes.

Painting.—The outside of the ship to receive three coats of the best oil paint, the inside two coats, except the bottom, which is to be coated with patent cement. The woodwork on deck to receive three coats, and to be grained in imitation oak. Masts and spars to receive two coats of paint or varnish. Cabins and internal fittings to be painted in the best manner, as may be afterwards directed.

Winches.—To have three double-power cargo winches, with derricks and chains complete, for working cargo.

Side Lights.—To have two brass side lights in each state-room on main-deck and spar-deck, all securely riveted to ship's side, and made water-tight.

Bells.—To have a ship's bell and belfry, with name engraved on it, and binnacle-bell.

Binnacles.—To have two brass and one mahogany binnacle, with lamps.

Figurehead.—To have a handsome full-length figurehead, with trail-boards, stern and quarter carving, as may be required to suit name, all handsomely relieved with gilding.

Flags.—To have one ensign, one burgee, one union-jack, one blue-peter, one private signal, and one set of Marryatt's signals with chest and book.

Signal Lanterns.—To have complete set of Admiralty signal lanterns (brass, of large size).

Guns.—To have two brass 4-pounder, and four iron 9-pounder guns, with breechings, rammers, and sponge complete, with all the usual complement of muskets, pistols, and cutlasses.

Steering Apparatus.—To have a handsome double-steering wheel of E. I. teak, fitted with right and left handed screw-steering gear, brass nuts, malleable iron crosshead, connecting-rods, and screw. To have two portable tillers fitted to rudder-stock; wheel to be covered by a substantial house, with glass front.

Cook-House.—To have a spacious galley of iron fitted on main or spar-deck, near funnel, with the most improved form of cooking apparatus and baking ovens for crew and passengers; the woodwork of the galley to be lined with 5lb. lead and felt, and the floor to be covered with fire-tiles, and to have proper ventilators on sides and top.

Poop.—To have a poop to extend from after-part of vessel to after-part of after-hatch, about 90 feet long; in forming the poop, every alternate frame of the vessel to be carried up, to which are to be joined the beams of the poop, same size of iron as the frames. The sides and after-end of the poop to be rounded over and plated with $\frac{3}{8}$ plates, the poop-deck to have teak water-ways, 12×5; teak decks, $3'' \times 5''$. The whole fastened to the beams with bolts and screws, every butt to have a screw-bolt. Stancheons of galvanised iron to be carried round the poop, with a teak rail on top. The poop to be fitted with suitable skylights, made of teak, fitted in the best style for light and ventilation; also to have round or square side lights in state-rooms, as may be required; to have side stairs, with brass rails, from the upper deck. The inside of poop to be fitted up in first style for passenger accommodation, and in accordance with a plan to be approved; to have two bath-rooms; also a water-closet for every eight passengers, side state-rooms, ladies' sitting cabin, captain's cabin and steward's pantry, with all the necessary furniture and fittings; the whole of the very best description of workmanship and material, as usual in large passenger steamers of the first-class.

Main-Deck.—On the main-deck a dining-room, to be entered by a spacious stair, either from inside of poop or from upper-deck, to be fitted with all the necessary furniture; a full set of dining-tables, sofas, settees, and chairs covered with morocco; to have mirrors, carpets, sideboards, stoves, lamps, swinging trays, &c., &c., and to have side state-rooms for first-class passengers, with carpets, curtains, sofas, wash-stands, &c., the whole arranged to a plan to be approved of.

Second-Class Accommodation.—To be fitted on main-deck forward for 100 passengers, with a water-closet for every 12 passengers, bath-room, &c. Saloon under spar-deck, of polished E. I. teak, with tables, settees, &c. The steward's bar and other conveniences all in the best manner.

Deck-House.—To have a strongly-fitted deck-house, as large as possible, consistent with other deck arrangements; to be constructed with iron-frames and beams, made fast to strong teak coamings, bolted to the deck-beams. The deck of the house to be of $2\frac{1}{2}$ inches yellow pine, with a side covering board to form moulding, of E. I. teak; the sides and ends to be of $1\frac{1}{2}$ inch yellow pine, half checked or feathered, and grooved; the house to be fitted according to a plan to be arranged and approved.

Officers' Accommodation.—To have accommodation for the officers, engineers, stokers, and stewards, with a sufficient number of water-closets and other conveniences, fitted on main-deck, between the first and second-class cabins, with separate ladder-ways, all as may be afterwards arranged.

Topgallant Forecastle.—To extend from the back of the figurehead of vessel to the fore side of the fore-hatch, being about 68 feet in length, and in height about 6 feet to 6 feet 6 inches; every alternate frame of the vessel at forecastle to be carried up to deck of forecastle, with reverse angle-irons, $4 \times 3 \times \frac{1}{2}$ inches, by piecing the present frames; to have an angle-iron stringer, $4 \times 4 \times \frac{1}{2}$ inches, with plates $18 \times \frac{1}{2}$ inches. The beams to be of bulb-iron, $7 \times \frac{1}{2}$, placed on every frame; these beams to be turned down at ends, to form knees, same as the other beams of the vessel; the beams to have an angle-iron, $2\frac{1}{2} \times 2\frac{1}{2} \times \frac{3}{8}$ inches, riveted on each side, for fastening down decks; to have two beam-ties riveted on top of plates, $12 \times \frac{1}{2}$; and that part of the forecastle deck where capstan comes through, to be all plated between the beam-ties; same to extend a sufficient length for strengthening that part of capstan; plating to be $\frac{7}{16}$ths thick, and to extend from gunwale of vessel to top of forecastle, and the whole length of forecastle with double riveted butt-joints. The decks to be of teak, $5\frac{1}{2} \times 3$ inches, with teak water-ways, $12 \times 4\frac{1}{2}$, well fastened down, caulked, and made water-tight; the part of deck at capstands to be well fastened and strengthened with teak planks, of increased thickness to those on deck; the top of forecastle to be fitted with all the necessary chocks, &c., required for a vessel of this class. The capstand for anchors to be double, and wrought on topgallant forecastle; but the stopper and riding-bitts to remain on spar-deck, as originally intended. The front of fore-

Practical Building.

castle to be neatly closed in and panelled, equal to bulwarks of vessel. The interior to be fitted up for crew, as may be directed by owners, with suitable brass side lights for ventilation.

Forecastle.—The crew to be accommodated in forecastle, under spar-deck, with berths, mess tables, &c., as may be required.

Lower-Deck Fittings.—The lower-deck, forward and aft, to be fitted with bullion-room, mail-room, wine-cellar, store-rooms, &c., as may be directed, all in the most approved manner.

On the main-deck, forward of second-class cabin, the remaining space to be fitted with butcher's shop, cabin for petty officers, and other necessary fittings, as may be directed.

Skylights.—The second-class cabin to be lighted and ventilated by skylights, fitted on cargo hatches, with suitable gratings, and other particulars as required.

Sundries.—All the locks, hinges, hat-hooks, &c., to be of brass, and fitted as required, and of the best description; to have complete sets of lamps for all the cabins, locks and bars for all the hatches and store-rooms; hen-coops, sheepfold, pig-sty, sets of

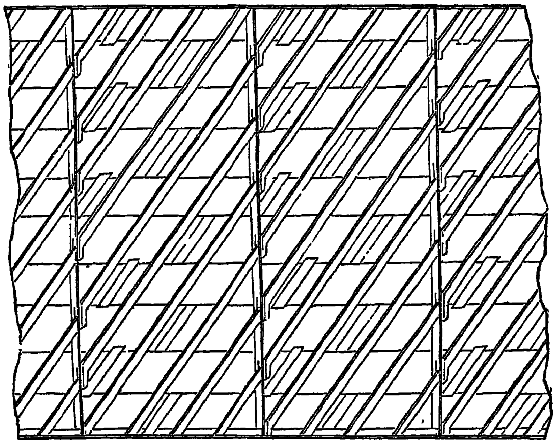

Fig. 60.

capstand bars for both capstands; four 60-gallon water-casks, four harness-casks, twenty-four buckets, twenty-four mess kids; four water-funnels, six breakers, four deck-tubs, and four tar-buckets; awnings for quarter-deck, with iron stancheons, binnacles, and bell-covers; skylight-covers and tarpaulines as required; iron bell-mouthed ventilators, and windsails for engine-rooms where required.

Taylerson's diagonal framing.

Messrs Taylerson and Company, of Port-Glasgow, have patented a diagonal arrangement of the frames of iron vessels. They substitute diagonal framing in the place of the ordinary vertical framing, or intersperse diagonal with vertical frames. The annexed figure shows the latter system of arrangement. No addition of strength, however, to the side of a ship will obviate the necessity for strength in the bottom and in the deck. If rupture were to take place at the top edge of the side, it may be doubted whether the diagonal frame would do more than divert the line of rupture into the sloping line between itself and the next frame. The same builders use a remarkably strong form of keel and keelson (fig. 61); and a representation of this is annexed, showing at the same time their mode of attaching the water-tight bulkheads; they introduce a piece of timber at each bulkhead, where it is attached to the ship's side, and fasten this by screws from the outside, with a view of lessening the number of rivet-holes. This most desirable object is no doubt attained, but great care must be taken that corrosion of the fastenings does not take place.

Arman's mixed system of wood and iron.

Mr L. Arman, of Bourdeaux, has constructed ships with diagonal iron framing inside a framing of wood of very light scantling, the sheathing of the ship being of wood. Inside the vessel, and attached to the iron frames, he introduced a series of horizontal stringers of plate-iron at intervals from the deck to the keelson, which is also of iron. This system imparts great strength to the framework of the vessel, and it is believed that it has, upon the whole, been very successful. Altogether the combination of wood with iron has been carried much further in France than in this country. Iron beams are being much used in their vessels, and iron rudder-pieces, the latter being very advantageous in men-of-war, from their smaller size.

Effects of Lloyd's register in ship-building.

Before closing these remarks, the influence or effects exercised upon the practical construction of ships by the rules of Lloyd's register require to be noticed, as they form a code of instructions to which all merchant-builders of this country are compelled to adhere. These rules are stated to be compulsory, because if a builder deviates from them, or ventures to differ in any point from the opinions of the surveyor, his vessel loses caste, either by being excluded altogether from the first class, or by being put on it for a less term of years. This does not suit the purchaser, and as there is no appeal from the decision of the surveyor, the builders must submit. In the first place,

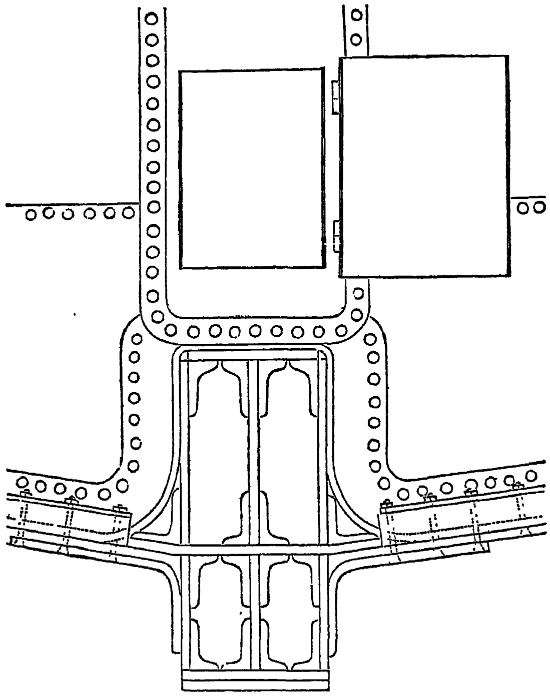

Fig. 61.

it may be remarked, that there is but one table of scantlings, &c., for ships of the same tonnage, while it is evident that the same rules as to scantling, &c., cannot be correct for the sharp long ship intended for carrying light cargoes, such as tea, wool, &c., and also for those which are intended for heavy dead-weights. Nor is any difference permitted in the scantlings of the timbers at the bow and at the stern of full or sharp ships. The rules do not directly interfere with the forms of ships, but in some respects they have undoubtedly indirectly militated against the production of fast-sailing vessels.

The supporters of Lloyd's register claim to themselves the credit of having improved the British mercantile marine; but, in the opinion of many experienced persons, its effect has been to produce a dead and spiritless mediocrity. That the construction of many very bad ships is greatly prevented is true, but there is no actually compulsory law to force every ship to be inspected and classed at Lloyd's, and many ships are sailed independent of any such inspection: its action in this respect, therefore, is not complete. On the other hand, it is equally true, that men of skill and talent are restrained from introducing improvements in the combination of materials. That this is the effect produced is well known; and as an instance, it may be mentioned, that on the first proposal being made to introduce iron beams into a wooden vessel, leave was refused unless the vessel was put into a lower class; and this improvement,

Practical Building.

which is now fully admitted by Lloyd's, was kept back for many years. It is natural that the general feeling of servants of the government, or of large public or joint-stock companies, should be against taking responsibility upon themselves by introducing or permitting changes; but it is much to be deplored if this spirit is brought into such a position as to be a drag upon the talent and energies of the whole nation. Shipowners who are not themselves practically acquainted with ship-building, take the natural course of adopting Lloyd's register as their standard. They contract for a ship to be built in such a manner that she may be put into the first class at Lloyd's, and they thus declare themselves ready to pay the cost of the builder's adherence to Lloyd's rules.

The ship-builder knows, perhaps, that he could introduce improvements, but he is unwilling to subject himself to the risk of a refusal by Lloyd's surveyors, and as the purchaser for whom he is working is satisfied, he builds accordingly. The want of encouragement by Lloyd's rules to increase the durability of ships has been before noticed. Under the existing rules, then, there seems to be reason to fear that the tendency of Lloyd's register has been to some extent to cause increased expenditure, to restrain improvement, and to uphold a dead and stagnant mediocrity. It is to be hoped that care will be taken to guard against the possible existence of such evils for the future.

On Launching.

Launching.

Ships are generally built on blocks which are laid at a declivity of about $\frac{5}{8}$ths of an inch to a foot. This is for the facility of launching them. The inclined plane or sliding plank on which they are launched has rather more inclination, or about $\frac{7}{8}$ths of an inch to the foot for large ships, and a slight increase on this for smaller vessels. This inclination will, however, in some measure, depend upon the depth of water into which the ship is to be launched.

While a ship is in progress of being built, her weight is partly supported by her keel on the blocks, and partly by shores. In order to launch her, the weight must be taken off these supports, and transferred to a movable base; and a platform must be erected for the movable base to slide on. This platform must not only be laid at the necessary inclination, but must be of sufficient height to enable the ship to be water-borne, and to preserve her from striking the ground when she arrives at the end of the ways.

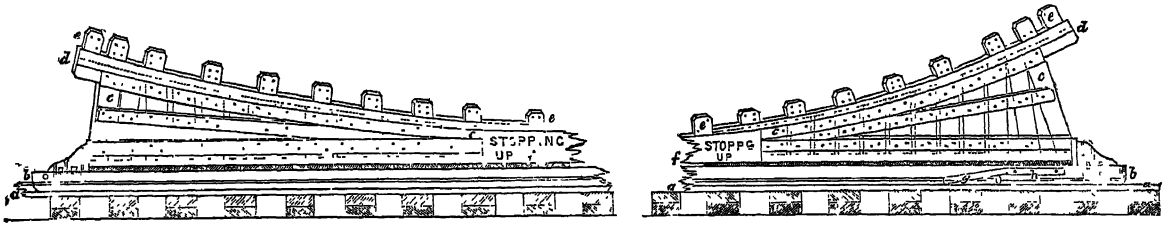

Fig. 62.

For this purpose, an inclined plane, *a*, *a* (figs. 62 and 63), purposely left unplaned to diminish the adhesion, is laid on each side the keel, and at about one-sixth the breadth of the vessel distant from it, and firmly secured on blocks fastened in the slipway. This inclined plane is called the sliding-plank. A long timber, called a bilgeway, *b*, *b*, with a smooth under surface, is laid upon this plane; and upon this timber, as a base, a temporory frame-work of shores, *c*, *c*, called "poppets," is erected to reach from the bilgeway to the ship. The upper part of this frame-work abuts against a plank, *d*, temporarily fastened to the bottom of the ship, and firmly cleated by cleats, *e*, *e*, also temporarily secured to the bottom. When it is all in place, and the sliding-plank and under side of the bilgeway finally greased with tallow, soft soap, and oil, the whole framing is set close up to the bottom, and down on the sliding-plank, by wedges, *f*, *f*, technically called slivers or slices, by which means the ship's weight is brought upon the "launch" or cradle.

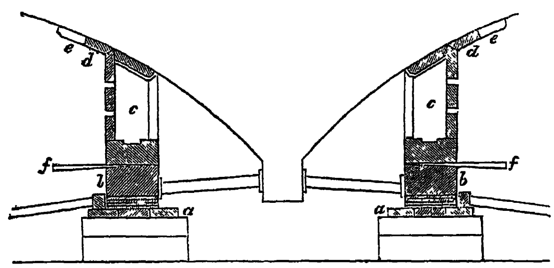

Fig. 63.

When the launch is thus fitted, the ship may be said to have three keels, two of which are temporary, and are secured under her bilge. In consequence of this width of support, all the shores may be safely taken away. This being done, the blocks on which the ship was built, excepting a few, according to the size of the ship, under the foremost end of the keel, are gradually taken from under her as the tide rises, and her weight is then transferred to the two temporary keels, or the launch; the bottom of which launch is formed by the bilgeways, resting on the well greased inclined planes. The only preventive now to the launching of the ship is a short shore, called a dog-shore (*g*), on each side, with its heel firmly cleated on the immovable platform or sliding-plank, and its head abutting against a cleat (*h*), secured to the bilgeway, or base of the movable part of the launch. Consequently, when this shore is removed, the ship is free to move, and her weight forces her down the inclined plane to the water. To prevent her running out of her straight course, two ribands are secured on the sliding-plank, and strongly shored. Should the ship not move when the dog-shore is knocked down, the blocks remaining under the fore part of her keel must be consecutively removed, until her weight overcomes the adhesion, or until the action of a screw against her fore-foot forces her off.

Launching on the keel.

A much less expensive mode of launching is now much practised in the merchant-yards of this country, and has been long in use in the French dockyards, allowing the keel to take the entire weight of the vessel. The annexed figure represents this method (fig. 64). The two pieces (*a a*), which are shown in the figure as being secured to the ship's bottom, are the only pieces which need be pre-

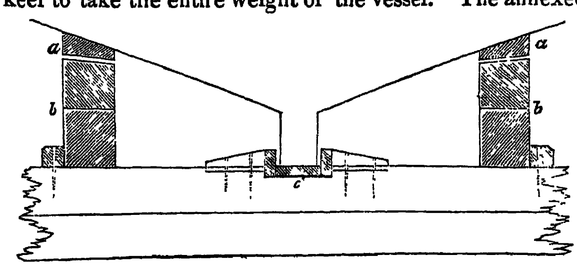

Fig. 64.

pared according to this system for each ship, the whole of the remainder being available for every launch. A space of about half an inch is left between them and the balk timber placed beneath them, as it is not intended that the ship should bear on these balk timbers in launching, but merely be supported by them in the event of her heeling over. The ship, therefore, is launched wholly on the sliding-plank (*e*), fitted under the keel. Messrs Hall of Aberdeen launched a vessel of 2600 tons in this manner without a single cleat upon her bottom or riband of any kind, and avoided all the making-up of the side-ways, except for about 60 feet in midships for keeping the ship upright. The centre-way was hollowed, and a round sliding-way fitted in it, and the keel was thus supported from end to end. This may, therefore, be considered to be the safest, cheapest, and easiest mode of launching long sharp ships.

If a ship is coppered before launching, so that putting her

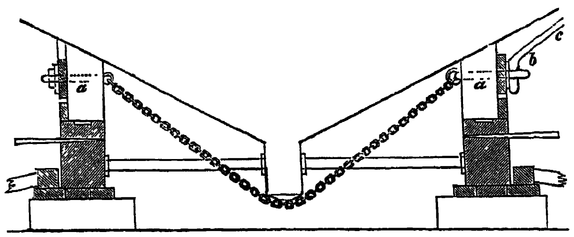

Fig. 65.

into a dry-dock for that purpose becomes unnecessary, it is then desirable that she should be launched without any cleats attached to her bottom. This method of fitting the launch, as represented in figure 65, is then adopted for this purpose. The two sides of the cradle are prevented being forced apart when the weight of the ship is brought upon them by chains passing under the keel. Each portion of frame-work composing the launch has two of these chains attached to it, and brought under the keel, to a bolt *a*, which passes slackly through one of the poppets, and is secured by a long forelock *b*, with an iron handle (*c*), reaching above the water-line, so that when the ship is afloat it may be drawn out of the bolt. The chain then draws the bolt *a*, and in falling trips the cradle from under the bottom. There should be at least two chains on each side secured to the fore-poppets, two on each side secured to the after-poppets, and two on each side to the stopping up, and this only for the launch of a small ship: in larger ships the number will necessarily be increased according to the weight of the vessel and the tendency that she may have, according to her form, to separate the bilgeways. This tendency on the part of a sharp ship by a rising floor, or by her wedge-shaped form in the fore and after bodies, is great, but there is not much probability of a ship heeling over to one side or the other.

It is recorded that upon one occasion of our sailors having taken possession of an enemy's arsenal, and finding a vessel on the stocks nearly completed, they removed the shores from one side, and tried to upset her by wedging up the shores on the other side, but were unable to do so. There appears, therefore, to be no valid objection to the cheaper and more ready method of launching on the keel. (A. M—Y.)

SHIRAZ, a city of Persia, formerly capital of the whole country, and now of the province of Fars, 115 miles E.N.E. of Bushire. It stands in a wide plain, 25 miles long by 12 broad, enclosed by bare limestone mountains. The greater part of the plain is stony and barren; but a large portion has been brought under cultivation. The immediate vicinity of Shiraz is celebrated for its beauty and fertility, and is occupied with extensive suburbs and gardens. The town itself is encircled by walls $3\frac{3}{4}$ miles in circumference; and entered by six gates, each flanked by two towers. Formerly there were here a large palace, numerous mosques, colleges, bazaars, and caravanserais; but the aspect of the place has been entirely changed by the earthquake which took place in April 1853, by which nearly the whole town was laid in ruins. Previous to this earthquake there had been others nearly equally destructive in 1812 and 1824. Besides these, and other natural disasters, the town has suffered very much from the oppression of its rulers, so that it is now reduced to a very wretched condition. One of the gates is named after the poet Sadi, who was born here in 1149 A.D., and died here also at the age of one hundred and twenty. He is buried in a mausoleum, 22 miles to the N.E. of Shiraz. About half a mile N.E. of the Ispahan gate of the city is the tomb of Hafiz, the Anacreon of Persia, also a native of Shiraz. The most remarkable commodity of the place is wine, of which there are two kinds. Its seal-engravers are very famous in Persia; and it has also manufactures of silk and cotton goods, firearms, cutlery, and earthen-ware. Its trade, too, is very considerable, as it stands on the routes from the port of Bushire to Kerman, Yezd, and Ispahan, in the interior. According to Persian legends, Shiraz was built by Janshid; but history makes Hadji bin Yusuf its founder, A.D. 697. The principal mosque was built by Atabah Sad Zanzi, A.D. 1226; but the greatest benefactor of the town was Kerim Khan, who lived towards the end of the eighteenth century. Since that time the place has gradually declined. In the vicinity lie the remains of many splendid ancient buildings; and about 25 miles N.E. are the ruins of Persepolis. Pop. 30,000, including about 400 families of Jews.

SHIRE (Anglo-Saxon *Scyran* to divide, whence also to shear, shears, sheer, shore, shirt, skirt, &c.), a territorial division, cut off or divided from the surrounding country. As ordinarily applied now-a-days, it is synonymous with COUNTY (which see); but certain districts in England still preserve traces of the original meaning of the word. For example, Richmondshire, in the North Riding of Yorkshire; and Hallamshire, which is nearly co-extensive with the parish of Sheffield.

SHIRLEY, JAMES, a successful English dramatist, was born in London on the 13th September 1596. He had his education at Merchant Taylors' School, London, and at St John's College, Oxford, where he gave signal marks of future distinction. The duration of his residence at this university cannot now be ascertained, as the public records of Oxford do not mention his name. He next proceeded to Catherine Hall, Cambridge, where he took his degree. His earliest publication was a poem, entitled, *Echo, or the Infortunate Lovers*, which appeared in 1618, and which was in all probability the same as the *Narcissus* of 1646. Having finished his academical course, he adopted the ecclesiastical profession, and was appointed to a living in or near St Alban's, Hertfordshire, which he shortly resigned, from his having become a convert to Roman Catholicism. Resigning the clerical profession, he taught for some time during the years 1623 and 1624 in the Grammar School of St Albans. Disliking the drudgery of tuition, he went up to London, lived in Gray's Inn, and devoted himself to the composition of plays. *Love Tricks, or the School of Complement*, was his earliest production. It was published in 1631, but had been licensed five years earlier. It was evidently a youthful production, but it gave good promise of future excellence in the peculiar walk which he had chosen. Of the thirty-three regular dramas which flowed from his exuberant invention, there are great varieties of

Shirvan. excellence. Unquestionably his highest effort was the *Traitor*, licensed in 1631 and published in 1635. "Assuredly, since his decease," says Dyce, "no tragedy of equal excellence has graced the British stage." The truth and vigour which waited on his pen in the composition of this drama must have disliked the work, for they seem in a great measure to have deserted him on its completion. This play was plagiarized by one Rivers in 1692, and has been frequently revived. It was partly recast by Richard Sheil, in his *Evadne, or the Statue*, which was acted with success at Covent Garden in 1819. Shirley, however, who should have been a good judge of the quality of plays, esteemed his *Cardinal*, which was published in 1652, as "the best of his flock."

In September 1642, an order went forth from both Houses of Parliament for the suppression of stage plays throughout the kingdom; and Shirley, who was a monarchist, gave in his adherence to his munificent patron, the Duke of Newcastle, whom he had assisted largely in the composition of his plays. The King's cause declining, and the dramatist's prospects being of the gloomiest description, he retired obscurely to London, where he contrived, by industriously pursuing his former occupation of a teacher, to support his wife and family for the remainder of his days. He was solaced by the intimate friendship of Thomas Stanley, author of the *History of Philosophy*, and of Sir Edward Sherburne, now principally remembered by his translation of a portion of *Manilius*. Of Shirley's competency for this office, he has left us a pledge in his excellent grammatical treatises. With the exception of giving occasional assistance to John Ogilby in his literary undertakings, Shirley seems to have henceforward renounced the use of his pen. The restoration of Charles II. could not prevail upon him to break his resolution, and while the degenerate race of playwrights hurried eagerly forward to hold up their bombast and obscenity to that licentious age, the gentle and modest old Shirley wore out the remainder of his days away from the corruption of the court and the dissolute practices of his compeers. Shirley was burned out of his house in Fleet Street by the great fire of London in 1666, and being obliged to withdraw to the suburbs, he and his wife, overcome with fright and fatigue, both died in the same day (October 29), and were buried in the same grave. The orphan children of the dramatist were most probably thrown destitute on the world. In Anthony à Wood's day, one of his sons held the office of butler at Furnival's Inn. *Sic transit gloria mundi!*

Dryden has satirized Shirley in his *MacFlecknoe*, but he possessed much greater merits than his appearance there would imply. His language is always correct, and his invention sometimes successful; but he has only a limited stock of the objects of fancy to draw upon. His humour, however, is broad and genial; his wit is sometimes sprightly, but more frequently strained; his characters are well drawn, although he never rises into any of the nicer shades which discriminate one personality from another. He delineates passion well, yet he is better at the description of it than he is in making us feel the thing itself. His plays, although many of them well worth reading, are no longer acted. He had not the anticipatory genius, enabling him to delineate with words the passions of men throughout all times. This prerogative was given to Shakspeare alone of all our English dramatists. The best edition of Shirley's *Dramatic Works and Poems* is that of Gifford and Dyce, 6 vols. 8vo, London, 1833.

SHIRVAN, a province of Asiatic Russia, in the country of the Caucasus, bounded on the north by the province of Daghestan, from which it is separated by the Caucasus, E. by the Caspian, S. by Persia, and W. by Georgia. It lies between N. Lat. 40. and 41.; E. Long. 48. and 49. 30. A range of mountains traverses the province from N.W. to S.E., separating the valley of the Kur, which forms the southern frontier, from that of the Terek. The northern portion is level, fertile, and well wooded; watered by numerous affluents of the Kur. The climate is warm, especially about the delta of the Kur, where the soil is very fertile, and would produce, if properly cultivated, many tropical plants. Rice, silk, wine, cotton, and tobacco are the principal productions of Shirvan. On the coasts of the Caspian there are valuable fisheries. The chief manufactures are those of silk at Shamaka, the largest town in the province. In the mountainous regions arms and other metal fabrics are made. The inhabitants are almost all of the Tartar or Turkish race, with a slight mixture of Arabs and Persians. The majority are Mohammedans, but there are also some Jews and Armenians. The language is the Turkish, which is also used in Azerbijan. Shirvan formed until the sixth century a part of the monarchy of Armenia; but was afterwards conquered by the Persians, and made a part of that empire under Khosroo Nooshirvan, who called this country after his name. But at a subsequent period it was governed for some time by independent princes, who in the ninth century acknowledged the supremacy of the Caliphs. The rulers of Shirvan, however, long retained much power, and carried on many wars with Persia, over which country they repeatedly gained great advantages. Finally, in the end of the fifteenth century, it was completely brought under the Persian sway. The Russians gradually invaded the country; and it was ceded to them in 1812. Under their dominion it first formed the Caspian province, but was divided in 1847 into the governments of Shamaka and Derbent; the former of which in 1851 had 603,006, and the latter 453,284 inhabitants.

Shishkoff. SHISHKOFF, Alexander Semenowitsch, a Russian author, admiral, and statesman, knight of several orders, and president of the Russian Academy, was born in 1754, and was educated at the Naval Cadet Corps. Having entered the naval service, he subsequently visited, both professionally and privately, Sweden, Denmark, England, Germany, Italy, and Turkey. He began his career of authorship while a cadet in the navy, by executing translations, poems, and dramas. In his later years he devoted his attention exclusively for long years to the benefiting of persons connected with the naval service of Russia. His *Naval Service*, St Peterburg, 1793; his *Marine Lexicon*, St Petersburg, 1795; his *Collection of Journals during Voyages at Sea*, St Petersburg, 1800; and his *Historical Records of the Navy*, published some time after, all belong to this class. After an estrangement of twenty years, he returned to pure literature, the darling of his early years. His effective, but too hasty book, *Considerations on the Old and New Styles of the Russian Language*, appeared in 1802, and has been frequently reprinted. His *Additional Remarks* to this volume appeared in 1804, and the *Essays of La Harpe* in 1808. A tart review of this work occasioned a series of replies and retorts, which wound up with *The Easiest Way of Replying to a Criticism*, 1811, from the pen of the reviewer, and is acknowledged to be one of the most acute works of a polemical nature in the Russian language. In 1811 appeared Shishkoff's *Dialogues on Literature*, and in 1812 he was made secretary of state, in which capacity he accompanied the Emperor Alexander, and gleaned the materials of his *Memoirs of the War in* 1812, published in 1816 at St Petersburg. The latter work is perhaps the best which he has written. It overflows with patriotism and zeal for the glory of Russia, and is written in a strain of high-wrought, fervid eloquence. In 1818 appeared his prose translation of Tasso's *Gierusalemme Liberata*, which closed his public career of authorship. Many of his later writings are reported to be still in manuscript; and if one can trust to the intelligence which rumour conveys, they had better remain so. Shishkoff

died in 1841, and his works appeared in 14 vols. in 1823–34.

SHITOMIR. See JITOMIR.

SHOA, or SHWA, a state of Abyssinia, in the south-east of that country, lying between N. Lat. 8. 30. and 11., E. Long. 38. and 40. 30., and extending from the river Hawash, which separates it from the country of the Gollas on the south, to its affluent the Berkona, and to the Wanshit, a tributary of the Abai, which separate it from Amhara on the north. The country is very elevated, and attains on the south and east a height of 9000 or 10,000 feet above the sea. Towards the south the land gradually declines to the broad plain watered by the Hawash; towards the east the descent is much steeper; while the centre and west of the country is occupied by the valley of the Jamma, sloping by degrees to the height of about 3000 feet, which that river has at its confluence with the Abai. Both on the north and on the south of this valley there are high mountains, rising 4000 or 5000 feet above its surface. The Jamma is the principal river in the land, and receives many affluents from the south. These divide the table-land through which they flow into a number of narrow ridges, since many of them flow through deep ravines, interrupted by numerous cataracts. The loftier parts of the country are in many places well cultivated, producing large crops of wheat and barley, and are studded with numerous villages and trees; but there are also extensive regions used only for pasturage. The climate is cool and healthy, sometimes exceedingly cold. In the lower ground, where the temperature is higher, cotton is largely grown. Many of the valleys of Shoa are exceedingly beautiful, with a luxuriant and even gigantic vegetation; but the climate here is very hot and unhealthy. Among the mineral productions of the country coal is the most important; some metals have also been found, as well as sulphur, nitre, and alum. The vegetable productions include dyewoods, drugs, indigo, and coffee, besides those already mentioned. Almost the only manufacture is a coarse kind of cotton cloth, which is made in large quantities at every farm. A considerable trade is carried on, chiefly through Zeila, which is the nearest port, not far from the Strait of Bab-el-mandeb. The exports comprise the produce of the surrounding countries, as well as of Shoa itself, such as ivory, spices, and gold-dust. The country is governed by a king, and the population amounts to 1,500,000, including heathens, Mohammedans, and Christians.

SHOE, a covering for the foot, usually of leather. Shoes among the Jews were made of leather, linen, rush, or wood; those of soldiers were sometimes of brass or iron. They were tied with thongs, which passed under the soles of the feet. To put off their shoes was an act of veneration; it was also a sign of mourning and humiliation. To bear one's shoes, or to untie the latchets of them, was considered as the meanest kind of service.

Among the Greeks, shoes of various kinds were used. Sandals were worn by women of distinction. The Lacedæmonians wore red shoes. The Grecian shoes generally reached to the middle of the leg. The Romans used two kinds of shoes; the *calceus,* which covered the whole foot, somewhat like our shoes, and was tied above with latchets or strings; and the *solea,* or sandal, which covered only the sole of the foot, and was fastened with leathern thongs. The calceus was always worn along with the toga when a person went abroad; sandals were put on during a journey and at feasts, but it was reckoned effeminate to appear in public with them. Black shoes were worn by the citizens of ordinary rank, and white ones by the women. Red shoes were sometimes worn by the ladies, and purple ones by the coxcombs of the other sex. Red shoes were put on by the chief magistrates of Rome on days of ceremony and triumphs. The shoes of senators, patricians, and their children, had a crescent upon them, which served for a buckle; and these were called *calcei lunati.* Slaves wore no shoes, and hence they were called *cretati,* from their dusty feet. Phocion also and Cato of Utica went without shoes. The toes of the Roman shoes were turned up in the point; and hence they were called *calcei rostrati.*

In the ninth and tenth centuries the greatest princes of Europe wore wooden shoes, or the upper part of leather and the sole of wood. In the reign of William Rufus, a great beau, Robert, surnamed the Horned, used shoes with long sharp points, stuffed with tow, and twisted like a ram's horn. It is said that the clergy, being highly offended, declaimed with great vehemence against the long-pointed shoes. The points, however, continued to increase, till in the reign of Richard II. they were of so enormous a length that they were tied to the knees with chains, sometimes of gold, sometimes of silver. The upper parts of these shoes were in Chaucer's time cut in imitation of a church-window. The long-pointed shoes were called crackowes, and continued in fashion for three centuries, in spite of the bulls of popes, the decrees of councils, and the declamations of the clergy. At length the parliament of England interposed by an act passed in the year 1463, prohibited the use of shoes or boots with pikes exceeding two inches in length, and forbade all shoemakers from making shoes or boots with longer pikes, under severe penalties. But even this was not sufficient. It was necessary to denounce the dreadful sentence of excommunication against all who wore shoes or boots with points longer than two inches. The present fashion of shoes was introduced in 1633, but the buckle was not used till 1670. The customary shoe of the American Indians, known as the moccasin, is generally made of deer-skin or other soft leather, and is without a sole, but ornamented on the upper side.

SHOLAPORE, a collectorate of British India, in the presidency of Bombay, lying between N. Lat. 16. 10. and 18. 34., E. Long. 75. and 76. 28.; bounded on the N. and E. by the Nizam's dominions, S. and S.W. by the collectorates of Belgaum and Sattara, W. and N.W. by those of Poona and Ahmednuggur. Its length from N.W. to S.E. is 170 miles; greatest breadth, 50; area, 4991 square miles. The country is undulating, presenting a series of hills and valleys, with comparatively few trees. Its chief rivers are the Kestnah, which washes the southern border, the Bheema and the Seena. The soil is admirably adapted for the growth of cotton, which is the principal crop raised. There is a great want of internal communications, as there is no good road in any part of the country; while the rivers Bheema and Seena, when swollen at the time of the monsoons, offer serious impediments in the way of travelling. Considerable care has been bestowed on agriculture; but as European implements have not yet been generally introduced, there are still great deficiencies, both in the cultivation of the soil and in the mechanical arts. Sholapore was acquired by the East India Company in 1818, after the fall of the Peishwa. It was at first included in the collectorate of Poona, but in 1838 formed into a separate collectorate. Pop. 675,115.

SHOLAPORE, the capital of the above collectorate, stands in a level tract near its eastern extremity, 165 miles S.E of Poona and 220 S.E. of Bombay. It is a place of no natural strength, but has been so strongly fortified as to be of much importance in a military point of view. It is oblong in form, surrounded by a substantial stone wall, and a broad deep ditch, outside of which, on the north and east, is a suburb, also fortified; while on the south the ditch expands into a tank, with a mound on three sides of it. A church has been built here, but there are no other important edifices. Sholapore has frequently changed masters in the early periods of Indian history. It was taken by escalade in 1818, by a British force under General Pritzter.

SHOOTING.

The pursuit and destruction of wild animals for security, food, clothing, or pastime, have been amongst the occupations of men in all ages, since the primeval *bruerè* overspread the earth,

> And wild in woods the noble savage ran.

Before the more refined arts are introduced into any country, the chase is a necessity, and the chief business of life. The stronger and more noxious animals are destroyed for individual safety; the weaker for food. It is not until civilization and her handmaid luxury have seated themselves, that the chase becomes a pastime. It does not appear when the sportsman first sprang into existence. There is no corresponding word in any ancient language, since that could not be called a sport which was a necessity. It is probable that in the earliest ages of society the dog was the sole agent employed by the hunter. Afterwards various weapons, manual, missile, and projectile, as the club, the dart, the arrow, were used by the hunter and fowler. Then would follow springes, traps, nets, and all that class of devices for the capture of beasts and birds *feræ naturæ*, comprehended in the term toils. As dogs were employed to hunt quadrupeds, so, in process of time, hawks were trained to bring down birds for the service of their master. The arbalest, or cross-bow, preceded the matchlock, which, however, could scarcely be called an implement of the chase, but which, in the order of succession, brings us down to the rifle, and original fowling-piece with its long heavy barrel and flint and steel lock; and, lastly, we arrive at the double barrels and detant locks of the modern shooter.

In the days of the Saxon and Norman kings, and long previously, the Britons were famous for their skill in archery, both in war and in the chase. The feats of the bow were often introduced into the songs of the bards of the ancient Britons, and into the ballads of the Troubadours.

Archery.

Archery is now confined to shooting at the target. Ladies not unfrequently contend for the prize in this elegant amusement. Their bows, however, are not such as were used by the amazons of yore, nor are those of the gentlemen of the archery clubs such as decided the battle of Cressy.

Falconry.

Falconry, coeval with, and subsequent to the decline of archery, occupied that rank in British field sports which is now enjoyed by shooting. Falconry is of high antiquity; but at what time hawks were first trained to the sport does not appear. Aristotle informs us that "there was a district in Thrace, in which the boys used to assemble at a certain time of the year, for the sake of bird-catching; that the spot was much frequented by hawks, which were wont to appear on hearing themselves called, and would drive the little birds into the bushes, where they were caught by children; and that the hawks would even sometimes take the birds and fling them to these young fowlers, who, after finishing their diversion, bestowed on their assistants part of their prey." Martial has the following epigram on the fate of a hawk:

> Prædo fuit volucrum, famulus nunc aucupis, idem
> Decipit, et captas non sibi, mœrit, aves.

There is no record of trained hawks previous to the time of Ethelred. Under the Welsh laws of Hoel Dha, (A.D. 940), "the falconer has a privilege, the day that the hawk shall bill a bittern, or a heron, or a curlew. Three services shall the king perform for the falconer on such a day; hold his stirrup whilst he dismounts; hold the horse whilst he goes after the birds; and hold his stirrup whilst he mounts again. Three times shall the king that night compliment him at table." Shakspeare often uses the language o. falconry. It is chiefly employed in a scene in the second part of Henry VI., wherein the king, queen, lord protector, and cardinal, are the chief speakers; which goes to prove, that the falconer's terms were, at one time, household words at the English court.

Shooting.

Hunting and archery.

Hunting and archery, which were then almost synonimous terms, (for the sport was somewhat similar to what deer-stalking now is, the rifle being substituted for the bow,) were in high repute with the Danish, Saxon, and Norman kings, whence arose the forest laws. Wolves and boars, which formerly infested the forests, were nearly exterminated in king Edgar's time, when that monarch prohibited the killing of deer and game in his woods. The punishment depended upon the will of the king, until the celebrated forest laws of Canute, which defined the rights and privileges of the monarch and others; but those laws were little regarded by succeeding kings, whose arbitrary will afterwards regulated the laws of the forest. "Besides other prerogatives of the Saxon kings," says Selden, "they had a franchise for wild beasts for the chase, which we commonly call forest, being a precinct of ground, neither parcel of the county, nor the diocese, nor the kingdom, but rather appendant thereto." And these prerogatives, he quaintly observes, were maintained, "that the world might see the happiness of England, where beasts enjoy their liberty as well as men." Another old writer says, that "the Saxon kings and the Danish king Canute made no new forests, but were contented with the woods that were their own demesnes, and were never granted to, or possessed by the subject; but the kings of the Norman race, not being satisfied with sixty-eight old demesne woods or forests, depopulated well-built towns and villages, to make to themselves places appropriated to their own diversion only. William the Conqueror laid waste thirty-six towns in Hampshire to make a forest, which still retains the name of the New Forest; and his forest officers exercised such arbitrary rule, as to abridge even the great barons of the privileges they enjoyed under the Saxon and Danish kings, not at all regarding the liberties given to the subject by Canute's forest laws. His son William Rufus is recorded in history for the severity of his proceedings against all that hunted in his forests, inflicting the punishment of death upon such as killed a stag or buck in his forests, without any other law than that of his own will." The killing of deer was punished with loss of sight by William the Conqueror.[1] William Rufus "did so severely forbid hunting a deer, that it was felony and a hanging matter to have taken a stag or buck."[2] In Cœur de Lion's time, the law was very severe against offenders taking the king's venison; it was even unlawful to carry a bow, or take dogs through a royal forest. "Qui arcus vel sagittas portaverint vel canes duxerint sine copulâ per forestam Regis, et inde attaintus fuerit, erit in miserecordiâ Regis."[3]

The forest laws professed to be for the protection of "vert and venison." *Vert* was whatsoever bore green

[1] John Selden. [2] William of Malmsbury. [3] England's Epinomis, p. 34.

leaves, and afforded food or cover to the deer; and *venison* signified such beasts of the forest or the chase as were the food of man. When reading old books, it is necessary to keep in mind this acceptation of the word venison.

This state of things continued until by the Charta de Foresta the forest laws were better defined and the penalties mitigated. The vast importance attached to the Forest Charter may be inferred from the fact, that although granted by king John at Runnymede, at the same time as the Great Charter, it was not incorporated in it, but was made the subject of a separate and distinct document. The Forest Charter was likewise confirmed by Henry III., contemporaneously with the Great Charter. On the latter occasion the Forest Charter was counter-signed by sixty-four bishops, abbots, and barons; and sentence of excommunication against all persons who should violate it was, with great ceremony, denounced in Westminster Hall, by the archbishop, in the presence of the king, bishops, and nobles, the bishops being robed and bearing torches.

The oath administered, at twelve years of age, to every young man dwelling within the precincts of a royal forest, was in the following rhymes:

> You shall true liege-man be
> Unto the King's Majesty:
> Unto the beasts of the FOREST you shall no hurt do,
> Nor to anything that doth belong thereunto:
> The offences of others you shall not conceal,
> But to the utmost of your power, you shall them reveal
> Unto the OFFICERS of the FOREST,
> Or to them who may see them redrest:
> All these things you shall see done,
> So help you GOD, at his HOLY DOOM

After the Forest Charter was granted any one was allowed to kill game, except in the royal and other forests, and certain other privileged places,[1] until the reign of Richard II., when a landed qualification of forty shillings per annum became necessary to entitle a person to keep "any greyhound, hound, dog, ferret, net, or engine, to destroy deer, hares, conies, or any other gentleman's game." The qualification required was increased with the improved value of land, from time to time, until, in Charles the Second's reign, it was enacted, that persons not having L.100 per annum arising from freehold, or L.150 from leasehold property, or not being of the degree of esquire, or otherwise privileged, should not keep or use "any guns, bows, greyhounds, setting dogs, ferrets, coney-dogs, lurchers, hays, nets, lowbels, hare-pipes, guns, snares, or other engines for taking or killing game."

It was not until the early part of the reign of George III. that killing game was taxed as a luxury, and made a source of revenue to government. A tax of two guineas was first imposed on all persons who should go out in pursuit of game; but the price of the certificate was afterwards raised to three guineas, and subsequently to three and a half guineas. The property qualification is abolished, and now any person who has taken out a certificate and obtained permission from the owner or tenant of the land, in which soever the right at the time may happen to be, is privileged to kill game at all seasonable times. During a long period the sale of game was prohibited, which gave a peculiar value to it, as it was not attainable by any but qualified and certificated persons and their friends, except by indirect means. It is now publicly sold by persons taking out licences for the purpose, and such licenced persons are liable to penalties, and are incapacitated from renewing their licences, should they purchase game from any but duly certificated sportsmen. The licenced dealers are, however, largely supplied by poachers, notwithstanding the penalties to which they subject themselves by trading with uncertificated persons.

Falconry fell into dissuetude in the days of the Georges. It is now scarcely known but by name, although the honorary distinction of hereditary Grand Falconer of England is still extant. As falconry fell into disuse, another kind of sport, which is now considered as disreputable, and practised only by poachers, was pursued by the country gentlemen; the capturing of birds of the game species by means of nets and setting dogs. The dogs were trained to lie down when near to game, and to suffer the net to be drawn over them, so that both dog and birds were entangled in the toil. In this manner partridges are still frequently taken by poachers in the night. A poacher's dog is sometimes known by his habit of crouching when close upon game, and this circumstance not unfrequently leads to a detection of the practices of his master. Netting was considered as a fair mode of taking game until the fowling-piece came into general use.

On the accession of the house of Hanover to the throne of Great Britain, falconry, netting, and shooting, were contemporary amusements. The number of shooters was very limited, the inferiority of the guns and ammunition being such as not to induce their general adoption; hawking was going out of favour; and, of the three sports, netting was the most commonly practised, until the beginning of the reign of George III., after which time it was no longer deemed the sport of gentlemen. At what time the fowling-piece first came into use is uncertain. We learn from Pope that pheasant shooting was in vogue in Windsor forest during the reign of Anne.

Shooting, as practised with guns to which flint and steel locks were attached, may be said to have risen and fallen with the Georgian era. During the latter part of that period, great improvements were made in all the implements and materials of shooting. Double barrels came into use, horse-nail stubs were employed in the manufacture of

---

[1] The places privileged were of four descriptions, viz. a forest, a chase, a park, and a warren. To these may be added a decoy for water-fowl, which had also peculiar privileges.

"A *forest* is a certain territory of woody grounds and fruitful pastures, privileged for wild beasts and fowls of forest, chase, and warren, to rest and abide there in the safe protection of the king for his delight and pleasure; which territory of ground so privileged is meered and bounded with unremoveable marks, meers, and boundaries, and replenished with wild beasts of venery or chase, and with great coverts of vert for the succour of the said beasts there to abide; for the preservation and continuance of which, there are particular officers, laws, and privileges belonging to the same, requisite for that purpose, and proper only to a forest and no other place." *Manwood's Forest Laws*, p. 143. "Beasts of forest are properly hart, hind, buck, hare, boar, and wolf, but legally all wild beasts of venery." *Coke's Institutes*, vol. i. p. 233. "A purlieu is a portion of a forest which was disafforested by the Charta de Foresta." *Manwood*, 242.

"A *chase* is a privileged place for receipt of deer and beasts of the forest, and is of a middle nature, betwixt a forest and park. It is commonly less than a forest, and not endowed with so many liberties, as officers, laws, courts, and yet is of a larger compass than a park, having more officers and game than a park. Every forest is a chase, but every chase is not a forest. It differeth from a park in that it is not inclosed." *Manwood*, 49, 147. "Beasts of the chase are, the buck, doe, fox, martern, and roe." *Manwood*, 144.

"A *park* is a large parcel of ground privileged for wild beasts of chase by the king's grant, or by prescription. A park must be inclosed." *Read. Game.* "The beasts of park properly extend to the buck, doe, fox; but in common and legal sense to all the beasts of the forest." *Read. Game.*

"A *free warren* is a place privileged by prescription or grant of the king, for the preservation of the beasts and fowl of the warren, viz. hares, conies, partridges, and pheasants." *Manwood*, p. 44. "If a pheasant, or other bird of warren, flew into a free warren, the falconer could not follow it, but it became the property of the owner of the warren." *Manwood*.

A *decoy* for wild fowl is to this day privileged, in so far as the owner has the exclusive right to the birds frequenting it; and no person is allowed to fire a gun or otherwise make a disturbance within a reasonable distance of it, without permission from the owner.

Shooting. barrels, the patent breech and percussion-cap were invented, and the wire-cartridge has since been introduced. Not the least improvement has been that in the manufacture of gunpowder. The excellence of our guns and dogs has tended much to spread the love of shooting, which has become the most popular and universal of British field sports.

It has been remarked, that England (Great Britain) is peculiarly the land of sportsmen, the very name being unknown in all other countries. The observation is in a great measure true, for, if we look around the globe, we find that wherever wild animals are killed for the sake of sport, it is mostly by the Englishman. In Sweden the Englishman alone kills the bear for sport. The natives kill it for the sake of reward, or to rid themselves of a noxious neighbour. Their method is generally thus: The strength of the country is summoned *en masse*, and several hundreds of people armed, form a circle many miles in circumference, and march forward until they meet in the centre, by which means great numbers of bears, wolves, and lynxes are destroyed. But this is not done for sport; it is a compulsory matter, and the people engaged in it are paid by the government; it is a species of feudal duty, which the able-bodied are called upon to perform whenever public safety requires it. In Asia, the only sportsman that encounters the royal tiger is the Englishman; the native shekerrie shoots the tiger for profit. There also the buffalo and the boar are hunted by the Englishman alone. In Africa, it is the Englishman who hunts the lion, the hippopotamus, and the giraffe. And in America, it is the Englishman, or English settler, who hunts the panther, the bison, and the bear, for sport; the natives do so from necessity. Since, then, the Englishman is the universal sportsman, it behoves the officer, the emigrant, and the tourist, to make themselves acquainted not only with what may be called the first principles of sporting, but more especially with the sports peculiar to the countries to which they are proceeding, a theoretical knowledge of which may be gleaned from the volumes which annually proceed from the pens of our adventurous countrymen.

The Rifle. THE RIFLE. The only fire-arms used by the sportsman are the rifle, the musket, and the fowling-piece; the latter may be classified into the swivel-gun, which is fired from a rest, and the shoulder-gun. A short, wide-bored musket, charged with a round or oval iron ball, was formerly used for the destruction of such animals as the lion, tiger, or bear. In modern times, the musket has been superseded by the rifle, and the iron ball by a leaden one, hardened with tin and weighted with quicksilver. A short piece is said to be preferred to a long one for shooting tigers, bears, and the like, as it may be more readily loaded, and is more easily managed in cases of emergency; indeed we apprehend the shooter should seldom fire, except when the animal is so near to him that if he aim coolly, he can scarcely fail to lodge a ball. We subjoin the method of taking aim at wild beasts from practical sporting writers. Captain Williamson gives the following instructions for shooting tigers:[1] "If the motion of an animal through the grass be perceived, the nearest elephant should be halted; and its left shoulder being pointed towards the moving object, is the most favourable position for taking a good aim. The hunter should fire without hesitation, observing to proportion his level as far within the space between himself and the tops of the yielding grass as the height of the cover may dictate; by this precaution, equally necessary when shooting fish that are in any degree beneath the surface of the water, the iron ball will, in general, take effect." Mr. Lloyd says,[2] "If a man purposes attacking a bear at close quarters, a double gun is decidedly the best; if it be in the winter season, a detonator is very preferable. Owing to having flint locks, both my barrels, on one occasion, missed fire, which might have been attended with most serious consequences; a large ball is very desirable. The best points to hit a bear, or any other animal, are in the forehead, in the breast, under the ear, or at the back of the shoulder; bullets placed in other parts of the body of an old bear usually have little immediate effect. If the snow be deep, and the bear is crossing a man, he should always aim very low; he must often, indeed, fire into the snow, if he expects to hit the heart of the beast."

In 1826 it was found necessary to destroy an elephant in Exeter 'Change. A detachment of foot guards were called in, and directed by surgeons where to fire; and 152 bullets were fired before it was disabled. This proves how utterly ineffectual the leaden musket ball would be in the forest. Captain Harris, in his South African tour, in 1837, took with him a double-barrelled rifle, carrying balls two ounces weight, and thus armed, no beast could stand before him. Speaking of the forehead of the elephant, he says,[3] "A ball hardened with tin or quicksilver readily penetrates to the brain, and proves instantaneously fatal." He gives instances of his killing large elephants at a single shot, and seems to have had no difficulty with the "king of beasts," which he has slain "in every stage from whelphood to imbecility." According to Captain Harris, travelling through countries infested by wild beasts is not so dangerous as it is commonly thought to be. He says, indeed, that during part of his journey, "scarcely a day passed without our seeing two or three lions, but, like the rest of the animal creation, they uniformly retreated when disturbed by the approach of man. However troublesome we found the intrusions of the feline race during the night, they seldom, at any other time, shewed the least disposition to molest us, unless we commenced hostilities." He, however, does justice to the terrors of the maned monarch when he says, "those who have seen the monarch of the forest in crippling captivity only, immured in a cage barely double his own length, with his sinews relaxed by confinement, have seen but the shadow of that animal which 'clears the desert with his rolling eye.'"

Fallow-deer shooting. FALLOW-DEER SHOOTING. There are only three kinds of deer in Great Britain; the red, the fallow, and the roe. The fallow deer, which was the dun deer of the days of Robin Hood, is the common deer of the parks. The positions of a stag at rest when fired at may be reduced to three, for each of which a different aim should be adopted. First, when presenting his side to the shooter, the aim should be low behind the shoulder. Secondly, when standing obliquely from the shooter, the aim should be just under the ear, which is a vital part; there is too the chance, when this aim is selected, of reaching the brain through the upper or back part of the cheek, or of striking the animal in some other part of the neck, which will generally bring him down or so disable him that he will be readily recovered. It may be observed here, that the quickest mode of dispatching a dog, horse, or any other domestic animal is to shoot them through the neck, just under the ear. Thirdly, when standing or moving directly from the shooter, the aim should be at the back of the head; thus a chance is secured, should the part aimed at not be struck, of lodging a ball in the neck or spine. When a deer is approaching the shooter, or standing with its head towards him, he should wait until he can have a cross, an oblique, or a driving shot. When a deer is wounded, however slightly, one or more dogs should be instantly slipped. The dogs for this purpose should, as far as practicable, com-

Shooting. bine the nose of the bloodhound with the speed of the greyhound. A kind of wiry-haired greyhound is used for this purpose in the Highlands.

Deer stalking. Deer Stalking. The red deer, which is larger, and the roe-buck, which is smaller than the fallow deer, are found chiefly in the uncultivated mountainous districts of the North. To destroy the deer of an adversary was once a mode of annoyance. Chevy Chase, it would seem, from the three first stanzas of the famous ballad of that name, was an expedition of this description:

> " To drive the deer with hound and horn,
> Earl Piercy took his way;
> The child may rue that was unborn,
> The hunting of that day.
>
> " The stout Earl of Northumberland,
> A vow to God did make,
> *His pleasure in the Scottish woods,*
> *Three summer's days to take,*
>
> " With fifteen hundred bowmen bold,
> All chosen men of might,
> Who knew full well in time of need,
> To aim their shafts aright."

The pursuit of deer with the rifle is termed deer-stalking. To kill the semi-domesticated fallow deer requires little skill beyond that possessed by a good marksman. The skill of the deer-stalker, in pursuit of the red deer, is not only dependant on a good use of the rifle, but is shewn in his ability to find and approach deer; to do which successfully requires the most unwearied perseverance. Many of the Scottish forests wherein the stalking of deer in their wild state is practised, are of immense extent. It is on such tracts of land as the forests of Mar and Athole that the red deer is sought. The forest of Athole alone is said to be more than forty miles long, and in one part eighteen broad, of which about 30,000 imperial acres are devoted to grouse, 50,000 partly to grouse and partly to deer, and there are reserved solely for deer-stalking 52,000 imperial acres. In these vast solitudes, the Highlander stalks the antlered monarchs of the herd, harts which, a century ago, bore the scars of the weapons of his ancestors. An old Celtic rhyme which has been thus Englished, shews the great age to which the deer and the eagle are supposed to arrive.

> Thrice the age of a dog is that of a horse;
> Thrice the age of a horse is that of a man;
> Thrice the age of a man is that of a deer;
> Thrice the age of a deer is that of an eagle.

So far as regards the age of the eagle, these lines contain an assertion which can neither be proved nor negatived. It is different as regards deer. There has long existed a custom of marking fauns that have been caught, and as each forester has a distinct mark known as his own, the age of a marked deer can generally be nearly ascertained.

The deer-stalker has recourse to a thousand manœuvres to approach a herd or solitary stag. The animals are usually descried at a long distance, either by the naked eye, or by the aid of an achromatic telescope, and the mode of approaching them entirely depends upon the situation in which they are discovered. Should it seem impracticable to steal upon them while at rest, the stalkers, armed with rifles, wait in the defiles through which the deer are expected to pass, whilst the attendants make a circuitous movement to get beyond the deer and drive them in the direction required. The deer-stalker, besides being an excellent shot, should have good judgment of ground and a hardy frame, combined with the patience and power to undergo extreme fatigue and privation.

When the red deer is fired at, he is usually at a considerable distance, and perhaps bounding away at full speed. Behind the shoulder, therefore, is the favourite mark. " In killing deer,"[1] says Mr. Maxwell, " it is necessary to select the head, or aim directly behind the shoulder. A body-wound may eventually destroy the animal, but the chances are that he will carry off the ball." Mr. Scrope,[2] whose experience and success in deer-stalking render his remarks valuable, says, " the most perfect shots and celebrated sportsmen never succeed in killing deer without practice; indeed, at first, they are quite sure to miss the fairest running shots. This arises, I think, from their firing at distances to which they have been wholly unaccustomed, and is no reflection upon their skill. It is seldom that you fire at a less distance than a hundred yards, and this is as near as you would wish to get. The usual range will be between this and two hundred yards, beyond which, as a general rule, I never think it prudent to fire, lest I should hit the wrong animal, though deer may be killed at a much greater distance. Now the sportsman who has been accustomed to shot guns, is apt to fire with the same sort of aim that he takes at a grouse or any other common game; thus he invariably fires behind the quarry; for he does not consider that the ball, having three, four, or perhaps five times the distance to travel that his shot has, will not arrive at its destination nearly so soon; consequently, in a cross shot, he must keep his rifle more in advance. The exact degree, as he well knows, will depend upon the pace and remoteness of the object. Deer go much faster than they appear to do, and their pace is not uniform, like the flying of a bird; but they pitch in running, and this pitch must be calculated upon."

The interest and anxiety attending this sport must be as intense as the pursuit is laborious. After climbing for hours the mountain side, with the torrent thundering down the granite crags above him, and tremendous chasms yawning beneath him, the stalker, with his glass, at length descries in some remote valley, a herd too distant for the naked eye. He now descends into the tremendous glen beneath, fords the stream, wades the morass, and by a circuitous route threads the most intricate ravines to avoid giving the deer the wind. Having arrived near the brow of the hill, on the other side of which he believes them to be, he approaches on hands and knees, or rather vermicularly, and his attendant, with a spare rifle, does the same. A moment of breathless suspense ensues. He may be within shot of the herd, or they may be many miles distant, for he has not had a glimpse of them since he first discovered them an hour ago. A moment, and the antlers appear; another, and the herd is in sight. Resting his rifle on the heather, he takes a cool shot at the finest hart, which falls; the rest bound away; a shot from the spare rifle follows, the " smack" of the ball is heard, and the glass tells that another noble hart must die. The dogs, which had been kept far back, are slipped, and are out of sight in a moment. The sportsman follows; he again climbs a considerable way up the heights; he applies the telescope, but nothing of life can he behold, except his few followers on the knolls around him. With his ear to the ground he listens, and amidst the roar of innumerable torrents, faintly hears the dogs baying the quarry, but sees them not; he moves on from hill to hill towards the sound, and eventually another shot makes the hart his own. The deer is then gralloched, and partially covered with peat; the horns are left upright, and a handkerchief is tied to them to mark the spot, that the attendants may find it at the close of the day. Let the reader imagine how much the interest of all this is enhanced by the majestic scenery of an immense, trackless, treeless forest, to which domesticated life is a stranger, where mountain, corrie, cairn,

Shooting. and glen, thrown promiscuously together, present the grandest of savage landscapes, which, as the field of wild adventure, cast into shade what Mr. Scrope calls "the tame and hedge-bound country of the south."

The Fowling-piece. THE FOWLING-PIECE. Before making choice of a gun, the shooter should determine what weight he can conveniently carry. The heaviest gun, as regards shooting, will be most effective, but he should recollect that unless he be a very robust person, a light gun will, on the whole, bring him more game, as a few additional pounds in the weight of a gun makes a deal of difference in the distance a person can travel in a day, and, moreover, he cannot shoot as well when fatigued.

The most approved guns under the system which prescribes a heavy charge of powder, and a light one of very small shot, are double barrels, weighing, according to the fancy of the shooter, from six to nine pounds, and bearing the following relative proportions of length to guage: fourteen guage, thirty-four inches long; seventeen guage, thirty-two inches long; twenty guage, thirty inches long. Taking the season throughout, we are convinced, that the most effective gun is a short, wide-bored one, each barrel being charged with rather less than $1\frac{1}{2}$ drams avoirdupois weight of powder, and full 2 oz. of No. 2 shot, containing 220 pellets. This is the general charge, but it may be varied according to circumstances. When game is wild, we would charge the reserve barrel, and, on some occasions, both barrels, with $2\frac{1}{2}$ drams of powder, and a No. 5 blue cartridge for partridges, and with a No. 4 or 5 red cartridge for grouse shooting. No. 7 shot is best for snipe shooting. Small shot may be used for partridge shooting in September, though we do not see any reason for not adhering to No. 2, except that birds very near the gun are liable to be more disfigured by it.

Barrels twenty-six or twenty-eight inches long, and fourteen or sixteen guage, are of convenient size. We think it will not be questioned that these barrels are as efficient as long narrow-bored ones for short distances, viz. under thirty-five yards, and nine-tenths of game brought to the bag is killed within that distance. And for making long shots, the wire-cartridge has obviated the necessity of using long guns. A most material advantage attending the use of a short gun is, the comparative ease with which it may be carried. A pound additional weight at the breech is not so fatiguing to the arm as half that weight added to the end of the barrel; it is the top-heavy gun that distresses the shooter.

Different proportions of powder and shot are required for different sizes of shot. The following may be the proper proportions for a gun not exceeding eight pounds:

Size of shot.	Weight of shot.	Weight of powder.
No.	oz.	drams.
2	2	$1\frac{4}{10}$
3	$1\frac{3}{4}$	$1\frac{1}{2}$
4	$1\frac{1}{2}$	$1\frac{3}{4}$
5	$1\frac{3}{8}$	2
6	$1\frac{1}{4}$	$2\frac{1}{4}$
7	$1\frac{1}{8}$	$2\frac{1}{2}$

These proportions cannot be materially deviated from without destroying the effect. If the powder is decreased, the discharge is weakened; if the powder is increased, the shot spreads; if the weight of shot is decreased, there will not be a sufficient number of pellets for effective shooting; if the weight of shot is increased, the discharge is weakened.

The usual objection to large shot is, that after it has travelled thirty yards it becomes dispersed; but let the powder be reduced to less than $1\frac{1}{2}$ dram, and that objection fails. If it is not overcharged with powder, a gun will shoot No. 2 shot close enough to kill at from thirty-five to fifty yards, with more certainty than if charged with small shot, and two or three drams of powder.

It is not so much the velocity as the momentum of a shot that renders it effective. The momentum of a shot increases in a direct ratio with its weight. The momentum of a No. 2 shot much more than compensates for the diminished weight of powder and additional weight of lead that we have recommended. Large shot droops more than small, and sooner comes to the ground, as it is not carried with the same velocity. It is the momentum, and not the velocity, that the shooter must look to.

We do not suppose that feathers or fur of game present any serious obstacle to either large or small shot; but if they did, the fact that large shot is most effective for shooting wild fowl armed with down, at once tells that it must be so for shooting game which is not so protected. Another advantage of large shot is, that when the aim taken is not quite correct, a single outside pellet will often bring down a bird, when it would require many small shots to do so.

The shooting of barrels depends mainly on three things, viz., the metal of which they are made, the boring, and the breeching. The quality of the metal is of much importance. All barrels expand when fired; and those made of inferior metal expand more than those made of stub-twist. Mr. Greener, in his excellent treatise on the "Gun,"[1] says, "that a barrel is a spring on an extended scale, and the more we can make it partake of the nature of a spring, the better. If we must have expansion, let us have it in its most beneficial form; an expansion that will aid the powder in expelling the lead. This cannot be entirely obtained, nor can the quantity of expansion be entirely destroyed, though you were to make your barrels of the weight of a twenty-four pounder. We must, therefore, decrease it, by making our iron as elastic and tenacious as possible. The qualities of elasticity and tenacity can only be obtained by hammer-hardening the iron. Barrels hammer-hardened will shoot as well without any artificial friction, as those whose friction is extreme, yet have not yet been benefited by the process."

The term friction implies a gradual contraction of the barrel towards the muzzle, which retards the progress of the shot, that more time may be allowed to the powder to burn. "The shooting of all barrels," says Mr. Greener, "depends on a certain degree of friction. The degree of friction necessary varies according to the nature and substance of the metal. Those metals that require least shoot best. The object of the friction is to create a greater force, by detaining the charge longer in the barrel. If, then, there should not be an extra quantity of powder to consume, the friction would be a decided evil." A greater degree of friction is generally allowed to a short barrel than to a long one. A gradual expansion of the barrel towards the muzzle is termed relief. Relief accelerates the progress of shot through the barrels. What is the proper degree of relief or friction for different descriptions of barrels, is a subject fruitful of much controversy; as is also the form of the breech. The best breech is that which will cause the greatest quantity of powder to consume in the barrel.

Mr. Greener would not prevent the barrel expanding when fired, by increasing its thickness, but by improving the quality of the metal. When the barrel expands much, or is held loosely when fired, a loss of strength is induced, as that power which, if possible, should be exerted on the shot, is uselessly expended in a contrary direction, whereas, when the barrel is firmly fixed, and made of metal that only

[1] The Gun, by William Greener. London, 1835.

expands in a trifling degree, or, as Mr. Greener observes, operates as a spring, that portion of the explosive force which strikes in any direction, except against the shot, is forced back, or rebounds upon the shot, and consequently becomes a portion of the available strength of the charge. Much of the force that is thrown on a solid fixed surface is returned, but not that which is expended on an yielding one.

Mr. Greener shews that much loss of strength is induced by barrels not being firmly held when fired; and argues that the mode of proving barrels by allowing them to fly back into sand is defective, as, by reason of the projectiles giving way in one direction and the barrels in the other at the same time, there is not a sufficient strain on the barrels to prove them effectively. On this subject he says, " Let any one take his gun and load it as usual; suspend it by two ropes so as it can fly back; place a quire of brown paper as directly in front of it as possible; fire it, by squeezing the trigger and the back side of the guard together, so as not to displace the gun; examine the impression the shot has made in the paper. If they have stuck in at the distance of forty yards, they have done well. Load again, and fire from the shoulder, and you will find the shots driven through a great number of the sheets. Load again, but first take the barrels from the stock, lest you should happen to break your stock, as I have seen done by a gentleman placing his gun on a stone wall; while he rested, the gun by accident went off and shivered the stock into many pieces, and severely cut his hand by the splintering. (So severe is the recoil from a gun on being fired, when resisted by a solid, unyielding substance. When fired from the shoulder it is different, as the body yields to the recoil, and thus prevents that which would inevitably be inflicted, if the shoulder were placed against a solid substance.) Secure the barrels on a piece of wood, and behind place anything firm; for instance, a piece of lead sufficiently heavy, and that will not injure the end of the breeches, technically called the buts, when they strike it. Having secured them perfectly, fire the barrel in any way you can, and then examine the force of the shots in the paper, and if you do not find that they have penetrated further than they did when fired from the shoulder, say my doctrine is false. It follows, as a matter of course, from these experiments, that in shooting, the more firmly a gun is held to the shoulder, the better it will shoot.

" It is upon these experiments that I found my objections to the practice of allowing best barrels, when proved, to fly back into sand. Such a mode of proof is of no use. Were they fixed like common barrels, the force of the proof would be increased one-half. I doubt whether the present method be any test at all. I am satisfied that the force exerted in this mode of proof on the barrel, is not equal to the pressure of a large sporting charge, when fired from the shoulder.

" The fact that the shooting powers of a gun are increased by its being fixed in an immoveable frame, is proved with the practice of mortars. Mortars on iron beds, and these firmly embedded in the earth, will throw a shell farther when on the ground, than when placed on a platform, or on board a ship. It is for the purpose of destroying the recoil, that mortars for sea-service, though of the same calibre as those intended for land-service, are made three times the weight. Dr. Hutton states, that he found no advantage by retarding the recoil in practice with artillery. He means, that no advantage is gained by stopping at three feet a gun accustomed to recoil to the distance of six. The statement is perfectly true. If he were to allow a gun to recoil only an inch, and then strike against a solid substance, he would gain nothing. For if it recoil ever so little, the shooting force is as much weakened as if it recoiled twice as far.

" To increase that force, a steady fixed resistance is required. The velocity of the projectile depends on the force of the immediate impulse. Before a gun, suffered to recoil, could rebound from striking some solid substance in its recoil, the charge would be gone, and could, therefore, receive no additional impetus from that rebound. The truth of this fact may be illustrated by throwing a hand-ball against any loose body with sufficient force to displace it. However hard or elastic that body might be, the ball would not rebound from it, but would fall perpendicularly down. Fix and secure that same body, and then the ball will rebound with little less force than that with which it was thrown against it. So it is with gunpowder. If it meet with a firm resistance, it will rebound and project the ball or shot with additional force."

On Charging the Fowling-piece. It may be premised that all powder, before being put into the barrel, is more or less damp; and most barrels, especially if they have been only imperfectly cleaned, or have been fired and laid by since being cleaned, are also more or less liable to damp. A portion, therefore, of powder should be flashed off in each barrel immediately before charging, for the triple purpose of expelling damp, proving whether the passage through the pivots on which the caps are to be placed, is open, and warming the barrels, so that any little moisture in the charge of powder may be absorbed. The barrels are then held perpendicularly and the powder poured in, in such manner that the whole charge may reach the bottom; and a wadding is then pressed down upon it. The shot is next poured in and another wadding pressed upon it. The shooter next removes the remains of the caps, and looks whether the powder has found its way to the orifice of the pivots, and if it has, he places fresh caps on. If the powder is not visible at the orifice of the pivots, he removes any obstacle with a pen-knife or pricker, and contrives to push down a few grains of powder.

Wire-cartridges.

Wire-Cartridges. The wire-cartridge (fig. 1.) was invented in 1828 by Mr. Jenour. It consists of a cylindrical case or net-work of wire, the meshes of which are somewhat more than an eighth of an inch square; at the lower end the wire partially closes; the wire case is then enveloped in fine paper, and at the upper end a cork wadding, cut so as to fit the guage of the gun, is affixed; the case is then filled with shot and bone dust. The first cartridges made, though ingenious in construction, were defective in operation. It was a matter of no ordinary difficulty to fabricate them in such a manner that the shot should leave the case at the precise distance required. This at first, could not be done so that they might be trusted in every instance. Every alternate cartridge might fire well; but the rest would fire irregularly, being liable to ball; that is, the shot would not leave the case until fifty or sixty yards from the gun, and such cartridges were, of course, not only useless but dangerous. They have been from time to time improved, and almost every difficulty has been overcome. The sporting cartridges now made never ball; they act with a considerable degree of precision and certainty; and that they may be safely trusted may be inferred from the fact that they are often preferred by persons engaged in pigeon matches. Various materials were used experimentally to fill up the interstices between the pellets, but nothing seems to answer so well as the material now used. Another difficulty in their construction presented itself. It was requisite to accommodate them to the various methods of boring pursued by different gunmakers, and the unequal length of barrels, the object in view being to produce a cartridge that would suit all barrels of the same guage; and this has been, in a great measure, if not wholly, accomplished. The liability to ball which, notwith-

Fig. 1.

Shooting. standing various improvements made in them, was not effectually obviated for many years, during which they were tried, and in many instances prematurely condemned, either from real defects, or from the parties not knowing how to use them. They were not brought to perfection until the year 1837.

The wire-cartridges possess two principal advantages over loose shot; they are propelled with greater velocity, and thrown more evenly. A loose charge is always thrown in patches; the shots of a cartridge, as seen on a target, are comparatively equi-distant from each other. There are four classes of wire-cartridges, which the patentees have named the *battue*, the *blue*, the *red*, and the *green;* each intended for a different range. There is some little difference in the construction of each of the three kinds; the meshes of the frame-work are larger in the battue and the blue than in the red, and in the red than in the green, and there are doubtless other differences not perceptible to the uninitiated. The battue and the blue cartridges are intended for general use; the battue for the shortest distance; the blues will kill several yards further than loose shot of the same size, and of the four kinds, are, in our opinion, decidedly to be preferred; each blue cartridge being thrown more nearly alike, they are more certain in their operation than the red and the green, which are intended for longer distances. The red may be serviceable in open places, when game is wild, and the shooter is provided with a gun of not less than fourteen guage, or with a very short barrel, which does not throw its shot very strongly. The green cartridges are intended chiefly for wild-fowl shooting; these should be used in barrels of not less than twelve guage. The red and green cartridges retain the shot in the case longer than the others, and are carried with an astonishing force to an incredible distance, and at the same time very closely. The red may generally be trusted for long distances, especially from barrels of large calibre; but at short distances the smallness of the circle they describe renders them objectionable. The green cartridges should never be used for shooting game. The blue and battue only should be used in barrels of small guage.

The wire-cartridges do not require either a greater or less charge of powder than loose shot, but there is this peculiarity attending them. A heavy charge of powder throws the shot from the cartridge more closely than a small charge, by reason of its allowing more time for the escape of shot from the net-work. This is exactly the reverse of the manner in which the loose charge acts. The greater the charge of powder when loose shot and wadding are used, the more is the shot dispersed, and *vice versâ*. Either loose shot or cartridge shot is projected with greater force and velocity when a heavy charge of powder is used. When birds lie well, we would recommend the shooter who adopts the cartridge to charge lightly with powder, to give the shots time to spread well; when moderately wild, we would charge lightly with powder in the first barrel, and heavily in the reserve barrel; but when birds are very wild, both barrels should be charged with as much powder as the shoulder can conveniently bear, so as to give the charge the greatest possible force, and at the same time the greatest practicable degree of closeness. It is at long distances that the superiority of the cartridge is conspicuous; when the loose charge is used, the increase of force that is obtained by loading heavily only tends to dispersing the shot, thereby rendering the increased momentum of little avail.

Amongst the advantages attending the adoption of wire-cartridges, it may be mentioned, that the recoil is not so severe, and consequently a lighter gun may be used, than with the loose charge, and this is a great relief to the shooter in a heavy country, and especially on the hills in August, when the heat of the sun is frequently overpowering. The cartridges act well when fired from short barrels, perhaps more satisfactorily than when fired from long ones. The increased facility and expedition of loading is another advantage which should not be overlooked. Shooting.

The main objection to wire-cartridges, and it is a material one to a person who is an indifferent marksman, is, that they do not describe a sufficient circle at short distances. When game is wild they are invaluable for the reserve barrel of a double gun.

The wire-cartridges usually kept on sale contain, for the different guages, the following weight of shot.

Calibre.	Weight of shot.	Calibre.	Weight of shot.
20	$\frac{7}{8}$ oz.	14	$1\frac{1}{4}$ oz.
19	1	13	$1\frac{3}{8}$
18	1	12	$1\frac{3}{8}$
17	1	11	$1\frac{1}{2}$
16	$1\frac{1}{8}$	10	$1\frac{3}{4}$
15	$1\frac{1}{4}$		

When ordering cartridges, it is necessary to give the *guage* of the barrel, the *weight* of the cartridge, the *size* of shot, and the *description*; that is, whether battue, blue, red, or green.

The green cartridges, fired from a common-sized fowling-piece, are not to be depended upon for any distance nearer than fifty yards; and, for that reason, they should only be used for wild-fowl shooting, for which sport they may answer very well when fired from a reserve barrel. We would not recommend their adoption, even for wild-fowl shooting, to a person using a common-sized single gun, since by so doing he would hazard missing when the most favourable opportunities of killing presented themselves. A No. 3 red cartridge would suit better.

The wire-cartridge has been proved to be much superior to the loose charge for the stanchion, and heavy shoulder guns used on the sea-coast and rivers. For the largest shoulder guns, B or B B loose shot, or a No. 1 cartridge is usually adopted. A A loose shot, or a B or No. 1 cartridge will better suit the stanchion gun.

Taking aim.

Taking Aim. As the manner of taking aim is a matter of primary importance to success in shooting, a few observations on that head may not be misplaced here. When the dog points, or when birds rise near to him, the shooter should immediately draw back both hammers with the right thumb;[1] but should the birds rise at a considerable distance, to save time he need only cock one barrel, as in this case, he has only to fire once. He should never be in haste. It is more prudent to let the bird escape than to fire hastily. If on open ground, he should not fire until the bird is at least twenty-five paces distant, by which means he avoids, on the one hand, the hazard of mangling it, and, on the other, a probability of missing; for at the distance of from twenty-five to thirty yards, whether the piece be charged with loose shot or the wire-cartridges, the range of the whole charge will be wide, yet the pellets will be so close together that nothing can escape, if the aim be true, and, what is of no less moment, the finger also obedient to the eye. He should be deliberate in bringing up the piece to his shoulder, and in making it to bear on the object, but the moment he has brought it to bear, the finger should act in co-operation with the eye, the eye being kept open the while, so that

[1] Many experienced sportsmen disapprove of the practice of cocking both barrels at the same time. They think that it ought to be a rule never to cock either barrel, until the game be upon the wing, then that the left barrel should be cocked and fired, and thereafter taken from the shoulder. The right barrel should then be cocked and fired if necessary; if not discharged, it should be put back to the half cock, and the left re-loaded.

Shooting. the shooter may see whether the bird falls, or feathers fly from it; for if he does not, he may rely that there is something defective in his system of managing the fowling-piece. A shooter only requires coolness, a very little mechanical knowledge, and a gun properly mounted. Possessing these requisites, he will not be deficient in any other which he will not be easily able to supply. The novice should learn to shoot high enough at winged, and low enough at footed game, and well forward at both. He should seldom shoot directly at the object; but at the wing, if the bird is moving obliquely from him, the head, if the bird is rising, the legs, if descending; but if crossing, or flying obliquely at a considerable angle, he should make an allowance of a few inches, according to the distance of the object from him. It is not usual, except in the cases of blackcock, to shoot at any object approaching the shooter. It should be allowed to pass, when he turns round and fires at it as it moves from him.

The Rook. *The Rook.* We commence our notice of the different kinds of shooting with the fowling-piece now chiefly practised, with a few observations on those birds, not coming under the denomination of game, which occasionally afford the first lessons to the younger brethren of the trigger, and which therefore may properly take precedence, in description, of the more difficult branches of the art.

Young rooks, in the month of May, are generally shot whilst sitting on the branches, near their nests, on the tops of the loftiest trees, so that it requires a steady aim, and hard-stricken shot to bring them down with certainty; for if only wounded, they will frequently cling to the bough with their claws, and die suspended in that manner. The rook should be fired at with a small charge of rather large shot, and a heavy charge of powder. Rooks are gregarious, and feed on grain, worms, and insects. It is only during the season of incubation, and until the young ones can fly, that they frequent the rookery, which is mostly a small plantation, or clump of old trees, and near to some habitation. When rooks choose any particular cluster of trees, or plantation to build in, the same trees will, if standing, be tenanted again the next year by the same rooks and their offspring. notwithstanding they may have been much fired at, or in some other way disturbed. This opinion is not universal. In some counties there exists a prejudice against the practice of firing at rooks with gunpowder, especially when the rooks are few, and the number of trees limited, lest the rooks should desert the rookery; and, therefore, that as little alarm as possible may be created, they are fired at with balls from the air-gun, and sometimes the young shooter will try his skill with the cross-bow. The old rook is distinguished from the young one by the thick end of either mandible being white; and the beak of the young rook is black to the insertion. They are distinguished from other birds of a somewhat similar appearance, by a slight variation of colour; the rook has a blue, the carrion-crow a brown tinge, the jackdaw is partially grey, the raven is jet black.

After young rooks have been fired at several times, some of the strongest and best-fledged will quit the rookery, and alight on hedges or trees at some distance, where the shooter flushes them, and they afford good sport to the tyro learning to shoot birds on the wing. A warm sunny day is best for rook-shooting. In cold weather, particularly on windy days, young rooks will not quit their nests.

The Wood-pigeon. *The Wood-pigeon.* The wood-pigeon is little regarded by the sportsman. A shot may be obtained by lying in ambush early in the morning, near to some wheat stubble, or field of newly-sown grain, where the birds feed; but the best sport the wood-pigeon affords is at the roosting places, where the shooter ought to take his station an hour before sunset. It is difficult to obtain a shot in any other manner, except when the birds are young, when they are sometimes killed in trees, in the same manner as young rooks. The shooter in pursuit of game often sees them, but rarely obtains a shot at them. Sometimes, but it is usually when he is not aware of them, they will suffer him to approach close to the tree in which they are perched. The tree is generally a large one, and perhaps in full foliage, and the shooter hears the rustling of the wings of the decamping birds, but seldom secures a shot. Whenever a wood-pigeon leaves a tree, the shooter should prepare for others, since, when there are several in the same tree, they will not leave it simultaneously, but move off in succession. They are large strong birds, and require heavy shot to bring them down.

Shooting tame pigeons is becoming a very common amusement; but it is oftener practised to decide a wager, than prove the skill of the parties. The Red House at Battersea, near London, is the scene of the principal matches. The birds are sprung from a trap, which is usually placed twenty-one yards from the gun; the birds of each person are provided by his opponent; blue rocks are the favourites; very heavy guns are used, but the weight of shot is usually limited. The birds must fall within a limited distance from the trap, or they are not counted amongst the successful shots.

The Lark, &c. *The lark, field-fare, lapwing, golden plover, and dottrel.* Larks and field-fares are often the object of the young shooter's pursuit. Field-fares, the blue-backs and red-wings, arrive in October, and remain during winter. They are easily approached during a frost, or when the ground is covered with snow. They will then be found in search of the berries of the mountain-ash, the holly, and the hawthorn, and are killed in great numbers. Like wood-pigeons, field-fares do not leave a tree, or rise from the ground simultaneously, so that when one bird flies off, if the shooter will hasten to the spot, he will, in all probability, meet with a lagger.

The lapwing or pewit is a bird much sought for by the juvenile shooter. Lapwings are commonly found on marshes, or wet land abounding in rushes. Except during the season of incubation, they collect in flocks, and are so very wary as to be difficult of approach. They are often killed for the sake of their toppings, which are useful to the angler. As they wing round the shooter, it is extremely difficult to decide whether they are within range or not; they should be within a moderate distance when fired at, or they will escape in the interstices of the charge, as the size of the body bears a small proportion to the apparent size of the bird when on the wing. It is not uncommon to see several feathers cut out of the wings, and the bird fly away as if unhurt.

All these birds afford amusement chiefly to schoolboys. The sportsman in pursuit of game does not think them worthy attention; but the golden or whistling plover, and the dottrel, which are birds often met with in hilly districts, are generally considered as worth firing at, if they accidentally come in the way, but are not worth the trouble of following.

The Land-rail. *The Land-rail.* The land-rail or corn-crake is a bird of passage. It may be found with pointers or spaniels early in spring, in hedges or long grass. The dogs for this sport should not be staunch; such as will foot the birds are best as it is with great difficulty they can be made to rise. It is only during the first fortnight after their arrival that they may be fairly killed in spring; after that time they begin to pair. In August and September, the sportsman sometimes casually meets with a land-rail, whilst beating for other birds.

Wild-fowl. Wild-fowl. Wild-fowl shooting is practised in various ways. The method of proceeding depends entirely on the situation in which the shooter expects to find the birds. In some of the inland counties, except during hard frosts, they are not met with anywhere but on large pools and ri-

Shooting. vers, and are only to be approached by having recourse to some stratagem, as waiting in a shed, or on an island, or on the banks of a pool, or stalking behind a horse trained to the purpose. The largest shoulder gun that is at hand may be used charged with the red or green wire-cartridges, the size of shot being regulated by the bore of the piece.

During a severe frost, wild-fowl are compelled to leave the pools, and are then found in small rivers, brooks, or in drains where there are springs of fresh water. The flights being broken, ducks are found singly or only few in number, and are consequently easy of access, and may be shot with a common fowling-piece. The size of shot should be No. 2, or 3. Wild-fowl are so fortified with down on some parts as to resist any but hard-stricken shot. Their back is the most vulnerable part, and all kinds of wild-fowl present it to the shooter as they rise. They are also easily brought down when they present a cross shot; but when approaching it is not advisable to fire at them. If a dog accompany the shooter, it should follow at heel. As the shooter pursues the course of a river or brook, he should keep out of sight as much as possible, and come suddenly on every turn or winding. When there is a mist during a frost, wild ducks will remain in the brooks and gutters all day. The earlier in the morning the better for this sport. Ducks may also be killed on the wing, on the verge of night, by the shooter lying hid near to fresh water springs. If it be a dark evening, he need only wait about a quarter of an hour, but if moonlight he may wait about an hour. They may also be walked up on a moonlight night, when, if they rise above the horizon, they may be killed almost as easily as in the day time. The objection to night shooting is, that birds knocked down are often lost. These are the principal methods by which ducks are killed by any but professed wild-fowl shooters.

The larger kinds of wild-fowl, such as hoopers *(wild swans)* and geese, can rarely be brought down by the common fowling-piece, unless struck on the head or back. Wild-fowl shooting, in creeks and harbours on the sea-coast, is conducted in a very different manner, and on a larger scale of operations. There are two kinds of guns used for the purpose, the shoulder-gun and the punt-gun; the latter being fired from a rest, or frame, or carriage, either in a boat or some other floating craft. Mr. Greener, to whose work we have already referred, says, "Never make duck guns (shoulder-guns) above seven-eighths in the bore, if you wish them to kill at a great distance, and not less than fifteen or sixteen pounds weight, and full four feet long." Colonel Hawker,[1] who has devoted nearly one hundred and fifty pages to the subject of wild-fowl shooting, says, "The barrel of a punt-gun, to be in good proportion, should, I conceive, (including the patent plug, of about six pounds weight, and from two to three inches in length), be about seventy or eighty pounds weight, from seven to nine feet long, and from an inch and a quarter to an inch and a half bore, according to the one length and weight, or the other. The smaller the bore is, in reason, the further you can kill at a small number of birds; but the larger size of these two shoots the best, and is the most regular pattern. Any thing beyond that size seldom answers." Both these writers seem to agree that the common punt-gun, though it weigh eighty or one hundred pounds, cannot be charged to the extent of its shooting powers, by reason of the tremendous recoil that would result; but each advises that the additional weight should be gained by using the barrels double. Thus more than a double advantage would be secured, for not only would there be two barrels at command, but the discharge from each barrel would be more effective. The charge of shot for a punt-gun averages from ten to twenty ounces; the shot is much larger than any used for shooting game. Shooting.

The Colonel, and we apprehend he is the only practical writer on this department of the subject, describes the various kinds of punts (which are flat-bottomed boats or canoes, so constructed as to be manageable either on sands, or in mud, or water,) used in several different counties, and gives the following directions for shooting wild-fowl, from a punt, with a large shoulder-gun. "Sit down on some straw or rushes, with your gun by your side, and take with you a small Newfoundland dog. Row about, till you can see or hear a flock of wild-fowl on the mud. To find them sitting, if by night, look at first very low, so as to bring the surface of the mud in contrast with the horizon, by which means you will overlook the black edges of the creeks and holes, instead of seeing, and perhaps mistaking them for birds.

"When you have rowed within two or three gun-shots of the fowl, take in your oars, and reconnoitre the creeks. Having ascertained which is likely to be the best, lie down, and push along with the *setting pole* or *gunning spread,* and while the mud banks stand above the little channels, you are so completely hid, that you will seldom fail to get a shot, provided there is a creek within reach of the birds, and you do not go directly to windward of them.

"On arriving sufficiently near, should the water be so low that you cannot present your gun at the birds without kneeling or standing up, you must get aground at the side of the creek, or steady your canoe by means of forcing each oar from between the *thowls* into the mud, otherwise the recoil of the gun will set her rocking, and thus you might probably be tipped out. Having made all fast, rise up and fire. Take care, however, to rise high enough to be well clear of the mud, or not a feather will you touch; and present as follows: By day, or moonlight, if the birds are close, directly at them; or if beyond forty yards, shoot at their heads; unless they are feeding in a concave place, where the tide has left a kind of plash, in which case you must level rather under them, or you will only graze their back feathers. In star-light, take your aim just at the top of the narrow black line, in which birds always appear to one who is low down; and when so dark that you cannot see your gun, present, as you think, about a foot over, or you will most likely shoot above a foot under them.

"Should you have been successful, you will, if at night, generally hear your cripples (wounded fowl) beating on the mud, before you can sufficiently recover your eyes, from being dazzled by the fire, to see them. Your man then puts on his mud-boards, (which are flat square pieces of wood fastened to the feet, to enable the party to walk or wade through mud), taking the setting pole to support him, and assist the dog in collecting the killed and wounded; taking care to secure first the outside birds, lest they should escape to a creek. During this time you are left in charge of the punt; and should, if possible, keep a look out, in order to see if any more birds fall dead or wounded from the company, before they have flown out of sight.

"The gunner generally calculates on bringing home the half only of what he shoots, from the difficulty of catching the whole of his winged birds, which he calls *cripples,* and those that (to use the pigeon phrase) fall out of bounds, which he calls *droppers.* If the birds fly up, he generally declines firing, knowing that the moment they are on the wing, they become so much more spread, that he could seldom get more than three or four, for which it would be hardly worth while to disturb the mud; particularly as

[1] Instructions to Young Sportsmen. Eighth edition. London, 1838.

widgeon, by night, if not fired at, will, in cold weather, probably settle again at no great distance.

"In following wild-fowl, it is easier to get within twenty yards of them by going to leeward, than a hundred and fifty if directly to windward, so very acute is their sense of smelling.

"The best time, therefore, to have sport with a canoe and a shoulder-gun, (provided it be low water, or half ebb, while you are hid in the creeks), is in clear, frosty, moonlight nights, when the wind happens to blow towards you as you face the moon. It is then impossible for the wild-fowl to smell you; and you may, by getting them directly under the light, have the most accurate outline of every bird, and even distinctly see them walking about, at a much greater distance than a gun would do execution. From thus being on the shining mud-banks, they appear quite black, except some of the old cock widgeons, on the wings of which the white is often plainly to be seen.

"It does not follow, however, that nothing can be done without a bright moon. So far from it, that some of the best shoulder-gunners in the kingdom prefer but very little moon, even for the mud. Here, by constant habit, they can easily distinguish the black phalanxes of widgeons from the shades on the places they frequent, and particularly if they are feeding among the puddles which have been left by the tide. In this pursuit, and when not favoured by the best of light, there are a few cautions to be given to an inexperienced shooter. First, to ascertain that the black patch to be seen *is* a flock of birds, which he will do, by observing the occasional change of feature in the outside of it. Secondly, on approaching them, to be careful that their enormous masses and tremendous noise do not deceive him in the distance, and tempt him to fire out of shot. And, thirdly, not to be too eager in getting his dead birds, as it sometimes happens, in hard weather, that the remainder of the flock will again pitch down among them, particularly if he has winged some of the younger birds, which have not the cunning to make off for a creek, like the old ones. In this case, a reserved gun would, probably, more than double the produce of his first shot. It should be understood, that this night shooting is chiefly at the widgeon, as the geese, of late years, (since there have been so many shooters), have seldom ventured much in harbour by night, except sometimes at high spring tides, with a full moon; and the greater part of the ducks, teal, dunbirds, and such like, repair inland to the ponds and fresh springs, unless driven to the salt feeding ground by severe frost.

"A company of widgeons, when first collecting, may be heard at an immense distance, by the whistling of the cocks and purring noise of the hens; but when they are quietly settled, and busy at feed, you sometimes can only hear the motion of their bills, which is similar to that of tame ducks."

Geese, ducks, widgeons, hoopers, curlews, and other wild-fowl, are killed in this manner; but the most destructive method of killing them is with the heavy stanchion or swivel punt-gun, used by the persons on the coast who make a trade of wild-fowl shooting. When a fair shot can be obtained by this method, from twenty to fifty birds may be killed at one discharge; but it is laborious, wearisome work, and, except for a single occasion, can scarcely be called sport. This kind of shooting is carried on in the night, usually in frosty weather, at which time sailing about on water, or working the canoe through mud, cannot be accompanied with very agreeable sensations.

The size of shot for punt-shooting should, in some measure, be regulated by the size of the birds expected to be met with, and their degree of tameness; yet it is well to be prepared with shot of sufficient size, as hoopers, geese, and other large birds, are sometimes found when least expected.

The Water-hen, &c.—There are various kinds of wild-fowl, which will dive rather than fly away when disturbed. They are, for the most part, clumsy birds on the wing, and are killed without difficulty when they can be made to rise. When shot at swimming, the shooter takes aim, and fires instantaneously, or they will be under water whilst he is drawing the trigger.

Dogs.

Sporting Dogs. Before noticing the different kinds of game which are the object of the shooter's pursuit, a few observations on sporting dogs may not be irrelevant. The shooter's dogs are of four kinds; the pointer, setter, spaniel, and retriever.

Pointers and setters.

Pointers and Setters. If dogs were unknown in Europe, and some traveller from a distant part of the southern hemisphere were to relate that he had seen a new species of quadruped with wonderfully fine olfactory nerves, by the aid of which it was enabled to hunt to death the hare, stag, fox, or jackal, the tale would readily be credited; for the instinct of the hound, as compared with that of other animals, is not such as to excite surprise. But were the traveller to relate that he had seen a quadruped which, untaught, would stand motionless, as if converted into a statue, on coming in contact with the slightest scent of game, he would not be believed; it would appear incredible, such is the extraordinary instinct of the pointer and setter. We use the term *extraordinary* advisedly. There are other animals, and indeed other dogs, which possess a degree of instinct more nearly approaching to reason, but none possessing so extraordinary an instinct, an instinct not analogous to that of any other living creature that we are aware of. The pointer seems to be endued with it for the artificial service of man; whereas the instincts of all other animals are conducive to the supply of their individual wants, and their usefulness to man is secondary thereto. It would be difficult to controvert the argument that this instinct was given to the pointer for the purpose of aiding men to capture or kill game, by means of such engines as nets or guns. This, we are aware, may be a doubtful position to maintain; but who can say for what other apparent purpose this peculiar faculty was given? It may, indeed, be urged, that the propensity to point, in the pointer, is a means ordained by providence for his subsistence in a wild state, by enabling him to approach within reach of his prey, and thus to accomplish, by another species of stealth, what the tiger and other animals of the cat tribe effect by ambuscade. Such an argument, however, is presumptively rebutted by the fact, that all existing races of wild dogs are gregarious, and resort to the chase for food; nor is there any record of the existence of dogs in a state of nature, except those calculated for the chase. It is therefore gratuitous to assert, that the instinct or faculty of pointing was bestowed upon the pointer as a means of subsistence, since he has ever been dependant on man for food.

It is strongly argued, that all dogs have descended from one common stock, and that by difference in food, climate, and training, they have become what they are at present; nor is it more improbable that such is the fact, than that the human race are descended from one common parent; for dogs are not more dissimilar than the various tribes of men, who differ not only in outward form, but morally and intellectually, as much as dogs vary in size, shape, temper, and sagacity. Those animals which can be domesticated improve by acquaintance with man, as the wild fruits by cultivation. All wild dogs have some qualities in common; but their instincts are somewhat limited, or not called forth. It is only in its domesticated state that we find the various qualities which render the dog so useful a servant to man. Wild dogs are, in comparison with domesticated dogs, what savages (for wherever they have been found, savages bear some resemblance to each other, and are engaged in similar pursuits) are to civilized society. It

is inconceivable that the mastiff, terrier, cur, and numberless other dogs besides the pointer, could ever have been in a wild state, as they do not seem to be possessed of any instincts or faculties that could enable them to subsist unattached to the human race.

The long received opinion that the lion, as the king of brutes, is possessed of the highest degree of physical courage, is exploded. The palm of courage is now awarded to the dog. Courage, however, in the common acceptation of the term, is not a characteristic trait of the pointer or setter, which are, perhaps, except the cur, the least courageous of the canine race. The dog is the only brute animal that prefers the society of man to that of its own species; and no dog is more affectionate or faithful to man than the pointer or the setter.

England is not less famous for its horses than for its sporting dogs. Our grey-hounds, fox-hounds, and harriers are unequalled, and that they are so results from the care that has been taken to keep each species distinct. All our pointers are, in some degree, of Spanish extraction; and such of them as have most Spanish blood in their veins are unquestionably the best. The Spanish pointer is about twenty-one inches in height. He has a large head, is heavily made, broad-chested, stout-limbed, with a large dew-lap; his eyes are full, and widely apart, and his nose is broad; his tail is straight, short, and thick, and his ears large, pendulous, and fine; he should have a round, and not a flat foot. When pointing, he stands on three legs, one of the fore legs being raised, and his face and tail are in a line with his back. This is his invariable position when he comes gradually upon the scent; but whenever, by running with the wind, or from any other circumstance, he comes suddenly upon game, he will stand in the most picturesque and sometimes indeed grotesque attitude, frequently with his body almost doubled. A pointer may be sometimes seen standing with all four feet collected together on the surface of a small stone on a wall when the birds are almost under him. A very old dog of this description, when fatigued with ranging and too enfeebled to maintain his point long in the natural position, will sit down on his haunches with his face towards the game, yet ever and anon turning his head wistfully to see whether the gun be approaching. Notwithstanding however the vaunted excellence of British pointers, the generality of them are not such as they ought to be. It is much to be lamented that the same care is not taken in the breeding of pointers and setters as of hounds. Scarcely two pointers are to be seen so much alike that a naturalist would pronounce them to belong to the same class of dogs, inasmuch as they are dissimilar in size, weight, and appearance. There are, properly speaking, but two classes, the Spaniard and the mongrel. Nearly all the pointers we see are, in fact, mongrels, although each may have more or less of the original Spanish blood. Such, however, is the force of nature that a dog having in him very little of the blood of the pointer may prove a very serviceable dog to the shooter. We frequently meet with very good dogs, dogs deemed by their owners first-rate, which bear little resemblance, in point of shape and appearance, to the true pointer. Some have the sharp nose of the fox, others the snubbed nose of the bull-dog; some are slenderly formed; some long-legged, others short-legged; some heavy-bodied, others light; in short, there is every possible diversity.

The attempt to lay down a written rule whereby to distinguish between a good and an indifferent pointer would be futile. How much of the blood of the pointer a dog has in him will be read in his countenance, rather than inferred from his general shape and appearance. There is an indescribable something in the countenance of a thorough-bred or nearly thorough-bred pointer, which a little habit of observation will enable the sportsman to detect with tolerable accuracy, so that he may judge of the capabilities of a dog, as a physiognomist will read at a glance a person's disposition and ability in his countenance. It is to the disciplined eye only that these all but infallible tokens are discernible.

The instinct of pointing, we apprehend, is an inextinguishable and indestructible principle in the blood of the pointer, which, however it may be mingled with inferior blood, will always, in some degree, manifest itself; and on this ground we build our theory that the further any dog is removed from the original Spanish pointer the worse the dog is; and, consequently, that all attempts to cross the pointer with any other blood must necessarily deteriorate the breed. The grey-hound is seldom or never crossed to give him additional fleetness, nor the hound to improve his nose; why then should the pointer be crossed with dogs which, in so far as the sports of the field are concerned, scarcely inherit one quality in common with him? Attempts, however, are constantly made to improve the pointer by a cross with the blood-hound, fox-hound, Newfoundland dog, or mastiff, sometimes with a view of improving his appearance, and bringing him to some fancied standard of perfection; but in reality inducing a deformity. One of these imaginary standards of perfection is, that to one part thorough Spanish blood, the pointer should have in him an eighth of the fox-hound, and a sixteenth of the blood-hound. A cross will sometimes produce dogs which are, to some eyes, the *beau idéal* of beauty; but however handsome such dogs may be, they will necessarily possess some quality not belonging to the pointer; for instance, a cross with the hound gives the propensity to trace hares, if not to give tongue. A thorough-bred pointer carries his head well up when ranging; he will not give tongue, nor has he much desire to chase footed game. The hound pointer may be sometimes detected by his coarse ears, by his tail being curled upwards, and being carried high, or by his rough coat. An occasional cross with the mastiff or Newfoundland dog is said to increase the fineness of nose, but it is converting the pointer into a mere retriever. The pointer, as we before observed, is naturally cowardly, as compared with other dogs; therefore, whenever a pointer is ferocious or courageous, it may be inferred that the blood of some of the larger or stronger dogs runs in his veins. Another and the main source of the unsightliness of sporting dogs is the allowing an indiscriminate intercourse between pointers and setters. Good dogs may be thus obtained sometimes, but they are invariably misshapen; they have generally the head and brush tail of the setter, with the body of the pointer, and their coats are not sleek, and instead of standing at their point, they will crouch. When the sire is nearly thorough-bred, dogs of a superior description, but certainly not the best dogs, are sometimes produced by the Newfoundland or some other bitch not strictly a pointer. We are not willing to allow that the pointer is improved in any quality that renders him valuable to the sportsman, by a cross with the hound or any other sort of dog; though we cannot deny that the setter is materially improved in appearance by a cross with the Newfoundland dog, but what it gains in appearance, it loses in other respects.

Breeding mongrels, especially crossing with hounds, has given the gamekeepers and dog-breakers an infinity of trouble which might have been avoided by keeping the blood pure. The best pointer is the offspring of a pointer-bitch by a pointer-dog; such a dog is nearly broken by nature. The Spanish pointer seldom requires the whip; the hound pointer has never enough of it. One of the main sources of the sportsman's pleasure is to see the dogs point well. A deal is said about this and that dog being remarkably fine-looking; the only time to appreciate the beauty of a dog is when he is ranging and pointing; then let the sportsman compare the real pointer with the spurious one.

Courage[1] is another attribute of the pointer; a high-couraged pointer will continue ranging till he has not, as the saying is, a leg to stand upon, even though he should not meet with game.

The usual price paid for breaking a dog is from two to five guineas. The breaker runs the dogs in spring, and again in August, but without the gun; this, followed by a week's shooting in September, renders their education complete, but unless they have sufficient practice afterwards, the initiatory lessons will soon be forgotten. Young dogs will learn more in six successive days, than in six weeks, if taken out only at the rate of one day per week. The dog-breaker should be a person of discriminating judgment, and possessed of a good temper; and the art of winning, not by brute force, but by judicious management, an ascendancy over the dogs entrusted to his care. Breaking dogs, when many young ones are taken out together, is a very difficult and tiresome task. One or more old staunch dogs are usually allowed to accompany the young ones, to induce them to back. A dog pointing is conscious of the presence of game. A dog which backs another is not aware of the proximity of game at the time, otherwise than by inference. Whenever the dog in advance points, it is the breaker's duty to make all the rest that acknowledge the scent to point, and all that do not acknowledge the scent should be shown the dog pointing, and be made to back, which is done by the breaker holding up his hand, and crying, in an undertone, "to-ho." The dogs are taught to fall the moment the game rises, or on the report of a gun. They should come in on hearing their names or the whistle, and should never be allowed to pass a fence before their master. The efficiency of the training which a dog has received may be conjectured from his manner of quartering his ground. He should range at a short distance in advance of the shooter, alternately to the right and left; and this should be taught rather by the motion of the hand, or by the person turning at the same time, than by the voice. An offence should never be overlooked if the dog seems conscious of it; but the breaker's knowledge of the disposition of the dog should be his guide in regulating the punishment. Some dogs will not bear the whip, or even rating, but require encouragement and good words on all occasions. When it is necessary to flog a headstrong dog, it should be done severely, the blows falling on the side, from the shoulder to the flank. The lash or switch with which the dog is punished, should not be made to lap round the body, nor should the dog be kicked. When the dog is in fault, and is very eager in pursuing the sport, no punishment that will be longer remembered can be administered than making him crouch five or ten minutes. In common with other sports, shooting has a vocabulary of its own. We have elsewhere given a list of some of the words made use of by the breakers and sportsmen to the dogs, which we transcribe, many of them being anything but euphonious to the unaccustomed ear. "*To-ho* spoken in an under-tone, when the dog catches the first notice of the scent of game, is a warning to him that he is close upon game, and is a direction to him to stand. There is no necessity for using it to a dog that knows his business. Spoken in a peremptory manner, it is used to make the dog crouch when he has flushed game, or been otherwise in fault. *Down-charge*, or *down-to-charge*, is used to make the dog, whether it be near or at a distance, to crouch when the shooter charges, that the dog may not flush game when the shooter is unprepared. When the dog will not crouch, but continues beating, the leg-strap may be put on. *Take-heed*, and *be-careful*, are used when the dog ranges over ground where it is customary to find birds. *Take-heed*, is a word of correction: *be-careful*, of encouragement. The former is used by way of caution or notice to prevent the dog flushing birds by running over the ground too fast; the latter is likewise a caution, but used when the dog beats slowly or carelessly. *'Ware fence* is used to prevent dogs passing a fence before the gun. The dog should never, on any account, leave an enclosure until its master has left it. *'Ware*, or *beware*, is used to rate a dog for giving chase to a hare, birds, or cattle. *Seek*, is a direction to the dog to look for a dead or wounded bird, hare, or rabbit. *Dead* is used to make a dog relinquish his hold of dead or wounded game. The retriever drops it. The dog should retain possession of wounded game until it is taken from him; for should he suffer a bird that is only slightly wounded to disengage itself from his grasp, another *seek* becomes necessary, and the bird is either lost, or despoiled of its plumage by the catching and recatching. Some dogs are taught to bring the game to their master. The breaker should teach the dog, in all cases, to retain game until it is taken from him, or until he hear the word *dead*, when he should instantly drop it. The dog should be punished if he break the skin with his teeth."[2]

The most useful dogs are those which are best broken. As much depends on the breaking as the breed of a dog. Dogs should be constantly shot over during the season by a successful shot, and exercised during the shooting recess by some person who understands well the management of them, otherwise they will fall off in value. The half-bred ones will become unmanageable, and even the thorough-bred ones will acquire disorderly habits.

We look upon the setter to be an inferior kind of pointer, perhaps originally a cross between the pointer and the spaniel, or some such dog as the Newfoundland, for it has some qualities in common with each. The pointer has the finer nose, and is more staunch than the setter. Pointers are averse to water; setters delight in it; hence the advantage of the latter on marshes to the snipe shooter. No pointer should be made to hunt alone; that is the duty of a retriever. The setter will face briars and gorse bushes better than the pointer, which is in this respect a tender dog; and for this reason the setter is preferred to the pointer for cover shooting. Besides, his being not so staunch as the pointer, is an additional advantage in heavy covers. The sportsman who shoots over well-broken pointers, frequently passes game in the woods, while the pointers, which are not seen by him, are at their point; the setter, being more impatient to run in, affords the shooter many shots in cover, which the over-staunch pointer would not. The pointer is always to be preferred on open grounds. In hot weather the pointer will endure more fatigue than the setter.

The Spaniel.

The Spaniel or Cock Dog. The spaniel is the best dog for beating covers, provided he can be kept near the gun. He is generally expected to give tongue when game is flushed; some spaniels will give notice of game before it springs, which may be very well where wood-cocks only are expected to be found. Wood-cock and pheasant shooting are usually combined; where covers are limited, pheasant shooting cannot be conducted too quietly. Wherever the underwood is so thick that the shooter cannot keep his eye on the dogs, spaniels are to be preferred to pointers or setters, whatever species of game the shooter may be in pursuit of. If spaniels cannot be kept near the shooter, they are the worst dogs he can employ.

Retrievers.

Retrievers. The business of the retriever is to find lost birds. Newfoundland dogs are the best for this purpose. They should have a remarkably fine sense of smelling, or they will be of little use in tracing a wounded pheasant, or other game, through a thick cover, where many birds

[1] Courage, as applied to the pointer, signifies a willingness and determination to range; it is an union of the qualities known by the terms mettle and bottom, as applied to horses.

[2] The Oakleigh Shooting Code. London, Ridgways. Third edition.

Shooting. have been running about. A good retriever will follow the bird on whose track he is first put, as a blood-hound will that of a human being or deer. They should be taught to hunt and retrieve, or in many instances their finding a wounded bird would be of no advantage to the shooter.

We proceed next to give some description of the art of shooting game, in the course of which we shall endeavour to confine our obseravtions to such of the habits and peculiarities of the birds and quadrupeds under notice, as it is essential the shooter should be made acquainted with, and at the same time to detail the means of proceeding most likely to ensure success in the pursuit of them.

The Partridge. *The Partridge.* We commence with the partridge, as shooting that bird is generally the young shooter's first lesson at game, although in the order of the season grouse shooting takes precedence. Partridge shooting commences on the first of September, and ends on the first of February.

The habits of the partridge at different seasons should be closely understood and studied by the shooter, that he may be able, with a tolerable degree of certainty, to find them at any given time. In the early part of the season, they will be found, just before sunrise, running to a brook, a spring, or marsh, to drink; from which place they almost immediately fly to some field where they can find abundance of insects, or else to the nearest corn-field or stubble-field, where they will remain, according to the state of the weather, or other circumstances, until nine or ten o'clock, when they go to bask. The basking place is commonly on a sandy bank-side facing the sun, where the whole covey sits huddled together for several hours. About four or five o'clock, they return to the stubbles to feed, and about six or seven they go to their jucking-place, a place of rest for the night, which is mostly in aftermath, or in a rough pasture field, where they remain huddled together until morning. Such are their habits during the early part of the season; but their times of feeding and basking varies much with the length of the days. While the corn is standing, unless the weather be very fine or very wet, partridges will often remain in it all day; when fine, they bask on the outskirts; when wet, they run to some bare place in a sheltered situation, where they will be found crowded together as if basking, for they seldom remain long in corn or grass when it is wet. Birds lie best on a hot day. They are wildest on a damp or boisterous day.

The usual way of proceeding in search of partridges in September is, to try the stubbles first, and next the potato and turnip field. Birds frequently bask amongst potatoes or turnips, especially when those fields are contiguous to a stubble-field. The best partridge shooting is obtained in potato and turnip fields. It not unfrequently happens that potatoes or turnips are grown on a headland in a corn field; in that case the headland will be a favourite resort of birds.

After the middle of October it is ever uncertain where birds will be found; the stubbles having been pretty well gleaned, birds do not remain in them so long as in the early part of the season. When disturbed at this time they will sometimes take shelter in woods, when they are flushed one by one. The best shots that can be obtained at partridges in winter, are when the birds are driven into woods.

When a covey separates, the shooter will generally be able to kill many birds, but late in the season it is seldom that the covey can be broken. In November and December the shooter must not expect to have his birds pointed, but must remain content with firing at long distances. We transcribe the following observations on dispersing coveys: "In the early part of the season, when the shooter *breaks* a covey, he should proceed without loss of time in search of the dispersed birds, for the parent birds begin to call almost immediately on their alighting, the young ones answer, and in less than half an hour, if not prevented by the presence of the shooter and his dogs, the whole covey will be re-assembled, probably in security in some snug corner, where the shooter least thinks of looking for them. As the season advances birds are longer in re-assembling after being dispersed. It is necessary to beat very closely for dispersed birds, as they do not stir for some time after alighting, on which account dogs cannot wind them until nearly upon them, especially as they resort to the roughest places when dispersed. Birds dispersed afford the primest sport. The pointing is often beautiful, the bird being generally in a patch of rushes, or tuft of grass or fern, and close to the dog. When a bird has been running about some time, dogs easily come upon the scent of it; but when it has not stirred since alighting, and has perhaps crept into a drain, or run into a hedge-bottom, or the sedgy side of a ditch, no dog can wind it until close upon it, and the very best dogs will sometimes flush a single bird. In the month of October, and afterwards, the shooter will find it difficult to approach within gun-shot of a covey, nor can he disperse them, except by firing at them when he chances to come close upon them. Should he then be so fortunate as to disperse a covey, he may follow them leisurly, for they will then lie several hours in their lurking place, which is chosen with much tact, as a patch of rushes, a gorse bush, a holly bush, the bottom of a double bank fence, or a coppice or wood. The length of time that will transpire before a dispersed covey will re-assemble, depends, too, on the time of the day, and state of the weather. In hot weather, they will lie still for several hours. A covey dispersed early in the morning, or late at night, will soon re-assemble. A covey dispersed between the hours of ten and two, will be some time in re-assembling. A covey found in the morning in a stubble field, and dispersed, will next assemble near the basking place. A covey dispersed after two o'clock, will next assemble in the stubble field at feeding time. A covey disturbed and dispersed late in the afternoon, or evening, will next re-assemble near the jucking-place. A covey being disturbed on or near to their jucking-place, will seek a fresh one, perhaps about two fields distant; and if often disturbed at night on their jucking-place, they will seek another stubble field to feed in, and change their quarters altogether. The most certain method of driving partridges from a farm, is to disturb them night after night at their jucking-place, which is usually in a meadow, adjoining to a corn field, where the aftermath is suffered to grow, or in a field rough with rushes, fern, thistles, or heather. When a covey is dispersed on a dry hot day, it is necessary to search much longer, and beat closer, for the dispersed birds, than when the day is cool, and the ground moist. A dog should be only slightly rated for flushing a bird on a hot day."[1]

The number of birds in a covey varies much, perhaps the average may be from ten to fifteen. In some years, when the coveys are large after a fine hatching season, it is not uncommon to see upwards of twenty birds in a covey; and sometimes after a wet season, ten birds may be deemed a fair covey. Birds are always most numerous after a dry summer. When there are thunder-storms about midsummer, great numbers of young birds are drowned. The young birds have many enemies besides the elements, such as cats, young dogs, hawks, foxes, and vermin of different descriptions. When the eggs are taken, or the young birds destroyed soon after leaving the shell, there will be a second hatch. Sportsmen often meet with second hatches in September, when the old birds rise screaming, and generally alight within fifty yards, as if to decoy the dog or sportsman from the brood. In that case the fair sportsman will not fire at the old birds, but will call in his dogs and leave

[1] The Oakleigh Shooting Code.

Shooting. the ground. At such times he should look well after the young dogs, as, when they see the birds running, they are apt to snap up such of them as cannot get out of the way. The very young birds are called cheepers, from their uttering a scream as they rise. Full grown birds never scream as they rise, except when the young ones are helpless, nor do young birds after they are large enough for the table.

The cock partridge is distinguished from the hen by the brown feathers which form a crescent, or horse-shoe, as it is sometimes called, on the breast.

The pointer is decidedly the best dog for partridge shooting. Markers and retrievers will be of much service to the shooter whose object is to kill a great quantity of birds, rather than to enjoy the sport.

The Pheasant.

The Pheasant. The pheasant is the most splendidly arrayed of undomesticated British birds. It is deservedly in high request amongst sportsmen, and it claims the first attention of the game-preserver. The numberless plantations and coppices which are everywhere springing up, afford yearly additional shelter. The pheasant prefers woods of oak and beech, that it may feed on the acorns and mast. The fine old woods consisting of these trees may perhaps be diminishing, but they are more than replaced by plantations of larch or other quick-growing trees. Pheasants generally choose the larch or spruce-fir to roost in, and plantations of this description, if near corn, turnip, or potato fields, afford sufficient cover for them. They are, in many counties, allowed to become so numerous, as to do serious mischief to the labours of husbandry.

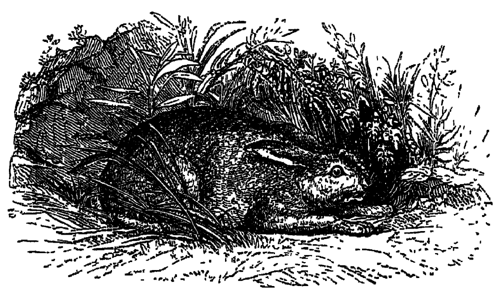
During August and the early part of September, pheasants will remain nearly all day in potato and corn fields. Pheasant shooting commences on the first of October, and ends on the first of February. In October, the shooter usually meets with them in potato and turnip fields, deep stubbles and rushy fields near covers, but especially under hedges, holly trees, or in coppices near to covers. In such situations they will suffer the shooter to approach very near to them; they are generally pointed by the dogs, and, a large majority of them being young birds, are easily killed; but in that month the trees are so full of foliage, and the briars and brushwood are so annoying, that it is seldom possible to beat the woods with any degree of pleasure, for not only are they almost impervious, but the pheasants are seldom seen when they rise, or if seen and shot, are very frequently lost, or not found without considerable loss of time. It is in November, when the birds have moulted, and when the leaves have fallen, and the brambles are decaying, and the paths in the woods are beginning to be worn, that pheasant shooting is in perfection. The birds are then full grown, and also better fed than later in the season.

It is not usual to kill the hens wherever pheasants are strictly preserved; but it is necessary to kill the cocks where they are too numerous. Pheasants do not pair, and as it is better that there should be but few cocks, the shooter's being able to single them out and kill them, tends ultimately to the increase, and not to the diminution of the number of birds in cover. At the commencement of the season the shooter will frequently flush a nide of pheasants, but in the after part of the season he will oftener find solitary birds. Pheasants will occasionally wander a considerable distance from the wood to which they belong, especially during winter, in search of food, and in wet and foggy weather. The pheasant basks at the root of a tree, or under a hedge, in the same manner as the partridge, but each bird nestles itself separately. Pheasants approach nearer to domesticated poultry than any other kind of game. Pheasant shooting is most destructive where the plantations are not more than forty yards wide; when the shooters remain on the outside, while the beaters and dogs rouse the game within. The pheasant shooter does not expect set shots; his object is to cause the birds to rise as near to him as he can. Having no notice of them, he should ever be on the alert for snap shots. Shooting.

A short double-barrelled fowling-piece, of wide bore, is preferable to a long one. The shot should be large, and it is well to use plenty of it. A close-shooting gun is not to be recommended to the pheasant shooter. The birds should rarely be fired at in cover when more than thirty yards from the gun, or they will escape wounded in the underwood. They are generally brought down within twenty yards from the gun. Pheasants are most plentiful in Norfolk, Suffolk, and some of the adjoining counties. There are some in every county in England, and in most of the counties in Scotland. A perfect bird has a white annular space on the neck, but this mark is often wanting.

The pheasant makes a considerable noise when rising, sufficiently so to unnerve the young and over-anxious shooter. The bird should be allowed to rise clear of the bushes, and to its full height, before the shooter fires at it, or it is probable he will fire too low; and again, the short fan-like feathers on either side of the tail appear, as the bird is rising, to be part of the bird, making the body seem longer and larger than it really is; and this circumstance, together with the rapidity of the movement of the bird when rising, is the cause of the shooter firing too low. The aim should always be at the head, unless the bird is crossing, and then well forward. Firing too soon, lest the bird should be out of reach, is a very common error, particularly with young sportsmen.

For reasons which we have before adverted to, the setter, or cock-dog, is to be preferred to the pointer for pheasant shooting. Pheasants will sometimes lie very close, so that it is with great difficulty they can be made to rise; therefore dogs that will dash into the thicket are most useful. Beaters and retrievers are indispensable to the pheasant shooter.



The Hare. The shooter seldom beats purposely for hares. Birds are mainly the object of his pursuit. He chooses his ground, and regulates the charge of his fowling-piece with reference to the birds he expects to meet with. Hares are started casually, as it were, while he is in quest of birds. Leveret shooting often commences with grouse shooting, on the 12th of August, though it is not uncommon, nor is it considered unfair, to kill leverets during the summer months. Hares are not in season until September. The shooter should desist from killing them in February, but he is not prevented from killing them at any season, by any legislative enactment, if he have taken out a game certificate. It is the prescriptive law of the chase, held sacred by sportsmen, that prevents him. The Hare.

In September, hares lie close, in hedges, in woods, or in growing corn, and are somewhat difficult to be found. They are always exceedingly restless in wild windy weather, and they are then found, particularly after a storm, in pasture and stubble fields. Dogs will frequently point them. In November and December, they are often seen on their seats, or forms, as they are sometimes called, by the shooter keeping his eyes on the ground about eight or ten

yards from him. It is usual, however, to allow the hare a chance of escape, by starting her before firing at her; it is accounted unsportsmanlike to kill puss on her seat. In January, hares are found on fallows, marshes, or in pastures, or in or near to gardens.

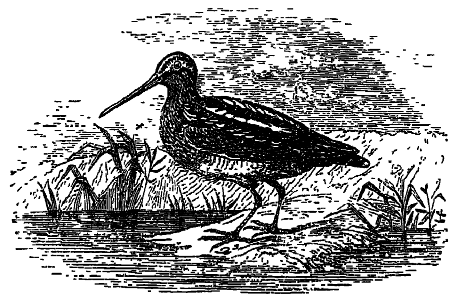
The shooter should fire well forward at a hare, and not too high. He should not fire at a long distance, as the probability of his wounding her would be greater than that of killing her. If running direct from him, a hare should not be fired at, unless within twenty-five paces from the gun, or she will often run off, though severely wounded in the hind-quarters. A beater will render essential service to the shooter in quest of hares, in the early part of the season; the beater walks on the contrary side of the hedge to the shooter, and a few yards in advance, so that the hare, to avoid the former, jumps out on the side of the latter. When beating hedges in the vicinity of covers, the shooter should take care to place himself on that side nearest the covers. When shooting at the edge of a cover, if the hare fired at is not quite deprived of the use of her legs, it would be advisable to fire again immediately, for should she crawl through the hedge, the chances would be against her being retrieved.

The Rabbit.

The Rabbit. Rabbits are alternately deemed game and vermin. They are sometimes shot for sport, sometimes for profit, and sometimes on account of the mischief they do to trees and other vegetation. They sometimes seat themselves all day long, after the manner of hares, but more frequently they remain the greater portion of the day in their burrows. As they are shy of approach, and run under ground on the least alarm, the shooter frequently finds it expedient to hide himself at a little distance from the warren, and wait until they come out. Where rabbits are numerous, as in most warrens they are, some will be continually playing within a few yards of the entrance of the burrows, and when found in such situations (for they are very tenacious of life), they should be struck very hard, or they will contrive to crawl, or rather roll into their earths, before the shooter can pick them up. It is astonishing what efforts they will make to escape, though three legs be broken, when near to the entrance of a burrow. It is of little use firing at them when they are more than twenty paces distant from the gun. Rabbits afford more what are termed snap-shots than any other game, as they are mostly found in or near to plantations, or amongst brambles, hollies, gorse or deep fern, in places of extreme difficulty. It requires a quick eye and steady hand to stop a rabbit running across furrows, or over uneven ground. Rabbits for sale, or when destroyed as vermin, are oftener taken by means of ferrets and nets, than killed by the gun. A short gun, having a large bore, and charged heavily with powder, and a small quantity of No. 4 shot, is best for rabbit shooting. It would be well that a companion or servant should lead a dog in a slip—a terrier is as good as any—to be loosed the moment the gun is fired; thus many a rabbit will be secured, that would else have run into its hole. When earthed, it frequently happens that a rabbit is not able to crawl more than three or four feet deep from the surface, where it dies, when it may be recovered by thrusting a bramble down the hole, and twisting it so as to entangle the rabbit; but a more certain method, if the rabbit is not too far down, is to screw the worm of the ramrod into its body, and so drag it out, as a cartridge is drawn from the barrel of a gun The best time for rabbit shooting is in the evening, or during sunshine just after a shower, when great numbers of the rabbits venture from their burrows.

The Bustard.

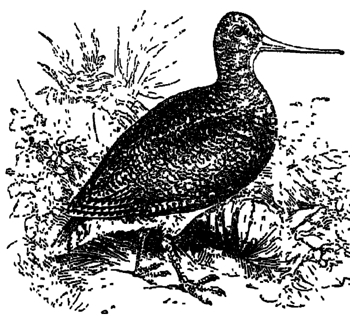
The Bustard. The bustard is a rare but valuable acquisition to the game-bag. As it cannot be approached unless the shooter takes advantage of some adventitious circumstances, it is seldom an object of pursuit to the sportsman. Bustard shooting commences on the first of September, and ends on the first of March.



The Snipe

The Snipe. There are three kinds of snipes, viz. the solitary or double snipe, the full or whole snipe, and the jack or half snipe. The last is considered to be scarcely worth powder and shot; it is the full snipe which principally engages the shooter's attention. We have before given directions for shooting this bird. "The common or full snipe is a shy bird when in company, but when alone will allow the shooter to approach within a dozen paces of it before it springs. When it does spring, however, it moves with a velocity that defies the epithet *slow!* It is best to shoot as soon as possible. The shooter will bring down a snipe with much less difficulty at from fifteen to twenty paces than at any other distance. The aim is thus taken before the bird begins to make its cross flights, and before it has attained its full speed. The irregularity of its flight is of little consequence during the first and second twirling, before the bird is safely on the wing, since its flight is then comparatively tardy. But let the snipe fly ten yards from whence it sprang,—let it be, for instance, twenty-five paces distant from the gun, it is then at the top of its speed, and in the very midst of its sidelong, elliptical gyrations, and more than a match for the majority of shooters, especially if the day be windy. A snipe killed at fifteen or twenty paces distance, with No. 7 shot, the aim being true, will be struck by twenty or thirty pellets, but the chances are more than twenty to one against the aim being true. The snipe, when struck, is generally three or four inches from the centre of the cone which the shot forms as it flies, which is very different from being in the exact centre. A section of the body of a snipe does not present a surface as large as that of a penny-piece. If any person will fire at a target at fifteen yards distance, he will find that a snipe would not be cut to pieces even at that distance, unless it chanced to be precisely in the centre of the charge as thrown. When speaking of a snipe presenting no larger a surface as a mark than a penny-piece, we of course mean a snipe flying directly from the shooter. It would be imprudent to shoot at a snipe flying across at less than twenty-five paces distance, as it then presents more than double the surface of one going straight from the shooter. Thirty paces is the distance we should prefer for a cross or oblique shot. At thirty, or even at twenty-five yards, unless the barrel throws shot remarkably close, there are interstices in the charge as thrown, in which a snipe would escape untouched. Provided the flight of a snipe were equally steady at all distances, and that in every instance the shooter could choose

Shooting. his own distance, a snipe would have the least chance for its life at twenty yards. But there are two points to be attended to in determining the proper distance—the flight of the bird, and the manner in which the shot is thrown. In snipe-shooting the latter is subservient to the former. The few full snipes occasionally found on heathery and rush-clad hills, as well as in the enclosed grounds, lie much more dispersed than the gregarious birds of the marsh. Hence those found on the uplands are easy, and those on the fens difficult of approach. It is, however, the same description of bird that is found in both situations." When the shooter uses wire cartridges, which, by the bye, are not precisely calculated for snipe-shooting, it would be prudent to allow the bird to move to a considerable distance before firing. It is scarcely necessary to add, that the shot used for snipe-shooting should be very small. When several snipes rise together, they are styled a wisp.



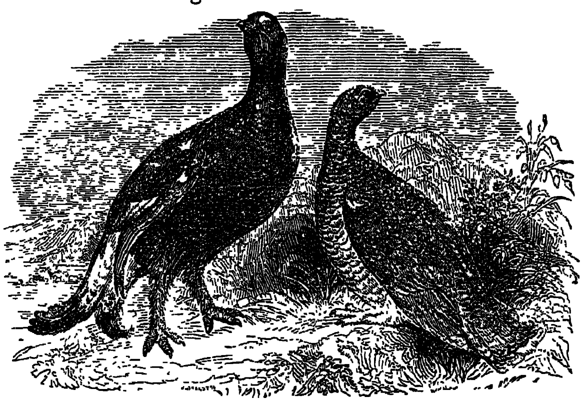
The Woodcock. *The Woodcock.* There is a proverb current among sportsmen, that to kill a woodcock is to perform a day's work, which doubtlessly originated in the circumstance of a woodcock being seldom found until a very large extent of wood has been closely beaten by both men and dogs. In the month of November, however, when woodcocks are most abundant, it would not be a difficult task, according to that standard of labour, to do the work of a week in a day, in any noted cover, for every cover frequented by woodcocks, (or cocks as they are called in the sportsman's nomenclature), acquires a notoriety which it seldom loses, since any wood well frequented with cocks one year, has generally a fair supply the next. But whether the same cocks that frequent a wood this year, return the next, with their offspring, or whether an entirely new set of occupants take possession, we leave the ornithologist to decide. A certain description of woods are seldom known to fail of woodcocks during the winter months; these woods or plantations are such as are swampy, or have a stream of water running through them, or woods abounding in springs, or where, from the nature of the ground, or want of draining, the top water encourages the growth of moss. The woodcock is rarely found where moss is not abundant. During a frost, cocks are found near fresh water springs; at other times, they are most commonly flushed in the open glades of the densest woods, or rather in those parts of the woods not choked up at the bottom with fern, rushes, or brambles, but where they can freely run about, and in those parts where willows, osiers, hazel-trees, or crate-wood is plentiful. In such places it will readily be ascertained whether there are cocks or not, by the borings in the moss or dead leaves, and by the droppings. Should the cock not be brought down, it will not fly far after being fired at; it should, when practicable, be marked down, as by this means several successive shots may be obtained at it when the gun is unsuccessful. It is seldom that the skilful shooter springs a cock which he does not eventually kill. The difficulty of woodcock shooting arises, for the most part, from the birds springing in the thickest part of woods, and contriving to wing their flight through the trees, in such a manner as to baffle the sportsman's aim. After being fired at in a wood, cocks will frequently alight amongst hedge-rows on the outskirts, especially under a hedge running close to and parallel with a water-course, when they are easily killed, as they will not rise until the shooter is close upon them; and their flight is not difficult to master when there are no trees to obstruct the aim. Woodcocks are found in October on moors, and in covers near the sea. About the last week in October they find their way to the inland covers, where they remain during the early part of the winter, and they are sometimes found there again in March. A sharp frost, or a dense fog, at the end of October or beginning of November, is usually the shooter's first intimation of the arrival of cocks; and if he is ambitious of the fame of killing them, he must fag hard during the month of November, or it is probable that his return for the season of the numbers bagged will not be satisfactory. November is unquestionably the best month for cock shooting. Shooting.

The Red Grouse. *The Red Grouse.* Grouse shooting commences on the 12th of August. We have already alluded to the vast extent of the northern moors. The number of birds killed on the opening day, on some parts, is very great. It is not uncommon for an experienced and skilful shooter, on the best moors, to bag fifty brace on the 12th of August. What may be termed a good day's sport, differs much on different moors. On well-preserved moors, the average may be from ten to twenty brace. On subscription moors, the shooter should not be dissatisfied if he has the opportunity of killing from three to five brace per day, during the first week of the season, though this would be deemed a low average for the Scottish moors. After the first week, few sportsmen, except those residing in the immediate neighbourhood of the hills, ever trouble the moor game.

Many causes contribute to the popularity of grouse shooting, amongst which may be enumerated the following. It commences during the parliamentary recess, and long vacation—the legislator's, lawyer's, and collegian's holiday; and it is no wonder that after being cooped up all summer, these, or any other classes of society, should seek relaxation in the sports of the field. August is the season when every one, from the peer to the shopkeeper, who can afford the indulgence, either rusticates or travels. In that month the casual tourist, the laker, and the angler, are often in the North, when the temptation to draw a trigger is irresistible. Grouse shooting fascinates the young shooter more than any other kind of sport, inasmuch as the season commences with it. The opening day is looked forward to with pleasing anticipation all summer. To the more practised sportsman, grouse shooting recommends itself by reason of the superiority of the sport over every other kind of shooting. Partridge shooting is a comparatively tame and uninteresting amusement. Partridge shooting, as compared with grouse shooting, may be termed domestic sporting. To the majority of sportsmen, a grouse shooting excursion only occurs once a year, and then lasts only a few days. The sport therefore seldom palls; but during the long interval of time that elapses between each, the coming season is ever looked forward to with additional interest. Grouse shooting is, in many respects, a source of greater expenditure to the sportsman: it requires more preparation, and is attended with more difficulties than any other kind of shooting; but these circumstances, whatever some people may imagine to the contrary, so far from detracting from, serve to enhance the enjoyment of the sport; for we are apt to estimate whatever is obtained with difficulty and expense at a higher rate than what is gratuitously afforded us. To the lover of the romantic and the picturesque, grouse shooting has attractions of the highest order. It is the sport of all others peculiarly British: the partridge, the pheasant, the black-cock, are widely dispersed over other countries; but the red grouse is only found in the British Islands.

Shooting.

There are seldom more than a dozen grouse in a brood; rarely indeed so many. Towards the end of autumn, the broods congregate together, and are seldom seen afterwards until pairing time in January or February, except in great numbers. Broods thus associated are termed packs. When it happens that the birds are well grown at the opening of the season, and much fired at in August, they will pack before September. When there is fine weather in August, grouse, until the broods are packed, will suffer the shooter to approach very near to them before they rise. In wet or windy weather they are wild. Very few grouse are killed by the sportsman after August; they are then scarcely approachable. Grouse delight in tall young heather, when there are plenty of bare places or pads or tracks. Hares also, and cocks, and we may perhaps add, pheasants, in their respective covers, delight in those parts where they can run about freely. The brow of a hill is more likely ground than either extreme heights or valleys, or flats. Solitary birds lie better than broods. When birds are wild, the shooter should follow an individual rather than a brood. It is well understood by sportsmen, that the fewer birds there are in a brood, nide, or covey, the better will they lie. Grouse bask on the sunny hill-side, oftentimes under a rock, or in a stone pit, during the middle of the day, at which time the task of ranging for them is toilsome in the extreme. Grouse shooters should be accompanied by a guide and markkers. The former is indispensable to a person not intimately acquainted with every turn and knoll, during the mist that nine mornings out of ten envelopes the hills in August. It is inconceivable how completely bewildered a person who fancies he is acquainted with every inch of ground may be when surrounded by the haze. Neither sun, moon, nor stars are visible; nor is there a fence, road, or building to direct him. A stone pit, or mountain rill, are often the only objects that present themselves, except the interminable heather. The distant hills that would else be his guides, are shut out from his view, which does not extend beyond the range of his fowling-piece. At such times it requires no ordinary precaution to prevent losing young dogs, which can scarcely be prevented running off when a gun is fired in the distance. During the continuance of the mist, which generally disappears about eight o'clock, markers can be of but little use, except that they may be employed in carrying a basket, extra guns and shot, or leading dogs, of which it is well to have a change. No dog can range two days successively for grouse. Pointers, for reasons we have before given, are preferable to setters, or any other kind of dogs, for grouse shooting. Grouse shooters should separate and range singly; they should have no noisy attendants; nor any dogs that require rating. The sport cannot be carried on too quietly. If the shooter throws off before eight o'clock, which it is not prudent to do unless there are many guns on the moors or foul weather is expected in the afternoon, he should run only one dog as long as the heather is wet, afterwards two, and in the afternoon three dogs. In wet weather one dog is quite sufficient. If hot weather, we advise rest from eleven to two. If the shooter have not exhausted himself during the middle of the day he will best fill his bag in the afternoon; he may not, indeed, then find so many, but those he does find will be dispersed birds that will almost lie to be trodden on. An old shooter thus on a dry afternoon following a wet morning will sometimes load himself or his attendant, after the less experienced have left the moor disgusted, with scarcely a bird in their possession. Shooters are generally recommended to carry as heavy a gun as they can conveniently manage on the moors. It should be borne in mind that the heaviest gun will do most execution; but none except those accustomed to such exercise, can carry a heavy gun with comfort all day long, exposed to an autumnal sun. We would therefore not recommend barrels more than thirty inches long, nor of a larger guage than sixteen, on account of the excessive heat of the weather at this season. As the sportsman, in grouse shooting, has ever an opportunity of choosing his own distance when birds rise near to him, he will be more certain of killing if he let the birds fly twenty-five yards from him before he fires the first barrel, when, if he have both barrels cocked, he will have ample time to throw in the reserve barrel while the birds are within reasonable distance. In nothing is the superiority of the detonating over the flint lock more apparent than in its allowing the shooter to fire the second so soon after the first barrel. We suspect that the habit of taking the gun from the shoulder after the first barrel was fired, originated in the necessity of waiting until the smoke from the pan was blown away, which nuisance no longer exists. A person who is a decidedly bad shot should not use the cartridge in the first barrel, as the loose charge gives a larger circle at a short distance, and consequently increases the chance of killing.



The Blackcock.

The Blackcock. Black game shooting commences on the 20th of August, and ends, with red grouse shooting, on the 10th of December. Black game frequent moors covered with heather, but they are as often found in rushy fields, or even in stubbles adjoining to moors. They are not met with at any great altitude, but confine themselves chiefly to the lower hills, or the base of the loftier mountains. They are seldom found, except where there are plantations or forests of fir trees. Black game do not frequent the central parts of large wastes so much as those parts bordering on inclosed lands. Red grouse recede where civilization progresses; and they are consequently in a fair way, at no very distant period, of being banished from England. As a vast extent of heath-land is not requisite for black game, there is no room to fear their extinction for some centuries to come. Although not so numerous as red grouse, they are more widely scattered over England. Even in the south of England there is cover congenial to them. Should both black and red game become extinct in England, the hills of Scotland will long afford shelter to each. With the exception of the pheasant, black game is the only species of game not yearly diminishing in number in Britain. A full-grown blackcock weighs the same as a fine pheasant cock, about three pounds and a half. The female, which is called the grey-hen, and ought never to be fired at, is much smaller. Black game shooting on moors resembles red grouse shooting, and in the woods, pheasant shooting. The black cock is a magnificent bird, and an old one is ever deemed a valuable addition to the contents of the game bag. Black game have increased very considerably in England during the last few years, still they are much more abundant in Scotland. Sweden is perhaps the country best suited to them.

The Capercailzie.

The Capercailzie. Similar to the blackcock, in many respects, is the capercailzie, or cock of the wood, once the native, and now the denizen of the Highland forests. The

Shooting. capercailzie cock weighs sixteen pounds. Speaking of this bird, as it exists in Sweden, Mr. Lloyd says,[1] "The favourite haunts of the capercali are extensive fir woods; in coppices or small cover he is seldom or never found. The principal food of the capercali, when in a state of nature, consists of the leaves of the Scotch fir; he very rarely, however, feeds upon those of the spruces; he also eats juniper berries, cranberries, blaeberries, and other berries common to the northern forests; and occasionally also, in the winter time, the buds of the birch, &c. The young capercali feed principally at first on ants, worms, insects, &c." It was the felling of the timber, aided, perhaps, by the cross-bow, which is not ill-adapted to the purpose, that exterminated this primeval habitant of the old Caledonian forests. Some years since an attempt was made to re-introduce this bird to its ancient haunts in Scotland, but without success. "It is a pity," continues Mr. Lloyd, "that attempts are not made once more to introduce the capercali into the United Kingdom, for, if the experiment was undertaken with judgment, it would most probably be attended with success; the climate, soil, &c. in Scotland, at least, not being very disimilar, in many respects, to the south of Sweden. In Scotland, besides, independently of the natural forests, there are now considerable tracks of land planted with pines, from which trees, when the ground is covered with snow, those birds obtain nearly the whole of their sustenance." Since this was written, several brace of these birds have been sent over from Sweden; and on the estates of the Marquis of Breadalbane the experiment of localising them is in course of trial. We believe they were procured by Mr. Lloyd himself, and under his auspices, from his knowledge of the habits of the bird, we doubt not that the cock of the wood will become permanently established in the Highlands. It may be inferred that the same description of country (the heaths and forests being on a more extended scale,) which suits the blackcock, would likewise suit the capercailzie, since, as Mr. Lloyd observers, "the capercali occasionally breed with the black game; the produce of which partake of the leading characteristics of both species. Their size and colour, however, greatly depend upon whether the connexion was between the capercali cock and the grey hen, or *vice versâ*." In winter, the male birds congregate in packs after the manner of black game. In Sweden the capercailzie is usually shot with the rifle.

The Ptarmigan. *The Ptarmigan.* We have now for some time traversed, with the reader, the highest hills that are covered with heather, but there are heights beyond. The poet says,

> For Liberty! go seek
> Earth's highest rocks and ocean's deepest caves!
> Go where the eagle and the sea-snake dwell![2]

It may be admissible in poetry to give the highest cliffs to the king of birds, but zoology assigns a lower elevation to "the eagle's birth-place;" yes, you may ascend above the ăerie of the eagle, where the croak of the raven is never heard, where the fox and the weazel but seldom disturb the lonely habitants. You may ascend until, in the glowing language of Mr. Mudie,[3] "you begin at last to feel alone, severed entirely from the world of society, of life, and of growth, and committed to the solitude of the ancient hills and immeasurable sky. The snow lies thick on the side of the summit, and even peers over the top, defying the utmost efforts of solstitial heat. There is no plant under your feet, save lichen on the rock, apparently as hard and as strong as that to which it adheres—it can hardly be said to grow—and moss in some crevice, undistinguishable from the dull and cold mud into which the storms of many winters have abraded the granite. You are above the reach of all sound from the inhabited parts of the country." And what do we find in this region of snow? "A few mottled pebbles, or at least what appear to be such, each about twice the size of your hand, lie at some distance, where the decomposed rock, and the rudiments of what may be called the most elevated mountain vegetation, just begin to ruffle the surface. By and by a cloud shadows the sun, the air blows chill as November, and a few drops fall, freezing or melting in their descent, you cannot well tell which. The mottled pebbles begin to move; you throw a stone at them to shew that you can move pebbles as well as the mountain. The stone hits beyond them; they run toward your feet, as if claiming your protection; they are birds, ptarmigan, the uppermost tenants of the island, whom not even winds, which could uproot forests, and frosts, which could all but congeal mercury, can drive from these their mountain haunts. It has often been observed, that of all the human inhabitants of the earth, the mountaineer, be his mountain ever so barren, is the last to quit; and the same holds true of the mountain bird." The same writer traces the different elevations at which various species of game is found, beginning with the pheasant, as the tenant of the lowermost woods; the partridge, of the plain; the blackcock, of the confines of cultivation; the grouse, of the lesser hills and mountain-side; and the ptarmigan, of the snow-crowned summits. He also adds, "in these birds we trace a sort of resemblance to the general colour of the places which they inhabit, though we know not well the cause of the colour in either case. The ptarmigan is mossy rock in summer, hoar frost in autumn, and snow in winter. Grouse are brown heather, black game are peat-bank and shingle, and partridges are clods and withered stalks all the year round." And we will add, the capercailzie is the black branch of the pine. A similar scale is applicable to the seasons at which these birds are hatched. Although, taking each species individually, we find the earliest birds in the warmest country and on the richest land: collectively, the order is reversed; the higher their location, the earlier do they arrive at their full growth. The ptarmigan is ready for the table before the period at which it may be legally shot, the twelfth of August. Descending the hill, we find the red grouse not three parts grown at that period. A little lower, and the scarcely-fledged black-cock rises almost helpless, on the twentieth of August. Lower still, on the fertile plain, the young partridge does not assume his grey mantle and purple crescent until long after the first of September. And in the warm woods the pheasant does not don his panoply of gold until the fall of the leaf.

Few are the sportsmen who climb the granite cliffs, and wade the winter snows in which ptarmigan delight to bury themselves. A ramble there, is a journey of curiosity or observation, rather than a sporting excursion. It is a pilgrimage to the loftiest Highland altitudes. The fowling-piece becomes converted into the palmer's staff; and the sportsman merges in the adventurer, the enthusiast, the worshipper of Nature! (O. S. C.)

SHORE, JANE. See ENGLAND, § *Edward IV.*

SHOREHAM, NEW, a parliamentary borough, market-town and seaport of England, in the county of Sussex, at the mouth of the Adur, 6 miles W. of Brighton, and 56 S. by W. of London. It consists for the most part of irregular streets and quaint old houses, but has recently been much improved. Near its centre stands the market-house, supported on Doric pillars. The parish church is a fine specimen of Norman architecture, being the remains of a large cruciform edifice: the nave is in ruins, but the east front and tower are very fine. The town contains also places of worship for Independents and Wesleyan Methodists. Here, too, is a grammar school, called the College of St Nicholas; as well as various other schools, a museum, conservatory, and theatre. The custom-house is an elegant building in the Grecian style. The harbour is formed by the Adur, which has a bar at its mouth, having from 14 to 17 feet of water at high tides. An artificial channel has been cut for the river, with piers on each side. The chief business carried on in the town is ship-building. Many people are also employed in fishing, and there are extensive manufactures of cement. The Adur was formerly crossed by a ford, but a handsome suspension bridge was erected at Shoreham in 1833. The number of sailing vessels registered at the port, December 31, 1857, was 129, tonnage 16,131; of steamers, 2, tonnage 31. In the year ending at that date, there entered 812 sailing vessels, tonnage 80,449; and 52 steamers, tonnage 8440—in all, 864 vessels, tonnage 88,889: and there cleared 374 sailing vessels, tonnage 17,901; and 52 steamers, tonnage 8154—in all, 426 vessels, tonnage 26,055. The borough of Shoreham returns two members to Parliament. It includes nearly all the rape of Bamber; and had, in 1851, a population of 30,553. That of the parish was only 2590.

SHORT, JAMES, an optician of note, was born in Edinburgh on the 22d of June, in the year 1710. After spending two years at Heriot's Hospital, he, at the age of twelve, was removed to the High School, where he showed a considerable taste for classical literature. In 1726 he entered the university, and took his master's degree with distinction. He had been fortunate enough to have the celebrated Maclaurin for his preceptor, who having soon discovered the bent of his genius, and made a proper estimate of the extent of his capacity, encouraged him to prosecute those studies in which nature had qualified him to make the greatest figure. Under the eye of that eminent master, he began in 1732 to construct Gregorian telescopes, in which he attained to great perfection. In the year 1736 Short was called to London, at the desire of Queen Caroline, to give instructions in mathematics to the Duke of Cumberland; and immediately on his appointment to that honourable office he was elected a fellow of the Royal Society, and patronised by the Earls of Morton and Macclesfield. He made numerous telescopes, during his residence in London, of great magnifying power. He died on the 15th of June 1768, at Newington Butts, near London, in his fifty-eighth year.

SHORT-HAND. See STENOGRAPHY.

SHOVEL, SIR CLOUDESLY, a distinguished British admiral, was born of poor parents in 1650. He was first put apprentice to a shoemaker, but disliking this profession, he a few years afterwards abandoned it and went to sea. He was at first a cabin boy with Sir Christopher Mynns; but having applied to the study of navigation with indefatigable industry, his skill as a seaman soon raised him above that station. The corsairs of Tripoli having committed great outrages on the English in the Mediterranean, Sir John Narborough was sent in 1674 to reduce them to order. As he had received orders to try the effects of negotiation before he proceeded to hostilities, he sent Shovel, at that time a lieutenant in his fleet, to demand satisfaction. The Dey treated him with a great deal of disrespect, and sent him back without an answer. Sir John despatched him a second time, with orders to remark particularly the situation of things on shore. The behaviour of the Dey was worse than ever, and upon Shovel's return he informed Sir John that it would perhaps be possible, notwithstanding their fortifications, to burn all the ships in the harbour. The boats were accordingly manned, and the command of them given to Lieutenant Shovel, who seized the guard-ship, and burned four others, without losing a man. This action so terrified the Tripolins that they sued for peace. Sir John Narborough gave so favourable an account of this exploit, that Shovel was soon afterwards made captain of the Sapphire, a fifth-rate ship. In the battle of Bantry Bay, after the Revolution, he commanded the Edgar, and, for his gallant behaviour in that action, was soon afterwards knighted by King William. Next year he was employed in transporting an army into Ireland, a service which he performed with so much diligence and dexterity, that the king raised him to the rank of rear-admiral of the blue, and delivered his commission with his own hands. Soon afterwards he was made rear-admiral of the red, and shared the glory of the victory at La Hogue. In 1694 he bombarded Dunkirk. In 1703 he commanded the grand fleet in the Mediterranean, and did everything in his power to assist the Protestants who were in arms in the Cevennes. Soon after the battle of Malaga, he was presented by Prince George to Queen Anne, who received him graciously, and next year employed him as commander-in-chief. In 1705 he commanded the fleet, together with the Earl of Peterborough and Monmouth, which was sent into the Mediterranean; and it was owing to him chiefly that Barcelona was taken. After an unsuccessful attempt upon Toulon he sailed for Gibraltar, and from thence homewards with a part of the fleet. On the 22d of October, at night, his ship, with three others, was cast away on the rocks of Scilly, and all on board perished. His body was found on the island of Scilly by some fishermen, who stripped it of a valuable ring, and afterwards buried it. Some say he was murdered by the wreckers, but this statement cannot be verified. Paxton, the purser of the Arundel, hearing of his death, found out the fellows, and obliged them to discover where they had buried the body. He carried it on board his own ship to Portsmouth, whence it was conveyed to London, and there this eminent seaman was interred with great solemnity in Westminster Abbey. A monument was afterwards erected to his memory by the direction of the queen. Sir Cloudesly married the widow of his patron, Sir John Narborough, by whom he left two daughters.

SHREWSBURY, a market-town, parliamentary and municipal borough of England, capital of Shropshire, pleasantly situated on the Severn, 50 miles S. by E. of Liverpool, and 153 N.W. by W. of London. It occupies a commanding eminence which gradually rises from the banks of the river, whose stream gracefully bends in course round three sides of the town, thus forming a peninsula having its narrow isthmus towards the N.E. The general character of the town is antique; its streets are irregular, and many of its houses are picturesque old edifices, built, at least partially, of wood. The town, however, contains not a few very superior stone buildings. The river is crossed by two handsome bridges, the English and the Welsh, the former of which has seven arches, and the latter five. The English bridge leads to the suburb of Abbey-Foregate on the E., and the Welsh to that of Frankwell on the W. Portions of the ancient walls still remain, and also the keep of the castle, but the latter has been modernised. It is a square, solid tower of the age of Edward I. There is also a fine Norman gateway, and some remains of a very ancient British fortress. Many of the public buildings of Shrewsbury are remark-

able. Among them are the market-house, which was built in the reign of Elizabeth, and is one of the most richly decorated buildings of the kind in England; the town and county hall, a large commodious edifice; and a fine Grecian structure, containing the post-office, music hall, and newsroom. There are also numerous churches, some of which are possessed of much interest. The abbey church is so called because it formerly belonged to a Benedictine abbey, founded in 1083. It was originally cruciform, but was partially pulled down at the time of the dissolution of the abbey. The north porch, nave, and western tower are the portions that still remain. St Chad's is a handsome modern building of a circular form, in the Grecian style; St Alkmund's is also modern, with the exception of the tower and spire of the more ancient edifice, 184 feet high; and St Mary's is a spacious cruciform church in the Norman and early English styles. The last has very rich old stained windows, and an elegant tower and spire, rising to the height of 220 feet. Besides these, there are other places of worship, mostly modern, belonging to the Established Church, and to the Wesleyan, Primitive, and Calvinistic Methodists, Independents, Baptists, Quakers, Roman Catholics, and Unitarians. There are in all 13 churches and 26 dissenting chapels. The royal free grammar school occupies a lofty freestone structure, forming three sides of a court. This institution was founded by Edward VI., and greatly enlarged by Elizabeth. It has an endowment of about L.2600 a year, and many scholarships and exhibitions at the universities. In the present century this school rose to great celebrity under its master, Dr Butler, afterwards Bishop of Lichfield; and among its distinguished scholars in former times were Sir Philip Sidney and Fulke Greville. Shrewsbury has also a British school, and several national and charity schools. There are a public library, theatre, assembly rooms, circus, and public baths; a military depôt, town and county jail and house of correction, and a lunatic asylum. Near the entrance of the town, from London, stands a Doric column in honour of Lord Hill; and in the corn exchange, under the market-house, is a statue of the Duke of York, father of Edward IV., brought from the old Welsh bridge. To the S.W. of the town, along the river's side, is a place called the Quarry, supposed to occupy the site of a Roman theatre, and now used for a public walk. It has an area of 20 acres, and is planted with lime-trees. Various manufactures are carried on, especially those of thread, canvas, and malt; and the brawn and cakes of Shrewsbury have long been famous. There are also in the vicinity important iron-works. Salmon-fishing is pursued with much success in the Severn, and that river is navigable for vessels of thirty or forty tons. A large trade is carried on with the agriculturists in the neighbourhood, and railways to all parts of England radiate from the town. There are several private and joint-stock banks, and a savings' bank. Weekly and monthly markets are held. The borough is governed by a mayor, ten aldermen, and thirty councillors, and sends two members to the House of Commons. It is believed that a fortress was erected here by the Britons after they found the Roman Uriconium (Wroxeter) no longer tenable against the Saxons. This must have taken place in the fifth century. The fortress was called by the Britons *Pengwern*, or Alder Hill. But even this at length fell before the victorious arms of the Saxons, who changed the name to *Scrobbesbyrig*, or Shrubstown, whence the present name. In the time of Alfred, Shrewsbury was one of the chief cities in England; and his daughter Ethelfleda founded here the church of St Alkmund. After the Norman Conquest it formed part of the earldom of Shrewsbury, given by William to Roger de Montgomery, who built the castle here; but it was subsequently forfeited to the crown. Standing as it does on the confines of Wales, Shrewsbury was the scene of many conflicts between the rival nations. In 1215 it was taken by the Welsh under Llewellyn the Great, but not long retained; and, in 1264, it was again for a short time in the hands of the Welsh. Edward I., in 1277, strengthened Shrewsbury, and made it his head-quarters; and in 1283 assembled a Parliament here for the trial of David, the last prince of Wales, who was executed as a traitor. The name of Shrewsbury is likewise conspicuous in the Wars of the Roses, and in the historical dramas of Shakspeare. Here, in 1403, the forces of Henry IV. defeated the insurgents under the Percys and Owen Glendower. In the civil war of the seventeenth century, Shrewsbury was held by a royalist garrison until 1645, when it was surprised and taken by the parliamentary forces. After the Restoration, the castle and property attached to it were conferred by Charles II. on the Earl of Bradford, from whom they have been transferred to the Duke of Cleveland, the present proprietor. Pop. of the borough (1851) 19,681.

SHROPSHIRE, or SALOP, an inland county of England. It is bounded on the N. by Cheshire and the Welsh counties of Flint and Denbigh; on the W. by the Welsh counties of Denbigh, Montgomery, and Radnor; on the S. by Herefordshire and Worcestershire; and on the E. by Staffordshire. It is of an oblong figure, extending from N. to S., and contains a variety of projections and indentations. Its greatest length is about 48, and its greatest breadth 40 miles. Its superficial contents are 1343 square miles, or 859,520 statute acres.

The face of the county is very much diversified. On the western side it has the wild appearance of the adjoining principality of Wales. Several of the Welsh mountain-chains extend across the frontier of that country into Shropshire. Such are the Berwyn Hills in the north, which rise to the height of 1300 feet; the picturesque Breiddin Hills, on the right bank of the Severn; and a long range of smooth, rounded hills, extending from Radnorshire into Shropshire, and known under the name of Clun Forest. Throughout the rest of the county the land is rather undulating, tolerably wooded, and with many beautiful rivulets meandering along the different valleys. The whole tract of country in the east and north, from Wellington to the termination of the county between Oswestry and Chirk, exhibits the mild beauties of a fertile and cultivated district, enclosed by well-formed hedges into fields, of dimensions well calculated for advantageous husbandry, and ornamented with several seats of noblemen and gentlemen, which present a most pleasing succession of pictures to the traveller. In the portion south and west of the Severn, there are three principal chains of hills, extending from S.W. to N.E. These are on the west the Longmynd, in the centre the Caradoc Hills, and on the east Wenlock Edge. The last of these rises abruptly out of the valley on the west, but has a very gradual slope towards the east. The Caradoc Hills extend across the Severn, and terminate in the well-known hill called the Wrekin.

That singular insulated mountain, rising from a plain to the height of 1320 feet, exhibits its sugar-loaf form over the tops of the smaller elevations in its vicinity, and increases the interest of the scenery. In the southern division of the county, the Brown Clee Hill and the Titterson Clee Hill rise to greater elevations than the Wrekin, and produce much picturesque variety. These two are the highest summits in the county; the former reaching the height of 1805, and the latter that of 1750 feet.

The chief river is the Severn, which runs through the whole extent of the county from N.W. to S.E. It is navigable at all seasons to the Bristol Channel downwards, and in wet seasons upwards to Welshpool, in Montgomeryshire. Its whole course through Shropshire is 90 miles, flowing at first towards the east, and then turning to the

south. The fish found in the Severn, in its course through Shropshire, are salmon, pike, flounders, grayling, and eels. There are also some lampreys, but they are less abundant than in the lower parts of the river. The principal tributary rivers are the Camlet, the Vyrnwey, the Tern, the Clun, the Ony, the Teme, the Perry, the Rea, and the Corve. There are, besides, innumerable rivulets and streams, which adorn and fertilize the country. The lakes of Shropshire, though neither numerous nor extensive, form a variety in its landscapes rarely to be seen in the midland counties of England. Adjoining the town of Ellesmere is a beautiful lake of 116 acres, with some others smaller near it. On the western side of the county is Mereton Pool, of 45 acres. On the north of the Severn are Fennymere, Llynclyspool, and Ancot; and at Shrawardine is a fine lake of 40 acres. That side of the county which most abounds in running streams has few or no lakes. The canals of this county, if not equal in extent to those in some others, yield to none in the skill of their construction, in the obstacles they have surmounted, or in the beneficial consequences by which they have been followed. The first canal was a private undertaking by a Mr Reynolds, completed in the year 1788, for the conveyance of his ironstone and coals. It was of no great length, but a descent of 73 feet was conducted by a well-contrived inclined plane and double railroad, by means of which the loaded boat passing down drew up another with a load nearly equal to one third of its own weight. This contrivance was found to be applicable to similar purposes upon a larger scale, and was speedily adopted by a company who, under the power of an act of Parliament, constructed the Shropshire Canal, which passes through the most considerable iron and coal works, till it reaches the Severn. The Ellesmere Canal is a most important undertaking, as by it a communication is opened between the Severn and all the great canals and rivers in the north of England. Bristol and Liverpool are thus become connected by inland navigation; and the rivers Severn, Dee, Mersey, Trent, and Humber, are united for the purposes of conveyance. In other means of communication Shropshire is not deficient. It is traversed by many good roads; that from London to Holyhead, formerly the great route to Dublin, passing through this county. Several railways also afford more rapid means of transit. The Birmingham, Shrewsbury, and Chester line enters Shropshire from the east, and leaves it on the N.W. A branch of this line diverges to Stafford, and another shorter one to Oswestry. A great part of the Shrewsbury and Hereford line also lies in the county, running southwards from Shrewsbury to Ludlow. Besides these main lines, there are many short railways and tram-roads used in connection with the various mines for conveying their produce to the furnace or to the canals. The river Severn nearly forms a line of demarcation between two distinct geological formations which occupy the county; the northern portion, consisting for the most part of red sandstone, and the southern of older formations. The new red sandstone forms a basin round a central deposit of lias, between Whitchurch and Market-Drayton. Around and beneath this, occupying the whole north of Shropshire, and portions also of Staffordshire and Cheshire, lie the deposits of new red sandstone, with the lowest strata nearest the outside. The southern limit of this formation extends south of the Severn in the west of the county, and again at a point near the Caradoc Hills; but further east it does not reach so far as that river, and terminates near Newport on the border of Staffordshire. It is succeeded by various different formations. At some places Silurian rocks extend to the north of the Severn, and the Wrekin is composed of trap; but the most important deposits in this the central part of Shropshire are those of coal. Of these the most valuable is that of Coalbrookdale; but there are also extensive fields about Westbury and Pontesbury in the west; and others completely isolated near Oswestry in the north, and in several places in the south. A large extent of old red sandstone occupies the S.E. portion of Shropshire; and a separate deposit of the same rock forms Clun Forest in the S.W. The remainder of the county, a portion equal to one-fourth of its area, lying in the S.W., consists of the Silurian and Cambrian systems of rocks. Among these are limestone, sandstone, and several varieties of trap-rock.

In a county of such extent the soil must be very varied. On the eastern side, the valleys are flat and warm, and the soil generally of a sandy nature. In the middle part, the soil is most tenacious, and the bottoms of the wider valleys have frequently a stiff but rich clay. On the most western parts, the soil is very shallow, resting upon rocks of varied description; and is better calculated for sheep-pasture than for producing grain. There are some moorlands, but enclosures and drainage have considerably diminished their extent. A very great portion of the soil rests on a limestone subsoil; and almost the whole of the plains are easy to work with light ploughs and two or three horses. The easterly wind generally prevails in the spring, and the westerly in autumn; but the former is more remarkable for regularity than the latter. The whole of the county enjoys a salubrious air; but on the hills, on the western side, the cold of winter is most intensely felt.

The agriculture of the county has made considerable progress of late, though in some parts it is still in a very backward condition. In the west of the county progress is much retarded by the small size of the farms, and the short leases by which they are held. In this portion they frequently do not exceed 20 acres in extent, while in the east their size varies from 100 to 500 acres. Most of the farms are arable, but some depend chiefly on hay, dairy produce, and the rearing of cattle and sheep. The Herefordshire breed of cattle is common in the south, along with various mixed breeds. The most prevailing breed of sheep is one resembling the Southdown, but many of the New Leicesters are to be seen, and in the hilly parts of the county are many of the fine woolled Welsh sheep. The meadows on the banks of the Severn, and on the flat lands contiguous to the smallest streams, afford pasturage for numerous cows, whose milk affords a kind of cheese, commonly sold under the denomination of Cheshire, though much inferior to the genuine article. The corn generally cultivated is either wheat, barley, oats, or pease, and the crops on an average equal in productiveness those of the best districts of the kingdom. Hops are grown in small quantities upon that part of the county which adjoins to Herefordshire. Some small portions of land are appropriated to the growth of hemp and flax. The cultivation of potatoes has been very much extended of late years, and now furnishes a large proportion of the aliment of the labouring part of the population. The growth of hay, and the cultivation of artificial grasses, are more neglected than any other branch of rural economy. On the flat lands the deposits from the overflowing of the streams sufficiently enrich them without any artificial manure; but the hay produced on such situations is liable to be much injured by the floods that frequently occur in summer. This, however, is guarded against by embankments in the upper part of the river.

A great portion of the wealth of this county consists in the mineral productions, which are most profusely found beneath its surface. The chief of these are lead, iron, limestone, freestone, pipe-clay, and coals. The lead is procured in considerable quantities, chiefly from the mines of Stiperstone and Snailbeach. The matrix of the ore is crystallized quartz, sulphate and carbonate of barytes, and carbonate of lime. The quantity of lead ore obtained in the county in 1858 was 3994 tons, yielding 2993 tons of lead,

being considerably above the average of the previous ten years. The total amount of ore raised in that period was 35,602 tons, yielding 25,916 tons of lead, or 72·796 tons of metal for every 100 tons of ore. The iron ore is found contiguous to the coal, and frequently close to it. This is especially the case about Coalbrookdale, a division peculiarly rich in those minerals. This district is about 8 miles long and 2 broad, on the banks of the Severn, on the western side of the Wrekin, and running parallel with it, from N.E. to S.W. The whole, but especially the southern part, of the coal district, is considerably above the plain of Shropshire, so that at one part the height is 500 feet above the Severn. The works of the dale supply both iron and coal, as well as limestone, in great quantities; and every part of the process, from digging the ore to the completion of the manufacture, including the conversion of the coal into coke, is performed on the spot. Arthur Young, describing this part of the county, says—" Coalbrookdale is a winding glen, between two immense hills, which break into various forms, being all thickly covered, and forming most beautiful sheets of hanging woods. The noise of the forges, mills, furnaces, &c., with all their vast machinery, the flames bursting from the furnaces, with the burning coal, and the smoke of the limekilns, are altogether horribly sublime." A bridge of cast-iron, the first, we believe, constructed in this kingdom, thrown over the Severn, gives to the whole scenery a most romantic appearance. Soon after it was ascertained that iron might be made with coals reduced to the state of coke, as well as from wood, the operation of coking was begun here by Lord Dundonald, with a view to obtain the fossil tar in the course of the process. This operation led to the discovery of that gas, extracted from coal, whose brilliant light now serves to illuminate so many of our streets and public buildings. In this dale was discovered, in opening a coal-mine, a copious spring of fossil tar. It yielded, at first, very plenteously, but the quantity diminished in a few years, and although it still runs, its produce is but of small amount. Though the iron-works were first begun on a large scale in this dale, they are by no means confined to it; for in many other parts of the county they are carried on to an extent that is unequalled in any other country but Great Britain. The quantity of iron ore raised in Shropshire in 1858 was 150,500 tons, valued at L.38,135. There are in all 32 furnaces in the county, of which 25 are in blast; and these produced in the year above mentioned 101,016 tons of pig-iron. In the same year there were produced from 57 collieries, 749,360 tons of coal. The number of persons employed in the various mining operations in Shropshire, and in manufactures connected with them, amounts to several thousands. The manufacture of iron is here carried on with great care and skill, and with the aid of powerful machinery.

Besides the process of separating the iron from its ore, and bringing it into the state of bar-iron and pig-iron, the other steps in the application of that mineral to general purposes are made within this county. The larger kind of iron goods, whether cast or wrought, are prepared, and many of the iron bridges erected in different parts of the kingdom have been made here. Some of the largest establishments for making porcelain have been formed here, especially that for iron-stone china in Coalbrookdale. Glass, earthenware, bricks and tiles, are also made in the county, as well as coarse linen cloth, carpets, and gloves.

Shropshire contains two divisions, a north and a south; and is subdivided into 14 hundreds. It returns in all 12 members to Parliament; two each for the northern and southern divisions; and two each for the boroughs of Bridgnorth, Ludlow, Shrewsbury, and Wenlock. Its ecclesiastical division is into 225 parishes, with parts of 19 others; belonging to the dioceses of St Asaph, Hereford, and Lichfield. According to the census of 1851, the county contained in all 679 places of worship, with 145,186 sittings. Of the former, 291 belonged to the Established Church, 262 to Wesleyan Methodists of various subordinate sects, 59 to Independents, 31 to Baptists, 11 each to Calvinistic Methodists and Roman Catholics, 3 to Quakers, &c. At the same period the total number of public day-schools was 247, attended by 18,859 scholars; the number of private day-schools 312, attended by 6395 scholars. There were also 298 Sunday-schools, attended by 22,705 scholars, and 14 evening schools for adults, attended by 175 scholars.

Before the Roman conquest of Britain, the present county of Shropshire was divided by the Severn between the Cornavii on the east, and the Ordovices on the west. Under the Romans the same river formed the boundary between Flavia Cæsariensis and Britannia Secunda, the latter comprehending the modern Wales, and the former the centre of England. Numerous remains of old British camps still exist in various parts of the county, especially one called Caer Caradoc, near Church Stretton, and the Gaer ditches near Clun. The latter is believed by some to be the place where Caractacus was defeated by Ostorius Scapula. The chief Roman station was Uriconium, now Wroxeter, where there are extensive remains. There is also a camp near Bridgnorth, and a Roman road known by the name of Watling Street, traverses the county. After the departure of the Romans and the invasion of Britain by the Saxons, this county was the scene of frequent encounters between the natives and the invaders; and many of the half mythical exploits of the celebrated King Arthur are said to have taken place here. Ultimately the Saxons extended their dominion as far as the foot of the Welsh hills, and established in Shropshire and the adjacent county a kingdom called *Myrenaland*, or *Mercia*, the land of the marchmen or borderers. In order to defend this country from the attacks of the Welsh, Offa, one of its kings, erected a dyke extending from the Dee to the Bristol Channel. Several portions of this fortification may still be traced in the extreme west of Shropshire, and are still known under the name of Offa's dyke. At a later period the Danes also penetrated as far as this part of the country, and built a fortress on the Severn below Bridgnorth. When they were expelled, and the Heptarchy united under Alfred, Shropshire was made a county, deriving its original name of *Scrobbescyre* from *Scrobbesburg*, or Shrewsbury, its chief town. After the Norman conquest, almost the whole county was granted to Roger de Montgomery. Our limits do not admit of lengthened descriptions of the numerous remains of ancient architecture which are still existing in this county. The most remarkable are Haughmond Abbey, about 4 miles from Shrewsbury; the walls of Wroxeter, of British and Roman construction; the Abbey of Buildwas, founded in 1135 by Roger bishop of Chester, for monks of the Cistercian order; the Monastery of Wenlock, founded in 680, destroyed by the Danes, and afterwards re-established; the Roman camp, called the Walls, at Quatford; the castle of Ludlow, celebrated for its splendour in the reigns of Henry VIII. and of Elizabeth, during the latter period the residence of the Sidneys, and in the reign of Charles I. immortalized as the place where Milton composed some of his works; Wannington Castle, near Oswestry, a house of strength before the Norman conquest; Lilleshall Abbey, near Newport, with one of the most highly adorned Norman arches in the kingdom; and Boscobel House, with the oak in the grounds near it which served as a shelter to Charles II., when, after the battle of Worcester, he was closely pursued by the victorious party. The principal seats of noblemen and gentlemen are Walcot, belonging to Earl Powis; Lilleshall to the Duke of Sutherland; Hawkstone to Viscount Hill; Weston Hall

to the Earl of Bradford; Attingham House to Lord Berwick; Burwarton Hall to Viscount Boyne; Shavington Hall to the Earl of Kilmorey; Willey Park to Lord Forester; Acton Burnell to Sir Edward Smythe; Aldenham to Sir John Acton, &c. The population of Shropshire at each of the decennial periods of census was as follows:—in 1801, 182,695; 1811, 199,263; 1821, 215,058; 1831, 230,990; 1841, 241,685; 1851, 244,898.

SHROVE-TUESDAY is the Tuesday after Quinquagesima Sunday, or the day immediately preceding the first of Lent, being so called from the Saxon word to *shrive*, which signifies to confess. The reader may consult Brand's *Popular Antiquities* for an account of the ancient Shrovetide amusements of the people of England.

SHROUDS, a range of large ropes extending from the mast-heads to the right and left side of the ship, to support the masts, and enable them to carry sail. They receive their names according to the masts or portions of the ship to which they belong.

SHUMLA, or SHUMNA, a fortified town of European Turkey, Bulgaria, in the pashalic and 58 miles S.S.W. of Silistria, 225 miles N.N.W. of Constantinople. It is a place of great importance in a military view, insomuch that it has obtained the name of the key of the Balkan; for to this point there converge roads and tracks from all the chief fortresses on the Danube to the north, and from the passes of the Balkan to the south. The fortifications of the town are not themselves the sources of its strength, but the entrenched camps that have been formed on the heights to the south and west, commanding the town and preventing an enemy from approaching by this route to the passes of the mountains. The town has more the appearance of a vast village than of a fortified place; it is spread over a wide extent of ground, each house standing with its own stables and cow-houses in the middle of a separate yard. A rivulet divides it into an upper and a lower town. The former is inhabited by Turks, and contains numerous handsome mosques and baths; while the latter, occupied by Jews and Christians, is very unhealthy, chiefly on account of its extreme dirt. Shumla contains a Greek and an Armenian church, several Bulgarian schools, infantry and cavalry barracks, and a new hospital, all of stone. There are three forts in the plain and one on the hills; but the fortifications were in an unfinished state until the Russian war in 1854, when they were completed. Some remains of antiquity still exist here in the shape of decaying arches and fountains. The mausoleum of Djezzar Hassan Pasha is one of the finest objects in the town. The copper and lead foundries of Shumla are considered the best in Turkey; weaving and silk-spinning are also carried on, and the trade of the town is very considerable. Wine, hardware, and manufactured goods are the principal articles of commerce. Shumla was first conquered by the Turks in 1387. In subsequent times it has been three times attacked by Russian armies, but always without success. The dates of these attempts were 1774, 1810, and 1828. On the last occasion, however, in the following year, Marshal Diebitch, leaving the town on his right, succeeded in crossing the Balkan by a pass further to the east. The population of Shumla is estimated at 30,000.

SHUMSHABAD, a town of British India, in the district and 12 miles N.W. of Furruckabad, 88 miles N.E. of Agra. It stands in a marshy track 8 miles from the west bank of the Ganges, and formerly was a much more important town than it is at present, yielding an annual revenue of L.20,000. Pop. 6920.

SHUSHA, or SHUSHI, a town of Asiatic Russia, capital of a circle in the government of Shamaka, Transcaucasia, 70 miles S.E. of Ganjeh. It is fortified, and occupies a strong position on a mountain accessible only from one side. Silk and woollen cloth are manufactured here. Shusha was founded by Nadir Shah, and was at one time the capital of the khanat of Karabagh. Pop. 13,469.

SHUSTER, a town of Persia, in the province of Khuzistan, at the foot of a low range of hills on the Karun, which is here crossed by an ancient bridge about 300 yards long, 170 miles W. by S. of Ispahan. Immediately above the town the river divides into two branches, thus enclosing it on two sides; while a wet ditch or small canal connecting the two completes the circuit of the town. A steep rock rises abruptly from the river's edge, and on this is built a castle, a place of no great strength, as its walls are dilapidated, and it is commanded by higher ground in the vicinity. In the castle is the large substantial residence of the governor. The town occupies the slope of the hill towards the S.W. It is mostly built of stone, and has many handsome edifices; the streets, however, are generally very narrow. It is divided into twelve quarters, each governed by its separate chief, according to a sort of feudal system. Having been almost depopulated by the plague in 1832, Shuster does not contain more than 13,000 inhabitants, though the number of houses exceeds 10,000.

SHUTTLE. See WEAVING.

SIAK, a native state in the Island of Sumatra, on the coast of the Strait of Malacca, extending from the equator to about 3. N. Lat., and from the central mountains down to the sea. It is nearly square, about 160 miles each way, and is bounded by the river Kampar in the south, and the Assahan in the north. It derives its name from the river Siak, which traverses its central portion, and overflows the low flat regions which lie along the coast. The chief productions of the country are rice, cotton, various vegetables and fruits, honey, ivory, and bamboos. There are large numbers of cattle and game. There are numerous trading places along the coast, and several islands afford behind them shelter for ships. The whole coast, however, is very much infested with pirates. The state is governed by a sultan, who resides at Siak, the capital. At this place an active trade is carried on in the produce of the country with Singapore, Penang, &c.

SIAM, an independent kingdom of Eastern India, extending from about the 5th to the 21st degree of north latitude, and from the 98th to the 105th degree of east longitude. Its area is probably not less than 250,000 square miles. It is bounded on the N. by Laos; E. by Laos, Camboja, and the Gulf of Siam; S. by the Gulf of Siam and the Malay peninsula; and W. by the Bay of Bengal, the Tenasserim provinces, and the Birman empire.

Within these boundaries are included not only Siam Proper, but likewise the tributary Malayan states on the south, the conquered territory of Camboja and Korat on the east, and the tributary Laos states on the north and north-east. The Malayan tributary states are Patani, Tringanu, Kalantan, and Quedah. The dependence of these states, however, especially the last three, is little else than nominal; with regard to Patani it is more complete, on account of its population being to a large extent Siamese. Camboja is now nearly divided between Siam and Cochin-China. Of this once powerful kingdom only a small remnant, of about two degrees of longitude, and three or four of latitude, with the single seaport of Kampot, and perhaps half a million of subjects, remain to the present monarch. Korat is only a small territory; but it has a walled town of great strength, which can only be approached through a dense and dangerous jungle. The Laos states are divided into two very distinct sections; those who *tattoo* their bodies, and those who do not. The tattooed, or black-bellies, occupy the districts of Xieng-Mai, Laphun, Lakhon, Muang-Phrë, and Muang-Nan; the non-tattooed, or white-bellies, live in the districts of Muang-Lom and Muang-Luang-Phra-Bang. The western region of the country is inhabited by the white-bellies, the eastern by the black-

bellies. They are divided into a number of petty kingdoms; but few of them are strictly independent, most of them being tributary to the king of Siam. (See *Royal Geo. Soc. Jour.*, vol. xxvi.)

The country of Siam is traversed, from north to south, by several mountain-chains, which descend from the mountainous province of Yun-nan, in China. Two of these ranges enclose between them the fertile valley of the Menam, which may be said to comprise the whole of Siam Proper. The western chain separates the waters of the Menam from the Saluen, and extends southwards to the mouth of the Tenasserim river. On the eastern bank of that stream rises the chain of the "Three Hundred Peaks," a name derived from its sharp and conical summits. It terminates about 11. N. Lat.; but is succeeded by other ranges, which traverse the Malay peninsula. The mountain-chain which divides the Menam from the Mei-kong, or Camboja river, is little known; but where seen and visited it seems to be of moderate elevation, and is richly covered with vegetation. Of the western mountains of Siam, some of the summits are estimated to rise to the height of 5000 or 6000 feet; but as yet our information of the nature of the country is very vague and meagre. The mountains seem to be mostly covered with a thick jungle of trees.

Siam possesses a great extent of sea-coast. The Gulf of Siam is almost entirely bordered by its territory, and it has also about 500 miles of coast on the Bay of Bengal. Altogether, it may be said to have a coast-line of about 2000 miles. The Gulf of Siam is about 500 miles in length, from south-east to north-west, and has an average breadth of about 250. It is little exposed to the typhoons and tempests which do so much damage in the Chinese seas. There is a gulf-current, which, from October to March, flows from north to south, at the rate of nearly three miles an hour; after April its ordinary course is from south to north. "The Admiralty charts," says Sir John Bowring, "are full of extraordinary blunders. Some were pointed out by Mr Crawfurd more than a third of a century ago, but have remained uncorrected to the present hour." Recently, however, this gulf has been surveyed by Mr John Richards, R.N., and it is hoped that these errors will now be corrected. (See *Royal Geog. Society's Proceedings* for 1859.) The gulf contains numerous islands all along its coasts. They are of small size, but many of them are valuable as furnishing the edible birds' nests which form so large an article of commerce with China. In the Bay of Bengal, too, off the Siamese coast, there are numerous islands, usually of small size, rocky, and elevated. The largest are St Matthews and Salanga, or Junk Ceylon, each being about 16 miles in length by 6 in breadth. The channels between them are generally of great depth, and seldom less than 4 or 5 fathoms.

The practicability of establishing communication between the Bay of Bengal and the Gulf of Siam, by means of a ship-canal cut across the Isthmus of Krah, has been advocated by more than one writer. The direct distance across the isthmus, in about 11. N. Lat., is about 50 miles; and it is said that only a few miles of cutting would be required. There is on the one side the Pakchan river, which falls into the Bay of Bengal, and on the other the Choomphon river, which enters the Gulf of Siam, both navigable for boats; while the space between them is so low, that, according to the natives, the two rivers frequently commingle their waters during the spring-tides. A canal here would be of immense importance to vessels trading between India and Eastern Asia, and would effect a saving in time often to be estimated, not by days, but by weeks. "A ship-canal here," says Sir John Bowring "if practicable, would be next in importance to those which have been proposed to cross the Isthmus of Darien in America, and that of Suez in Egypt."

The most important river of Siam is the Menam, or Meinam, a name signifying, in Siamese, "Mother of Waters." It takes its rise in the mountains of Yun-nan, in China, by two branches, which unite about N. Lat. 22. The western, called Nan-ting-ho, rises about N. Lat. 24., and is the longer of these branches; but the Meiprein is considered by the Siamese the main stream. The united river still retains the name of Meiprein, and flows through Lower Laos, or Yan-shan, becoming navigable for boats at Xang-Mai, the capital of that territory. Farther down, however, its navigation is impeded by rapids and cataracts. After being joined by the Phitsalok, it takes the name of Menam. In the flat country of Siam Proper it more than once divides itself into several streams, and falls into the Gulf of Siam by three mouths, after a course of about 800 miles. The Menam, like the Nile, annually overflows its banks, and fertilises a large district of country. Its waters begin to rise in the month of June, and in August they overflow the banks to a height sometimes exceeding six feet above their ordinary level. They generally remain in this state till the month of November, when they begin to subside; and by the end of December the river has returned to its natural bed. When the waters are supposed to have reached their height, the king deputes a hundred priests to command the inundation to proceed no farther. This, however, does not always succeed; and sometimes the country suffers fearfully from an extraordinary rise of the waters. During the prevalence of the inundation the country has the appearance of one vast lake, and boats traverse it in all directions. The valley of Menam is estimated to be about 450 miles in length, with an average breadth of about 50 miles, "constituting," says Sir John Bowring, "according to the usually received estimates, an area of above 22,000 square miles of territory, whose fertility is not exceeded by that of any portion of the globe." The principal mouth of the Menam is the eastern, on which the town of Bang-kok stands, and is the only one navigable for large vessels. The most western mouth is the Me-klong, so called from the river of that name which falls into it, and which is said to be navigable for boats for about 200 miles. The central mouth also receives a river, the Tachin, which is navigable for a considerable distance. East of the eastern mouth of the Menam is another large river, the Bang-pa-kong, which rises in the mountains of Camboja, between 15. and 16. N. Lat., and is said to carry down a volume of water not much less than the Menam itself. The plain of Siam Proper is intersected by numerous canals. In the east of Siam is Meikong, or Camboja river, one of the largest of Southern Asia. It rises in the mountains of Yun-nan, about N. Lat. 27. 20., and, flowing in a south by east direction, through Laos and Camboja, falls into the sea by three mouths, about N. Lat. 9. 35. It has a length of about 1500 miles; but its navigation is much impeded by sand-banks at its mouths. In the west the principal river of Siam is the Saluen, which for several hundred miles forms the boundary between it and Burmah. It rises in the eastern portion of Tibet, flows south through the Chinese province of Yun-nan, forms the boundary between the Burmese empire on the west, and the territories of Laos and Siam on the east, and then flows through the northern portion of the Tenasserim provinces, to its mouth in the Bay of Bengal. It has a length of probably about 800 miles, but seems to be little suited for navigation. The climate of Siam is, for a tropical region, salubrious. The Siamese suffer from those diseases common to tropical countries—fevers, diarrhœas, and dysenteries being the most fatal. Travellers who pass into the interior are very liable to the jungle fever. The year, as in other tropical countries, is divided into a wet and a dry season. At Bang-kok the dry season lasts from October to April, and during this period the weather is temperate; but in April and the beginning of May, before the rains set in,

the heat becomes very oppressive, the thermometer being as high as 95° or 96° in the shade. The rains commence early in May, and continue to September. The prevailing winds are regular, blowing at different seasons of the year from all points of the compass. About the end of September the north-east monsoon begins to prevail, whence the wind veers gradually round towards the east, south, and west.

This interesting country is particularly rich in natural productions. "In its great outlines," says Sir John Bowring, "the animal, mineral, and vegetable world resembles that of other tropical regions, though in every part of the field there are varieties in detail which belong to the domain of the naturalist. They will become in time the objects of particular attention; and no portion of the East is probably so inviting as the Siamese regions, from their extent, their richness, and their novelty. There is, indeed, almost everything to explore; and the inquirer may now 'expatiate boldly,' with a certainty of having a full recompense for his exertions and investigations." Of the geology or mineralogy of Siam little is yet known. Tin abounds, and forms an important article of export. Copper and lead are also obtained in large quantities. Antimony and zinc exist, but the ores are not worked. Silver is found in combination with copper, lead, and arsenic; and gold is obtained in many parts. Iron mines are wrought at Tha Sung by the Chinese, and the ore is said to be very rich. Precious stones abound in various parts of the country. Agriculture is in a very backward state, and their implements of husbandry are of the very rudest description. In many places the land is prepared by turning in herds of buffaloes during the rainy season, to trample down the weeds and move the soil, which is then harrowed by a coarse rake, or a bush of thorny shrubs, after which the seed is broadcast upon the surface. The most important crop is rice, of which large quantities are now exported. The annual produce of rice at present is estimated at 25,000 tons; but by improved and extended cultivation, this might be raised to 100,000 tons. "The extent of cultivable rice land," says Sir John Bowring, "is capable of being doubled or trebled; there is now only one rice harvest in a year, and there might well be two." The sugar-cane is largely cultivated, but principally under the direction of the Chinese settlers. According to the authority already quoted, sugar will probably become the most important of all the exports of Siam, the soil being particularly adapted to its cultivation. Maize is extensively cultivated, particularly in the mountainous districts. The bamboo is to the natives one of the most valuable of products, being made to serve an almost infinite variety of purposes. Siam is noted for the great variety and abundance of its fruit-trees. The whole neighbourhood of Bang-kok is one forest of fruit-trees, and the products are both various and excellent. The chief fruits are the cocoanut, banana, pine-apple, tamarind, mango, guava, orange, lemon, citron, pomegranate, mangosteen, and *durian*, a fruit of an exquisite flavour, but with a very disagreeable odour. Among the other vegetable products of the country are cotton, tobacco, sago, black pepper, cardamums, sapanwood, gamboge, and gutta-percha. The Aquila, or eagle wood (*lignum aloes*) is of great consumption as a perfume among the nations of Eastern Asia.

The elephant is very common in Siam, and here that animal is said to attain its greatest perfection, being sometimes twelve or thirteen feet in height. They are extensively used throughout the country for riding and carrying burdens, except in the capital, where their use is restricted to a few persons of high rank. The destruction of even the wild elephant is prohibited, yet many are killed surreptitiously for the sake of their tusks. Tigers abound, especially in the Laos country; and the leopard and tiger-cat are common. Of ruminating animals there are several species of deer, the goat, the ox, and the buffalo. Animals of the monkey tribe are numerous. Dogs and cats are seen in large numbers in the streets and houses of the Siamese. Bears, wild pigs, and porcupines, are common in the jungles and forests. The feathered tribes are very numerous, and range from the humming-bird to the *karien*, a species of stork as tall as a man. The reptiles of Siam are multitudinous, and include crocodiles, tortoises, lizards, serpents, &c. Of insects, the *caccus lacca* produces the gum called lac in commerce.

The population of Siam is variously given, but may be estimated at from 5,000,000 to 6,000,000. It is made up of different races, the principal of which are Siamese, Chinese, Laos, Malays, and Cambojans. The Siamese are supposed to amount to about 1,800,000, and are principally located on the banks of the Menam and tributary streams south of N. Lat. 20., and down the peninsula to about N. Lat. 7. The Laos population is estimated at about 1,000,000, and principally occupy the great valley through which the Camboja flows, between N. Lat. 13. and 21. The Cambojans, who are only about half as numerous as the Laos, occupy the southern districts of the Camboja, down to the frontiers of Cochin-China. The Malayans, of whom there are probably nearly 1,000,000, occupy the peninsula south of N. Lat. 7. The Chinese settlers in Siam are estimated at about 1,500,000. (See Bowring's *Siam.*)

The government of Siam is a pure despotism, uncontrolled by laws, ancient usages, or any form of assembly. There is, indeed, a body of laws occupying, it is said, about seventy volumes, but the king has the power of at any time superseding the ordinary course of justice. He has, indeed, absolute power over the property, liberty, and lives of his subjects. There are practically three principal tribunals for the administration of justice, those of the king, the princes, and the provincial governors; but bribery prevails in every department, and from the judge down to the lowest clerk every one has his price. The king sits in public during a certain part of one day in the week for the purpose of receiving complaints. There is a second or inferior king of Siam, who exercises a kind of secondary or reflected authority, the exact nature or extent of which does not seem to be clearly defined. He is generally a brother or near relative of the king. A characteristic feature of Siamese society is the abject submission of every inferior to all who are superior to him in the social scale. "No man of inferior rank dares to raise his head to the level of that of his superior; no person can cross a bridge if an individual of higher grade chances to be passing below; no mean person may walk upon a floor above that occupied by his betters. . . . Honours almost divine, language quite devotional, humiliations the most degrading, mark the difference between sovereign and subject; and to some extent the same reverence is paid to age which is exhibited towards authority." (Bowring's *Siam.*) A large part of the population is in a state of slavery; and every man above the age of twenty is bound to devote four months of the year to the service of the king. Public officers are often made responsible for the faults of those committed to their care; and parents are frequently made to bear a part of the punishment inflicted on their children because they ought to have taught them better. The parent has absolute power over his children, and may even sell them for slaves; but he cannot take away their life. Polygamy is legal, but there is always one wife in chief who has the pre-eminence and control over the rest. Marriage is a purely civil rite, and divorces are frequent and obtained with little difficulty.

The bonzes or priests are charged with the public education, and schools are attached to most of the religious establishments. Elementary education seems to be pretty

generally diffused among the male population, and a considerable portion of them are able to read and write; but the females are almost entirely neglected. Instruction is chiefly confined to the creeds and rites of Buddhism, and there are few means of acquiring any of the higher branches of knowledge.

The religion of Siam is Buddhism. The priests or bonzes (Siamese *Phra*) are very numerous, exceeding, it is said, a hundred thousand. They generally live in convents attached to the temples, and are relieved of all taxes or services to the king or state. Every male must at some period of his life become a candidate for the priestly office, and remain for at least three months in a monastery, after which he may return to his secular condition. At the head of the priesthood is the *Sangkharat*, or high priest, who is appointed by the king, and who always resides in the palace. His authority is supreme over all the pagodas and bonzes of the kingdom; but beyond this he has no temporal or spiritual authority. The priesthood is supported by the spontaneous offerings of the people; and their duty is to atone for the transgressions of those who bestow alms upon them. They are held in the highest veneration, and are relieved from all bodily labour. The manufactures of the Siamese are few and unimportant. In the useful arts they are much behind several of the other eastern nations. In the manufacture of gold and silver vessels they display considerable skill; and the copper and iron founders are said to be ingenious workmen. The cotton stuffs which form the ordinary dresses of the people are chiefly imported from other countries; but there is a silk stuff worn only by persons in high rank and manufactured in Siam, which the Siamese boast has never been successfully imitated elsewhere. Earthenware of a coarse quality is produced by native manufacturers, and paper is made from the bark of a tree or plant called *khri*. The preparation of leather is extensively carried on.

Bangkok, the capital of Siam, was at one time the third in point of importance among the commercial cities east of the Cape of Good Hope, being inferior only to Calcutta and Canton. A long period of bad legislation, however, totally stripped it of its importance, and when visited by Sir John Bowring in 1855, "all that remained to represent foreign trade was one English (half-caste) merchant, one Armenian, and a few Anglo-Indians from Bombay and Surat." Since the treaties with England and the United States the trade has rapidly increased, and a writer in Hunt's *Merchant's Magazine*, who was there in May 1858, states that at that time there were "sixty-five large American and European ships at the city and in the roads." An increased demand for the productions of the country has given a stimulus to exertion, and already an increase in the produce of various articles has taken place. Rice and sugar are at present the staple articles of export; but gums, sapan wood, teak wood, gamboge, pepper, cocoa-nut oil, ivory, silk, cotton, and skins are also exported. A considerable trade is carried on with China.

The Siamese average about 5 feet 3 inches in height. The face is broad and flat, with large and prominent cheek-bones; the nose small but round not flattened as in the negro, and the nostrils distended; the mouth wide, with thick but not projecting lips; and the eyes small, with outer angles slightly turned up. Their skin is fairer than that of other Asiatics beyond the Ganges; and among the higher classes a bright yellow colour, almost like gold, is imparted to it by the use of a cosmetic. Their hair is black, thick, coarse, and long; and they dye their teeth black. In character the Siamese are idle, timid, and almost passionless; servile, fond of amusements, and mercenary. Lying and deceit is common to them with other oriental nations. The Siamese annals begin about five centuries before the Christian era, with the usual amount of fable; but from the founding of the city of Ayuthia, the ancient capital of the kingdom, about the middle of the fourteenth century, they seem to be tolerably reliable. (See Bowring's *Siam*.) The first European nation that established communication with Siam was the Portuguese, when engaged in the siege of Malacca in 1511. Soon after this a considerable number of Portuguese seem to have been located in the country, and we find them rendering valuable assistance to the Siamese in their wars with the neighbouring nations. About the beginning of the seventeenth century the Dutch obtained a footing in the country, and from that time Portuguese influence gradually declined. Towards the end of the seventeenth century, a Greek sailor named Phaulcon arrived in the country, and so ingratiated himself with the king as to be appointed prime minister. He persuaded the king to cultivate friendship with European countries, and induced him to send ambassadors to the Court of Louis XIV. These arrived in France in 1684, and also visited London, when a commercial treaty was concluded with the government of Charles II. The French king, in 1685, despatched an embassy to Siam, with a view to convert the King of Siam to the Catholic faith. This not succeeding, two years later a second embassy was sent out with 500 soldiers, which also failed in its object; and soon after a revolution happening in the country, the royal family were driven from the throne, Phaulcon was murdered, and the French were expelled from the country. About 1766 the country was overrun by the Burmese, who took by assault the capital, Yuthia, and committed great slaughter.

The English seem to have had little intercourse with the Siamese till very recently. In 1822 Mr John Crawfurd was commissioned by the Marquis of Hastings, then governor-general of India, to visit Siam and endeavour to establish commercial relations between that country and India, but met with comparatively little success. In 1826 a commercial treaty was concluded with England, and a similar treaty was concluded with the United States in 1833. In 1855 Sir John Bowring visited Siam, was very favourably received, and succeeded in concluding a treaty of friendship and commerce between her British Majesty and the King of Siam. A British consul is now allowed to reside at Bangkok, and British subjects may reside permanently there or within a certain distance from that town. British vessels may trade freely at any of the seaports of Siam, and in place of the previous heavy restrictions, merchandise is now subject to slight import or export duties. A similar treaty has since been concluded with the United States. For farther information regarding Siam and the Siamese see especially Sir John Bowring's ***Kingdom and People of Siam***, London, 1857.

SIBERIA. See Russia, *Asiatic*.

SIBYLS (Σίβυλλα, *Sibylla*, said to be derived from Διὸς and βουλή, signifying ***the counsel of Zeus***), in pagan antiquity, certain women said to have been endowed with a prophetical spirit, and who delivered oracles, showing the fates and revolutions of kingdoms. Their number is unknown. Plato speaks of one, others of two, Pliny of three, Ælian of four, and Varro of ten; an opinion which is universally adopted by the learned. These ten Sibyls generally resided in the following places: Persia, Lybia, Delphi, Cumæ in Italy, Erythræa, Samos, Cumæ in Æolia, Marpessa on the Hellespont, Ancyra in Phrygia, and Tyburtis. The most celebrated of the Sibyls is that of Cumæ in Italy, whom some have called by the different names of Amalthæa, Demophile, Herophile, Daphine, Manto, Phemonoë, and Deiphobe. It is said that Apollo became enamoured of her, and that to make her sensible of his passion he offered to give her whatever she asked. The Sibyl demanded to live as many years as she had grains of sand in her hand, but unfortunately forgot to ask for the enjoyment

of the health, vigour, and bloom of which she was then in possession. She had already lived about 700 years when Æneas came to Italy, and, as some have imagined, she had three centuries more to live before her years were as numerous as the grains of sand which she had had in her hand. She gave Æneas instructions how to find his father in the infernal regions, and even conducted him to the entrance of hell. According to the most authentic historians of the Roman republic, one of the Sibyls came to the palace of Tarquin II. with nine volumes, which she offered to sell for a very high price (Pliny *N. H.*, xiii. 28). The monarch disregarded her, and she immediately disappeared, but soon afterwards returned, when she had burned three of the volumes. She asked the same price for the remaining six books; and, when Tarquin refused to buy them, she burned three more, and still persisted in demanding the same sum of money for the three that were left. This extraordinary behaviour astonished Tarquin; he bought the books, and the Sibyl instantly vanished, and never afterwards appeared to the world. These books were preserved with great care by the monarch, and called the Sibylline verses. A college of priests was appointed to take care of them; and such reverence did the Romans entertain for these prophetical books, that they were consulted with the greatest solemnity when the state seemed to be in danger. When the capitol was burned in the troubles of Sylla, the Sibylline verses, which were deposited there, perished in the conflagration; and to repair the loss which the republic seemed to have sustained, commissioners were immediately sent to different parts of Greece to collect whatever verses could be found of the inspired writings of the Sibyls. The fate of these Sibylline verses, which were collected after the conflagration of the capitol, is unknown. There are now many Sibylline verses extant, but they are universally reckoned spurious; and it is evident that they were composed in the second century by some of the followers of Christianity, who wished to convince the heathens of their error, by assisting the cause of truth with the arms of pious artifice.

SICARD, Abbé. See Deaf and Dumb.

SICILIES, KINGDOM OF THE TWO.

The whole of this kingdom, denominated in Italian the *Regno delle Due Sicilie*, has an area of 32,530 geographical square miles, and a population, in January 1855, of 9,088,377 inhabitants. It extends in N. Lat. from 36. 38. to 42. 55., and in E. Long. from 12. 25. to 18. 30. Some of the smaller islands, however, extend far beyond these limits. It is bounded on every side by the sea, except on the N.W., where it comes into contact with the Papal States. Being situated on both sides of the Straits of Messina, it is naturally divided into two portions, which are distinguished by the official appellation, Naples, or the continental part, of *Dominî al di quà del Faro;* and Sicily, or the island part, of *Dominî al di là del Faro.*

The continental part, or *Dominî al di quà del Faro*, called also *Regno di Napoli*, comprises the southern and most beautiful half of the Italian Peninsula. It forms the ankle, spur, heel, and foot of the boot (*lo Stivale*) to which the configuration of Italy is often compared. It extends in N. Lat. from 37. 55. to 42. 55, and in East Long. from 13.15 to 18.30., and has an area of 24,971 geographical square miles, and a population (in January 1855) of 6,857,357 inhabitants. It is bounded on the N.W. by the States of the Pope, on the W., as far down as the Straits of Messina, by the Tyrrhenian, on the S.E. from the Straits to the Cape of Leuca, by the Ionian, and on the N.E. by the Adriatic Sea. The frontier line on the N.W., nearly the same as it was at the foundation of the monarchy in 1130, is, with its windings, about 185 miles, and in a direct line 105 miles long. It extends from the north bank of the river Tronto, on the Adriatic, across the chain of the Apennines, to the small stream of San Magno near Portella, on the Tyrrhenian Sea, 2 miles east of Terracina.

The length of the kingdom from the Tronto to the Capo dell' Armi, following the curved line of the Apennines, is 350 miles; and its greatest breadth from the Punta della Campanella, opposite the Island of Capri, to Brindisi, on the Adriatic, from W. to E., is about 200 miles. South of that line it becomes very narrow; from the mouth of the Crati, on the Ionian, to Cirella, on the Tyrrhenian Sea, it is not more than 29 miles; and only 16 miles between the gulfs of Sta. Eufemia and Squillace, farther south.

The physical geography of the country is chiefly determined by the chain of the Apennines, which, by their numerous ranges, offshoots, and valleys, cover most of its surface, and greatly contribute to its variety and picturesque beauty. These mountains, which have already been described in this work under head Italy, on entering the kingdom on the N.W. from the papal territory, branch into two lofty ranges, one of which, keeping so near the Adriatic as to leave only a narrow strip of lowland along the shore, attains the greatest elevation of the whole chain in Monte Corno, called also the Gran Sasso d'Italia, 10,154 English feet, and Monte Amaro, the highest peak of the Maiella group, 8956 feet above the level of the sea. The western range, sweeping round the sources of the Aterno, forms the high peaks of Monte Velino, 7780 feet, and Monte Greco, 7875 feet, and unites again with the other in the high tableland of the Piano di Cinquemiglia, whence the main chain keeps more in the centre of the Peninsula, and at La Meta swells to an elevation of 7480 feet. From this point the main chain, in its progress southwards, keeps constantly in the centre of the Peninsula, but scatters in a confused and irregular mass over a great tract of country, and sends important offshoots east and west, till it forms the lofty central group of the Terminio, in Lat. 41 and Long. 15. 25. The Terminio is at once the boundary of the provinces of Principato Ultra, Principato Citra and Capitanata, and the watershed whence four of the most important rivers in the kingdom—the Sele, the Calore, the Sabato, and the Ofanto—begin their course. The highest peaks of this part of the chain are Monte Mileto, in the Matese group, 6745 feet, and the Terminio itself, 5680 feet.

From the Terminio the Apennines take an eastern direction, and form the lofty group between Rionero and Potenza, which divides the basin of the Ofanto from those of the Bradano and the Basento, and from near Lagopesole send south-east an offshoot, which encloses the Apulian plain, and gradually diminishing in height, ends at the Cape of Sta. Maria di Leuca. From Potenza they take a southern course, and approaching the Tyrrhenian Sea at the head of the Gulf of Policastro, swell into the high table-land of Campotanese, and the lofty group of the Pollino, which in Dolcedorme, its highest peak, attains an elevation of 6875 feet. From that group the chain, scarcely receding from the sea-shore, rises at Monte Cocuzzo to 5620 feet, forms the high table-land of La Sila, and sinks abruptly south of Tiriolo to such an insignificant elevation between the Gulfs of Squillace and Sta. Eufemia, as to have often suggested the idea of a canal across the low neck of land that separates them. Immediately to the south of that neck the mountains rise again, and form the lofty group of the Aspro-

monte, which in Montalto, its highest peak at the toe of Italy, attains an elevation of 4380 feet.

Totally detached from the chain of the Apennines, from whose nearest slopes it is separated by an extensive plain, called the Tavoliere di Puglia, rises the isolated group of Monte Gargano (*Garganus*), a lofty promontory, boldly projecting east for the length of 35 miles into the Adriatic, between the mouth of the Fortore on the north-west and the Gulf of Manfredonia on the south-east. Its highest peak attains an elevation of 5120 feet above the level of the sea.

The Apennines, as well as the Gargano, which belongs to the same geological formation, consist chiefly of limestone; primary rocks crop out, but to no great extent, in the Maiella group, among the mountains of Montecorvino, in the Pollino, &c. The group of the Aspromonte, however, is chiefly a granite mass, and in its geological character is more like the Madonia Mountains on the opposite coast of Sicily than like the Apennines.

Enclosed or in part surrounded by the Apennines, but totally distinct from them both in their geological formation and physical character, are the volcanic districts of Campania and Apulia. The former consists of the three groups of Roccamonfina, the Flegraean Fields, and Vesuvius; the latter of Mount Vulture.

The volcanic hills of Roccamonfina rise 4 miles north-east of the towns of Sessa and Teano, nearly midway between the Volturno and the Garigliano. The outer edge or circular ridge of their great crater encloses a space of 9 miles in circumference, within which are two smaller cones, the highest of which, called Montagna di Sta. Croce, is 3200 feet above the level of the sea. The lavas of Roccamonfina are easily distinguished by their colour, and their large crystals of leucite. The volcanic tufa, which is found in large deposits along the banks of the Garigliano and the Volturno, and in some of the lower valleys of the Apennines on the frontier of Terra di Lavoro, is supposed to have been emitted by this volcano. Roccamonfina has shown no signs of activity in historical times.

The Flegraean Fields comprise the country between the banks of the Lagno and the Sebeto, as well as the adjoining islands of Nisida, Procida, and Ischia. They contain numerous large and small craters, and several cones, the highest of which are—Monte San Nicola (*Epomeus*) in Ischia, 2610 feet; Monte Barbaro (*Gaurus*), 1860 feet; and Camaldoli, 1488 feet. Monte Barbaro, composed of beds of loose scoriæ and pumiceous tufa, has a deep crater of 3½ miles in circumference, enclosing a plain of great fertility, which is entered by a break on the east wall of the crater. A larger crater is that of the Astroni, which is 4½ miles in circumference, and quite unbroken. Its interior is covered with large ilexes and oaks. The Flegraean Fields, in which are the Fusaro, Lucrino, Averno, and Agnano lakes, have been active in historical times. From the south-east wall of the Solfatara crater, midway between Pozzuoli and the Lake of Agnano, a stream of lava poured forth in 1198, which crossed the ancient Via Puteolana, and reached the sea. Even at present, from the crevices within the Solfatara, steam and noxious gases constantly exhale, and flames are occasionally seen at night. From the flanks of Mount Epomeo, in Ischia, a stream of lava containing a large quantity of felspar, issued in 1302, and descended to the shore, 2 miles off. And in 1538, after a succession of violent earthquakes, on the 28th, 29th, and 30th of September, the country round Pozzuoli was convulsed by eruptions of steam, pumiceous ashes, lapilli, scoriæ, and black mud, which elevated the whole coast from Miseno to Cape Coroglio, and raised, 1½ mile west of Pozzuoli, a conical hill called Monte Nuovo, 440 feet high and 1½ mile in circumference, on the spot where the village of Tripergola and part of Lake Lucrino stood. The tufa hills, on the slopes of which the city of Naples is built, belong to the Flegraean group.

Mount Vesuvius, one of the most active volcanoes in the world, an account of which will be found in this work under head VESUVIUS, rises to the east of Naples, between the shore of the bay, on the south, and the Apennines, on the north and east. It is 30 miles in circumference, and at a certain height divides into two points; the Somma, whose highest peak, the Punta del Nasone, is 3747 feet above the level of the sea, and Vesuvius proper, which, at the Punta del Palo, on the north brim of the crater, attains an elevation of 3949 feet. The height of the eruptive cone is subject to great variations; in March 1850 it was 4235; and in June 1858 it had been lowered to 4075 feet. At the commencement of the Christian era Vesuvius was considered as an extinct volcano, and no records existed of its having burned in historical times. But under the reign of Titus, in A.D. 79, on the 24th of August, after a succession of earthquakes, which had begun some years before, a tremendous explosion took place, which is memorable as the eruption that destroyed Herculaneum, Pompeii, Stabiae, and several smaller villages on the slopes of the mountain, and caused the death of Pliny the naturalist, whose nephew, Pliny the younger, has left us an interesting account of the event. Since that time Vesuvius has not ceased to be more or less active, and till 1858 more than fifty-six great eruptions, not to count smaller ones, had taken place, of which there are historical records.

Mount Vulture rises at the west end of the Apulian plain, on the frontier of Basilicata, out of the cretaceous macigno formation of the Apennines, which surround it almost on every side. It has shown no activity in historical times; and the absence of streams of lava, coupled with the beds of travertino resting in several places on the volcanic formation, prove its very great antiquity. Its inner regions are clothed with forests, and within its widest crater there are two small lakes. It has several cones, but the central and highest peak, called Il Pizzuto di Melfi, attains an elevation of 4357 feet above the level of the sea.

The surface and physical character of the provinces vary very much. The three provinces of the Abruzzi and the adjoining province of Molise, are almost entirely covered by mountains, and high table-lands and valleys, which give them a pastoral more than an agricultural character. Some of the valleys are of great fertility, especially the beautiful valley of Sulmona, watered by the Gizio and the Sagittario; but in general they have a cold climate, and southern plants do not thrive well. Between the valley of Sulmona to the north, and the valley of the Sangro to the south is the Piano di Cinquemiglia, a high table-land about 4300 feet above the level of the sea, and surrounded by higher mountains, which enjoys the privilege of being the most wintry spot in Italy. The high road from Naples to the Abruzzi is carried through it; but the sudden snowstorms and strong winds to which the table-land is exposed make it dangerous, and often impassable in winter, and sometimes even late in the spring. On its southern end is Roccarasa, the most elevated village in Italy, being 4370 feet above the level of the sea. To the east, along the shore of the Adriatic, there is a plain extending from the slopes of the Apennines to the sea, varying from 1 to 13 miles in breadth. This strip of lowland has a mild temperature, favourable to the growth of the olive-tree, and, in some more sheltered situations, even of the orange.

The province of Terra di Lavoro is covered to the east by the lofty groups of the Mainardi, the Matese, and the Taburno, part of the main chain of the Apennines; to the north-west by an offshoot, which descends to the sea between Terracina and Gaeta; and that of Naples to the

south-east has a lofty offshoot, which forms the mountains of La Cava Castellammare and Sorrento, and enclosing the Bay of Naples to the east, ends opposite the island of Capri. Within those boundaries is the great Campanian plain, celebrated in ancient as well as in modern times for its inexhaustible fertility. Strabo calls it the richest plain in the world. Its uniformity is broken by the two volcanic groups of the Flegraean Fields and Mount Vesuvius. It has a volcanic soil, but near the foot of the mountains it is covered by a detritus of gravel, washed down by the heavy rains. The small state of Pontecorvo, belonging to the Pope, is inclosed in the Terra di Lavoro.

Principato Ultra is traversed by the range of the Apennines, which, with their offshoots, cover most of its surface. The large valley, in the midst of which the city of Avellino, the capital, is situated, is of considerable fertility; but as a whole it is a poor district. In the heart of this province is Benevento, the capital of a territory of 45 square miles belonging to the Pope. Napoleon conferred it on Talleyrand, but the Congress of Vienna restored it to the Holy See.

In Principato Citra, on the south-west, bordering the Gulf of Salerno, is a vast plain, 28 miles long, and from 2 to 12 miles broad. It is surrounded by the Apennines on all sides, except on the west, where it is bounded by the sea. To the east is the great mass of the classic Alburno (*Alburnus*), the lower buttresses of which are washed by the Sele. Four miles from the left bank of this river towards the south end of the plain, are the ruins of PAESTUM, already described in this work. The plain is at present little cultivated, and visited by malaria. The surface of the rest of the province is of a mountainous character.

Basilicata is in great part covered by the main range and numerous offshoots of the Apennines, except on the south-east, where a large and rich tract of flat country extends from the foot of the mountains to the Gulf of Taranto. This plain is watered by the Bradano and the Basento, and though at present in great part a waste, in ancient times it was the source of the wealth and prosperity of Metapontum. To the south-west there is a smaller plain, on the Gulf of Policastro, near the site of ancient *Velia*. The centre of Basilicata is the wildest, least civilized, and poorest district in the kingdom.

Nearly two-thirds of the area of the three provinces into which Calabria is divided are also of a mountainous character, especially on the western side. On the eastern shore there is a large extent of low country, a continuation of the great plain of Basilicata, watered by numerous streams, and possessing great fertility and a very mild temperature. Sybaris, Thurium, Croto, and other cities of Magna Græcia, flourished on this plain, which now is in great part deserted. In the heart of Calabria there is a vast mountain table-land called La Sila (*Sila*), about 40 miles long and from 16 to 20 miles broad, which extends through the greatest part of Calabria Citra and enters Calabria Ultra II. Its highest peaks are clothed with magnificent firs (*Pinus silvestris*), and the lower ones with oak, beeches, and elms. It is intersected by numerous ravines, and well watered by several streams, which give it excellent pasturages in summer. The forests of La Sila were well known to the ancients, and to this day supply the greatest amount of timber to the royal navy of Naples. The Piana di Monteleone, and the plain of Gioia, on the west shore of Calabria Ultra I., offer extensive tracts of rich lowland, covered chiefly with olives, oranges, and other trees of southern climates.

Capitanata, Terra di Bari, and Terra d'Otranto, which are known by the general denomination of Puglia (*Apulia*), are almost an unbroken level country, stretching from the slopes of the Apennines to the shores of the Adriatic and the Ionian Sea. The northern part of Puglia, called *Puglia Piana*, forming the province of Capitanata, and extending from the Tiferno to the Ofanto River, consists of a great plain called the *Tavoliere di Puglia* which slopes gently from the mountains to the sea, where it is bounded by the isolated group of Mount Gargano. The Tavoliere, which is about 80 miles long and 30 miles broad, belongs almost entirely to the crown, and is chiefly laid out in pasture. Its surface is covered with wild capers, and the only trees to be seen are, here and there, some wild pears. From October to May it is enlivened by about 2,500,000 sheep, which descend from the mountains of the Abruzzi and Molise, where they pass the summer months.

The south part of Puglia, called *Puglia Pietrosa*, and including Terra di Bari and Terra d'Otranto, has, on the south-west, a chain of low rocky hills, called *Le Murgie* (an offshoot of the Apennines, from which they branch off near Venosa), which divide it from Basilicata, and gradually sink into insignificance as they descend south-east to the Cape of Sta. Maria di Leuca. The flat country continues between the Murgie and the sea for more than 56 miles from the Ofanto to Monopoli, where the Murgie come so near the Adriatic as to leave only a narrow strip of lowland till near San Vito, whence to the Cape of Leuca it is but an undulating plain, with some rising ground in the centre. On the Gulf of Taranto the surface of Terra d'Otranto is also generally flat, and joins the plain of Basilicata near the banks of the Bradano.

The Neapolitan rivers, owing to the absence of tides, have no harbours of any use at their mouths, except for small boats; but they greatly contribute to the fertility of the country, and would do more so if, instead of letting them, by their overflowing, flood the country and produce marshy plains and malaria, the natural advantages they offer for a vast system of embanking and irrigation were properly turned to account. The most important of them are—

On the western coast, the Liri or Garigliano (*Liris*), which drains the valleys west of Lake Fucino, and an extensive district of the Papal States. It rises in several distinct springs from the side of a conical hill, below the village of Cappadocia, in the midst of a most wild and picturesque scenery, in the Abruzzo Ultra II. It flows at first in a south-east direction through the alpine valleys of Nerfa and Roveto, receiving several small mountain-streams, till it emerges into the open country, at Sora, where it takes a turn to the south-west, and forms a series of small cascades (*le Cascatelle*), below the *Insula Fibreni* of Cicero. On being joined by the Fibreno (*Fibrenus*), a small clear stream which issues from the Lake of Posta, it forms, 4 miles below Sora, the Falls of Isola, about 100 feet high, one of the most remarkable waterfalls in Italy. Below Isola the Liri again bends its course to the south-east, and soon after passing Ceprano receives the Sacco or Tolero (*Trerus*), its most considerable tributary, the sources of which are 40 miles higher up, in the elevated district between the Palestrina and the Lepini mountains. After this junction it takes the name of Garigliano, and on receiving, 5 miles lower down, the waters of the Melfa (*Melfis*), which rises in the flanks of the Meta, it resumes abruptly a south-west direction, and after a course of 60 geographical miles, enters the sea near the site of ancient *Minturnæ*, in the Bay of Gaeta. In the lower part of its course it is navigable for boats; and near its mouth it has a suspension-bridge, over which the high road from Rome to Naples is carried.

The Volturno (*Vulturnus*), which drains great part of ancient *Campania* and *Samnium*, rises among the Samnitic Apennines 5 miles south of Alfidena, and emerging into the Campanian plain below Venafro, follows a south-east course till it is joined by the Calore. Turning thence to the west-south-west, it flows round the walls of Capua (the ancient *Casilinum*), and after a course of 100 miles,

falls into the sea 20 miles below that city, near the village of Castel Volturno, midway between the mouth of the Garigliano and the site of ancient *Cumæ*. It is a deep, rapid, and turbid stream, and subject to sudden and great overflowings of its banks.

The Calore (*Calor*) rises in the group of the Terminio, and flowing first north and then west, after a course of 60 miles, unites with the Volturno near Caiazzo. Its two principal tributaries are the Tamaro (*Tamarus*), which rises near Boiano, in the province of Molise, and joins the Calore 5 miles above Benevento; and the Sabato (*Sabatus*), which also rises in the group of the Terminio, and taking a different course, unites eventually with the Calore, just below Benevento.

The Sarno (*Sarnus*), which drains the plain east of Vesuvius, springs as a clear and abundant stream from a perpendicular rock behind the town of the same name, and after a course of about 20 miles, falls into the Bay of Naples, 3 miles north of Castellammare. In ancient times it flowed under the walls of Pompeii, and entered the sea close to its gates. The great eruption of Vesuvius of A.D. 79, by filling up an arm of the sea, changed the course of the Sarno, whose mouth at present is two miles from Pompeii.

The Sele (*Silarus*) drains the province of Principato Citra, and has a course of 64 miles. It rises near the town of Caposele, in the group of the Terminio, not far from the sources of the Ofanto, and flows south till it receives the Tanagro (*Tanager*), a considerable stream which rises in the mountains of Lagonegro, drains the broad valley of Diano, and after a course of 30 miles, unites with the Sele, north of Mount Alburno. The Sele takes thence a south-west direction, skirts the north-west basis of the latter mountain, traverses the plain of Pæstum, where it receives the Calore, which rises among the mountains of the Cilento, and falls into the Bay of Salerno, 5 miles north of the site of Pæstum.

From the mouth of the Sele to the Straits of Messina, the range of the Apennines coming too near the Tyrrhenian shore, there are no rivers, but numerous mountain-torrents, each draining its own valley, and often dry in summer. The most important of these streams are, proceeding from north to south, the Alento, the Molpa (*Melpes*), the Mingardo, the Basento, the Lao (*Laus*), which fall into the Gulf of Policastro, the Savuto (*Ocinarus*), and the Lamato into the Gulf of Sta. Eufemia; and the Mesima and Marro (*Metaurus*), which drain the plain of Gioia and the Piana di Monteleone, and fall into the Gulf of Gioia.

The principal rivers that flow into the Adriatic are—the Tronto (*Truentus*), which divides Naples from the States of the Pope, and drains both frontiers. It rises among the mountains of Amatrice, and is navigable for boats only a few miles above its mouth. The Tordino, the sources of which are near those of the Tronto, and the Vomano (*Vomanus*), which rises in the lofty group of the Gran Sasso, empty themselves at a short distance from each other. The Pescara, which in the upper part of its course preserves its ancient name of *Aternus*, drains the whole valleys of Aquila and Sulmona, and the south-west slopes of the Gran Sasso. It rises near S. Vittorino, in the Abruzzo Ultra II., and flows south-east through a broad elevated valley more than 2000 feet high, from which it escapes into the lower valley of Sulmona, by a narrow gorge in the mountains, through which the ancient *Via Valeria* was carried. At Popoli the Aterno unites with the Gizio and the Sagittario, which descend from the Maiella group and drain the valley of Sulmona, and taking the name of Pescara and a north-east course, falls into the sea at the fortress of that name.

The Sangro (*Sagrus*) rises in the group of mountains that enclose the basin of Lake Fucinus on the south-west, and follows a south-east direction through an upland valley shut in on the north by the lofty Monte Greco. From this upper basin it emerges through a narrow gorge into a lower valley, passes under Castel di Sangro, and turning abruptly to the north-east, after a course of more than 70 miles, falls into the sea midway between Ortona and Vasto. The Trigno (*Trinius*), which has a course of nearly 60 miles from west-south-west to east-north-east, rises among the mountains of Agnone, and falls into the sea 7 miles south of Vasto. The Biferno (*Tifernus*) rises near Boiano, on the north slope of the lofty group of the Matese, and after a course of more than 60 miles from south-south-west to east-north-east, falls into the sea 4 miles south of Termoli. The Fortore (*Frento*), about 50 miles long, has its sources in the mountains of La Riccia and Baselice, and its mouth north of the Lake of Lesina, in Capitanata, opposite the group of the Tremiti Islands. The Cervaro (*Cerbalus*) and the Carapella have their sources at a short distance in the mountains of Ariano and Trivico, traverse parallel to each other the Apulian plain, and fall, the former into the Pantano Salso, and the latter into the sea, south of Manfredonia. The Ofanto (*Aufidus*), the largest of the rivers of this part of Italy, rises in the lofty group of the Terminio, about 24 miles from the Tyrrhenian Sea, and after a course of more than 80 miles, discharges itself into the Adriatic, 6 miles north of the city of Barletta. At first it flows south-east, but, checked in its course by the volcanic group of Mount Vulture, by a sudden turn north-west, sweeps round the foot of that mountain, and emerging into the Apulian plain, traverses it from south-south-west to east-north-east, as far as the sea, passing a mile below Canosa, and by the site of ancient *Cannæ*.

From the mouth of the Ofanto to that of the Bradano, a coast line of nearly 300 geographical miles, there are no rivers, and scarcely any torrents which are not dried up in summer.

The Bradano (*Bradanus*), which separates the provinces of Basilicata and Terra d'Otranto, issues out of the small Lake of Pesole, 5 miles south-east of Atella, and draining an extensive hilly tract of Basilicata, falls into the Ionian Sea north of the site of ancient Metapontum. The Basento (*Casuentus*), the sources of which are near those of the Bradano, the Salandrella (*Acalandrus?*) the Agri (*Aciris*), and the Sinno (*Siris*), all rise on the east flank of the Apennines in their progress from Potenza towards the Gulf of Policastro, and flowing nearly parallel to each other from north-west to south-east, especially in the latter part of their course, discharge themselves at a short distance of each other into the Gulf of Taranto.

The Crati (*Crathis*), the largest river of Calabria, rises in the table-land of La Sila, a few miles south of Cosenza, under the walls of which it flows, and after a course of 64 miles, discharges itself into the Gulf of Taranto, midway between Capo Spulico and Capo del Trionto, to the south of some ruins which mark the site of *Thurii*. At first it flows due north, but after its junction with the Mucrone, which drains the western Sila, it turns abruptly to the north-east, and finally due east till it falls into the sea. Three miles above its mouth it receives the waters of its principal tributary, the Coscile (*Sybaris*), a considerable stream that rises in a wooded dell below the west flanks of the Pollino, and drains the north frontier of Calabria. In ancient times the Sybaris had a separate outlet into the sea. South of the Crati, the Neto (*Neæthus*), remarkable for the rich pastures of its banks, is the only other stream of any consequence as far as the Straits of Messina. It rises in the east flank of the Sila, and falls into the Ionian Sea 9 miles north of Cotrone.

The Lake Fucino (*Fucinus*), called also Lake of Celano, from the city of that name on its north-east shore, is the

largest lake of the kingdom. It is embosomed in the high Apennines of the Abruzzo Ultra II., at an elevation of 2230 feet above the level of the sea, and has a circumference of 35 miles, and an area of 36,315 acres. Its deepest part in 1853 was 53 feet, but it is subject to great rises and falls. Its shores are often frozen in winter, but the lake itself is known to have been frozen only five times since the twelfth century. Numerous small streams flow into it, but there is no visible outlet. The Romans made several attempts to relieve the towns on the shores from its destructive inundations, till at length the Emperor Claudius caused an emissary to be constructed at his own expense, on condition of getting from the *Marsi* the land reclaimed by the drainage. To this effect a tunnel 3 miles and 788 yards long was cut under Mount Salviano and the Campi Palentini, partly through a solid calcareous rock, and partly through a loose slaty marl, by means of which the waters of the lake were conveyed into the Liris, at the head of the valley of Roveto, below the modern village of Capistrello. This tunnel was aired by numerous perpendicular shafts along its course. Having been choked up during the middle ages, the Neapolitan government in 1826 undertook to repair it; but the works had little advanced in 1852, when the government granted all the lands that can be reclaimed by drainage to a company, who are now carrying out the works, the estimate of which is set at L.217,000.

The Lake of Scanno, situated among the mountains that enclose the valley of Sulmona on the west, in the Abruzzo Ultra II., is about 5 miles in circumference, and one of the most sequestered and finest lakes in Italy; it discharges its surplus water by means of the Sagittario, a tributary of the Pescara. The Lake of Fondi (*Lacus Fundanus*), between the town of that name and the sea, in the Terra di Lavoro, near the Papal frontier, is about 7 miles in circumference, but very shallow and marshy. The small lakes of Matese and Telese are in the same province; the former, on the summit of the Matese mountains, is 3 miles in circuit, and well stocked with trout; the other, at the south-west foot of the same group, is a pool, which renders the neighbourhood unhealthy by the exhalation of sulphuretted hydrogen.

In the district of Pozzuoli, near Naples, are several small lakes which, with the exception of Patria and Licola, are evidently of volcanic origin. The Lake of Patria (*Literna Palus*), a lagoon near the shore, 7 miles south of the mouth of the Volturno, is formed by the Lagno (*Clanius*), a sluggish stream which rises near Avella, and drains part of the Campanian plain. On its shore was *Liternum*, where Scipio Africanus had a villa in which he died in voluntary exile 184 B.C., ordering that on his tomb should be inscribed, *Ingrata Patria, ne ossa quidem mea habes.* The name of Patria was derived from a fragment of this inscription built into the walls of a martello tower, hence called *Torre di Patria.* On the same shore, a few miles south, is Licola, a small marshy lake, supposed to have originated with a canal begun by Nero to connect Lake Avernus and the Tiber.

The Lake Fusaro (*Acherusia Palus*) between Cape Miseno and the site of *Cumæ,* of which it was once the port, is supposed to be the crater of an extinct volcano. A sandy bar separates it from the sea, with which it communicates by a canal. It has brackish water, and is now famous for its oysters. Two miles from the Fusaro, at the bottom of the Bay of Baiæ, is the Lucrino (*Lucrinus*), now a narrow marsh filled with reeds, and protected from the encroachments of the sea by a dyke of remote antiquity. Formerly it was larger and deeper, and supplied the Roman epicures with oysters and mussels—

> "Murice Baiano melior Lucrina peloris,
> Ostrea Circeis."—Hor. *Sat.* ii. iv. 32.

But the volcanic eruption of September 1538 filled up one half of it by the formation of Monte Nuovo. About half a mile from the Lucrino, and west of Monte Nuovo, is Lake Averno (*Avernus*), 1½ miles in circumference, 4 feet above the level of the sea, and about 250 deep. It is clearly the crater of an extinct volcano, and is embosomed among steep hills of volcanic tufa on all sides except the south, where it communicated formerly with the Lucrino by a canal cut by Agrippa, who converted the two lakes into a port (*Portus Julius*) for a portion of the Roman fleet, which gave in it a representation of the naval battle of *Actium,* in the presence of Augustus. This canal was also filled up by the eruption of Monte Nuovo, but since 1857 the government has begun to re-open it with a view of converting Lake Averno into a great wet-dock, in which part of the royal navy might be safe from an attack. The poisonous qualities ascribed to Lake Avernus no longer exist.

> "Quam super haud ullæ poterant impune volantes
> Tendere iter pennis. Talis sese halitus atris
> Faucibus effundens, supera ad convexa ferebat:
> Unde locum Graii dixerunt nomine Avornum."
> —Virg. *Æn.* vi. 239.

Water-fowl are seen upon it in winter, and its fresh waters, in which men bathe with impunity, are well stocked with tench and other fish. On its shores there are several remains, the most interesting of which are—on the east side, a large ruin, octangular externally and circular within, more than 100 feet in diameter, and called the Temple of Apollo, but supposed to have been a Hall of Baths; on the south side, a tunnel called the Cave of the Sibyl (*Grotta della Sibilla*), cut through the tufa cliffs, probably by Cocceius under Agrippa's orders, to open a shorter and covered communication between the Lucrino and the Averno.

The Lake of Agnano, 2 miles north-east of Pozzuoli, is 3½ miles in circumference, and enclosed by volcanic hills. It is a source of malaria to the surrounding district, especially in summer, when large quantities of hemp are steeped in its waters. As neither the lake, nor the crater in which it is placed are mentioned by any of the Roman authors, it is thence inferred that they must have been formed by some volcanic changes during the dark ages. On the south-east bank of the lake is the celebrated *Grotta del Cane,* so well described by Addison, who visited it in the beginning of the last century. It is a small aperture at the foot of the hill, resembling a cellar, from the floor and sides of which there is constantly exhaling carbonic acid gas, which from its greater specific gravity rises only to a certain height, leaving the upper part of the cave free from its effluvia. Addison found that a pistol could not go off at the bottom of the cave, and that animal life of any kind was extinct in a few minutes. The grotto has received its name from experiments being generally practised upon dogs.

The lake, or rather pool, of Ansanto (*Amsanctus*) is worth noticing merely for its celebrity,—

> "Est locus, Italiæ in medio sub montibus altis,
> Nobilis, et fama multis numeratus in oris,
> Amsancti valles." Virg. *Æn.* vii., 563.

It is placed in a deep crater-like valley, among limestone hills, 2 miles S.E. of Frigento, in the province of Principata Ultra, and consists of two ponds, the largest of which is only 160 feet in circuit, and 7 feet deep. The water is dark and muddy, and from the carbonic acid gas and sulphuretted hydrogen that is constantly escaping, it appears to be in violent ebullition, though its temperature little exceeds that of the surrounding atmosphere. Near it are seen bones of birds, arrested on their wings in crossing the valley by the noxious exhalations.

The Lake of Lesina, at the N.W. foot of Mount Gargano, close to the right bank of the Fortore; the Lake of

Varano, at the N. foot of the same mountain; the Pantano Salso, close to the sea-shore, 3 miles S. of Manfredonia; and Lake Salpi, 5 miles further S.E. along the coast, all in the province of Capitanata, are the other lakes of any size. The Lake Salpi (*Palus Salapina*), 11 miles long and 2 broad, is of salt water, and has an artificial outlet by a canal through the low sandy bank that separates it from the sea. On its western shore stood *Salapia*, an important city of *Apulia*, of which the lake is supposed to have been the port. The lakes of Posta, 4 miles E. of Sora, in the Terra di Lavoro; Dragone, near Volturara, in Principato Ultra; and Pesole, and Serino (*Lacus Niger*), in Basilicata, are so small as to require no particular notice.

The Two Sicilies possess a larger extent of sea-coast than, with the exception of Great Britain, any other country in Europe. The most productive parts of the kingdom, as well as the most densely inhabited, are near the coast; and in surveying it the most interesting recollections of classical history are revived. In the continental part there are 1134 miles of coast, of which 392 are washed by the Tyrrhenian, 374 by the Ionian, and 368 by the Adriatic Sea.

The whole Tyrrhenian coast is for the most part bold and rocky, and though ill furnished with good harbours for large vessels, has several projecting headlands, deep indentations, and capacious bays affording a good anchorage. Of these bays the most northern is that of Gaeta (*Sinus Caietanus*), shut in on the north by the projecting headland on which the city and fortress of Gaeta are situated. It is capacious, with good anchorage ground at a depth of from 12 to 14 fathoms at the north-west end of the citadel. Gaeta is the strongest fortress in the kingdom; in 1798 it was disgracefully surrendered by the Swiss General Tschudy to the French, who, in their turn, surrendered it to the Bourbons in 1799. In 1806 it sustained a memorable siege, well known from the operations of our navy in support of the besieged against the French. Since 1848 its fortifications have been so much extended and strengthened as to render it one of the strongest places in Italy.

South and south-west of Gaeta, at a distance from 28 to 36 miles, are the small islands of Palmarola (*Palmaria*), Ponza (*Pontia*), Zannone (*Sinonia*), Ventotene (*Pandataria*), and San Stefano. They are all of volcanic origin, except Zannone, which is of limestone, covered by trachyte. Ponza, the largest, is 12 miles in circumference. At San Stefano, the smallest, there is the Ergastolo, or prison for life, for state as well as common criminals.

The next bay to the south is that of Naples, generally considered as one of the most beautiful and interesting in the world. The Greeks called it *Crater*, on account of its form, a name still given to it by the local hydrographers. At its entrance are the islands of ISCHIA and PROCIDA to the north-west, and the island of CAPRI to the south-east, which are all described under their respective heads. Its width from Ischia to Capri is 14 miles, and its depth from W. to E. 16 miles; its circuit from the Capo della Campanella on the S.E., to the Capo di Miseno, on the N.W., is more than 30 miles, and nearly 48 if the islands are included. The head of the bay washes the foot of Vesuvius. On its west side, the low range of volcanic hills which end in the promontory of Posilipo, form the two inner bays—of Naples on the east, and of Pozzuoli on the west. The latter includes the smaller sheltered Bay of Baiæ, and is bounded to the south-west by the Cape of Miseno. The Bay of Baiæ has a hilly and sterile coast of volcanic tufa, and being subject to malaria, is nearly deserted. Yet in ancient times all its shores were thickly inhabited, and covered with towns and magnificent villas belonging to the wealthy Romans, who preferred Baiæ to any other residence in the world.

"Nullus in orbe sinus Baiis prælucet amœnis."—*Hor. Ep.* i., i, 83.

The whole shore is covered with ruins, in several places advancing into the sea, upon which the Patrician villas had encroached.

> "Marisque Baiis obstrepentis urges,
> Summovere littora,
> Parum locuples continente ripa."—*Hor.* Od. ii., 17, 17.

In the tufa of the promontory of Miseno are excavated vast caverns, supposed to have been magazines for the Roman fleet stationed in a port sheltered by the Cape, three piers of which are still to be seen under water on the opening into the inner basin called Mare Morto. On the Cape itself are vast remains of a theatre and other buildings. The Bay of Baiæ offers very safe and sheltered anchorage.

In rounding the small island of Nisida and the Cape of Posilipo, the inner Bay of Naples opens to the eyes with its shores thickly dotted with buildings and gardens. The city of Naples presents itself rising in the form of an amphitheatre from the sea-shore to the slopes of the surrounding hills, and, beyond the city, a vast plain, richly cultivated and watered by the winding little stream Sebeto. On the eastern side of the bay, Vesuvius, with its double summit, rises in majestic solitude from the plain, clothed with rich vegetation to about one-half of its height, and the other half barren and furrowed by streams of basaltic lava. Along its base and on its sides are scattered numerous villages and villas built on streams of lava, which successive eruptions of ashes and pumiceous fragments have covered with the most fertile of soils. On the sea-shore, at the south-west foot of Vesuvius, 4 miles from Naples, are the large villages of Portici and Resina, built over ancient HERCULANEUM; 6 miles further east was POMPEII. Both cities being described in this work under their respective heads, we abstain here from any further notice of them. The harbour of Naples is three or four fathoms in its deepest part; it is protected by a mole that makes it safe for ships once within it, but after a S.W. gale it is not easy to enter it. The anchorage of men-of-war is outside the mole, about 1 mile S.S.E. of the light-house, where there is a depth of from 25 to 38 fathoms. Ships can be conveniently supplied with water at the mole.

At the furthermost eastern recess of the bay, where the coast suddenly bends west, is the town of Castellammare, built on the lower slopes of Monte Santangelo, and along the sheltered beach of a small bay, bounded on the N.W. by Capo Bruno, and on the S.W. by Capo Orlando. It arose from the ruins of Stabiæ, which was destroyed by the eruption of Vesuvius of A.D. 79. The port, with four fathoms of water, and protected by a mole, is secure, and contains the dockyards in which the largest ships of the royal navy are built. The S.E. boundary of the Bay of Naples is formed by the mountains that from Castellammare extend to the Capo della Campanella, which is divided from the island of Capri by a canal 4 miles broad, and from 60 to 80 fathoms deep, but exactly in the midst of which there is a sunken rock. The highest peak of this range is Monte Santangelo, south of Castellammare, 4722 feet. The town of Vico, Sorrento with its orange and citron groves, and numerous other villages, are on the north slopes of this range.

After passing to the south the island of CAPRI, we find the Gulf or Bay of Salerno (*Sinus Pæstanus*), which extends from the Punta della Campanella to the Punta di Licosa (*Promontorium Posidium*), about 46 miles across, and has a depth of 30 miles. From Campanella to Salerno, a distance of about 20 miles, the coast is bold and rocky, and dotted by numerous villages, of which the largest are Positano and Amalfi. The latter place was once celebrated for the trade of the Levant, which made it populous and wealthy. It was the birth-place of Flavio Gioia, who, in the beginning of the thirteenth century, either invented or perfected the mariner's compass. It is now a poor town of about

 5000 inhabitants; but nothing can surpass the romantic beauty of its situation on the sea-shore, at the entrance of a narrow gorge between high mountains, crowned by the ruins of its former castles. Salerno, which gives the name to the bay, stretches along the beach, with a ruined castle on a hill behind it. The road is much exposed to south-westerly winds; but there is a mole, behind which small vessels may find shelter. From Salerno the coast continues with a smooth sandy beach, and almost in a straight line south, bordering the plain of Pæstum to Agropoli, where the hills of the Cilento approach the sea and form the headland of Licosa, the southern boundary of the bay, opposite to which, separated by a narrow channel, is a small island of the same name (*Leucosia*).

From Licosa the coast trends towards the south-east, with no good port till it reaches the safe anchorage formed by the headland which, by the name of Palinuro, reminds us of the pilot of Æneas:—

"Et statuent tumulum, et tumulo solemnia mittent;
Aeternumque locus Palinuri nomen habebit."—*Æn.* vi., 380.

Midway between Licosa and Palinuro, 2 miles from the mouth of the Alento, are the scanty remains of *Velia*, where Zeno founded the eleatic school of philosophy. The mildness of its climate attracted the Romans; Paulus Æmilius was ordered there for the sake of his health. S.S.E. of Cape Palinuro the coast continues bold to Capo degli Intreschi, where it opens into a gulf (*Sinus Laus*), which takes its name from Policastro (*Buxentum*), situated on its north shore, once a place of importance, but since its sack by the Turks in 1544 a miserable village. Eight miles S.E., at the head of the gulf, is the small anchorage of Sapri (*Scidra*), from which the coast, descending south, becomes bolder and more picturesque, and is clothed with vineyards, olives, mulberries, and orange groves, and scattered with villages and towns, of which the most important are Scalea, Diamante, Belvedere, Paola, and Amantea. At Cape Suvero (*Lampetes*), it opens into the Gulf of Sta. Eufemia (*Sinus Terinæus*), and becomes flat and marshy, and infested with malaria. A few miles east of the mouth of the Lamato, on a small isolated hill, is the town of Maida, the scene of the victory gained by our arms under Sir John Stuart over the French, under General Regnier, on the 4th July 1806. At Pizzo the coast rises again, and continues rocky and inaccessible round Cape Zambrone and Cape Vaticano, till it sinks into the low coast that encloses the Gulf of Gioia (*Sinus Bruttius*), on the N. and E. The lower spurs of the Aspromonte come near the sea at Palmi, whence the coast continues lofty and bold almost the whole way round the toe of Italy. At the southernmost end of the Gulf of Gioia is the town and rock of Scylla, where the celebrated straits called Faro di Messina are entered.

Scylla is situated on a small promontory, and is built in a series of terraces rising one above the other from the sandy bays on either side of it towards the castle, which stands on the bluff cliff at its extremity. It suffered awfully from the earthquakes of 1783, the first shocks having almost totally destroyed it. Afraid of a repetition, the old Prince of Scylla and most of the inhabitants, on the evening of the 5th February, took shelter in boats on the west beach. Towards dusk, however, another violent shock rent part of its promontory, and throwing it into the sea, caused the waters of the straits to rush back with overwhelming force on the beach, and sweep away 2500 persons. On the 6th of February more corpses were thrown back on the shore than there remained inhabitants at Scylla.

The Faro channel was depicted by the poets of antiquity in most terrific colours, but as the Athenians, the Syracusans, the Locrians, and the Rhegians, fought in it, it could not have been considered so horrible by ancient sailors as by ancient poets; though the passage through it might have been an affair of some moment with their small vessels and inexperienced seamen. Its horrors, however, have been much overcome by the progress of nautical science. Admiral W. H. Smyth, long occupied in surveying the Mediterranean, took accurate measurements by theodolite angles of the distance across this passage, at four different points. The shortest distance, from the village of Ganziri to Point Pezzo, is 3972 yards; the next in length is from Messina light-house to Point dell' Orso, 5427 yards; the next from Faro Point to the Castle of Scylla, is 6047 yards; and the last, from Messina light-house to the cathedral of Reggio, is 13,187 yards.

The currents in the straits are numerous and various. In settled seasons there is a central stream running north and south, at the rate of from 2 to 5 miles an hour, and which, though properly speaking only a current when uninfluenced by strong winds, is governed by the moon. On each shore there is a counter or returning set at uncertain distances from the beach, often forming eddies to the central current; but in very fresh breezes the lateral tides are scarcely perceptible, whilst the main one increases so as to send at intervals slight whirlpools to each shore. There is an uncertain rise and fall of a few inches in the tide, but at the vernal equinox it amounts to 18 or 20 inches. There is usually an interval of from fifteen to sixty minutes between the changes, and the tide runs six hours each way. In light breezes the current may be stronger than the ship's effort, and, by turning her round, often alarms a person unacquainted with the phenomenon, although there is no actual danger. The greatest risks, however, are occasioned by the heavy gusts of wind which at times, from the mountainous nature of the coasts, rush down the torrent-beds and prove dangerous to small vessels.

Nelson with his fleet passed through this channel; but, in attributing to him the merit of first attempting it, his biographers have overlooked, not only Ruggiero di Loria, who often passed through it, but our own Byng and the gallant Walton,[1] who had, nearly a century before, also achieved the passage.

Charybdis, which is on the Sicilian coast, will be noticed hereafter.

There is a curious aërial phenomenon in the Strait of Messina, noticed by the ancients, and called Fata Morgana by the Sicilians. Most extraordinary accounts of this singular phenomenon have been given by those who have witnessed it from the city of Reggio, but the best description of it is that given by the Domenican Minasi, towards the end of the last century, who had seen it three times in its most perfect state:—"When the rising sun shines from that point whence its incident ray forms an angle of 45° on the sea of Reggio, and the bright surface of the water in the bay is not disturbed either by the wind or the current, the spectator being placed on an eminence of the city, with his back to the sun and his face to the sea, on a sudden he sees appear in the water, as in a catoptric theatre, various multiplied objects, *i.e.*, numberless series of pilasters, arches, castles well delineated, regular columns, lofty towers, superb palaces with balconies and windows, extended alleys of trees, delightful plains with herds and flocks, &c., all in their natural colours and proper action, and passing rapidly in succession along the surface of the sea, during the whole period of time that the above-mentioned causes remain. But if, in addition to the circumstances before described, the atmosphere be highly impregnated

[1] This was the officer who, after the action between Sir George Byng and the Spanish fleet, was detached in pursuit of six sail of the line and some smaller ships, and reported his success in the following terms:—"Sir,—We have taken or destroyed all the enemy's ships and vessels on the coast, as per margin. 16th Aug. 1718," &c.

with vapour and exhalations not dispersed by the wind nor rarefied by the sun, it then happens that in this vapour, as in a curtain extended along the channel to the height of about 28 feet and nearly down to the sea, the observer will behold the scene of the same objects not only reflected from the surface of the sea, but likewise in the air, though not in so distinct and defined a manner as in the sea. And again, if the air be slightly hazy and opaque, and at the same time dewy and adapted to form the iris, then the objects will appear only at the surface of the sea, but they will be all vividly coloured or fringed with red, green, blue, and the other prismatic colours."

Admiral Smyth, however, doubts the accuracy of the description, and thinks that the imagination strongly assists these dioptric appearances, having never met a Sicilian who had actually seen anything more than the loom or *mirage* consequent on a peculiar state of the atmosphere, which he here observed many times to be unusually strong.

In the Faro of Messina, the only place of importance on the continental side is Reggio, the capital of Calabria Ultra I., well built, in a healthy spot, and surrounded by most beautiful scenery. Its climate is favourable to the cultivation of plants of both hemispheres. The environs abound in oranges, citrons, mulberries, grapes, figs, and a great variety of other fruits; the date-palm bears fruit, the castor-oil plant attains a great size, and the American aloe and cactus border the roads and supply the place of hedges.

On clearing the Faro and proceeding round to the Ionian Sea, Cape Pellaro (*Bruttium Prom.*), Capo dell' Armi (*Leucopetra*) and Capo Spartivento (*Promontorum Herculis*) are passed; the latter being the southernmost continental spot in Italy, in N. Lat. 37. 56. From thence to Cape Rizzuto the coast, always bold and rocky, forms two irregular concavities divided by a projecting offshoot of the Aspromonte, on which is the town of Stilo. In the centre of the south concavity, near the shore, are the ruins of Locri Epizephyrii, one of the most ancient cities of Magna Græcia, which had Zaleucus for her legislator, and was praised by Pindar for the hospitality, justice, and wisdom of her citizens. The town of Gerace, on a rising ground 5 miles inland, sprang from it. The north concavity, called the Gulf of Squillace, from a small town of that name (*Scylaceum*) standing on a steep rock, has several small villages and towers near the coast, but no harbour or anchoring place, except with the wind off land; the water is very deep close to the shore, but there is no secure part where vessels can find shelter, in case of finding themselves on a lee-shore with a strong gale of wind. Hence the ancient appellation of *navifragum Scylacæum* given to the gulf.

Rounding the Capes Castella, Rizzuto, and delle Cimiti (the *Tria Iapygum Promontoria* of Strabo), we find Cape Nau (*Prom. Lacinium*), called also Capo delle Colonne, from the ruins of the famous temple of Juno Lacinia that stood upon it.

"Hinc [the east entrance of the gulf] sinus Herculei, si vera est fama Tarenti
Cernitur. Adtollit se diva Lacinia contra,
Caulonisque arces, et navifragum Scylacæum."—*Æn.* iii., 551.

Six miles N.W. of Cape Nau are the port and town of Cotrone, surrounded by an unhealthy district, and remarkable only as standing on the site of *Croton*, once one of the most flourishing cities of Magna Græcia, the residence of Pythagoras, and the chief seat of his school.

Further east opens the great Gulf or Bay of Taranto, which, from the extreme points of Cape Alice (*Crimissa*) to the south-west, and Cape Santa Maria di-Leuca to the north-east, extends 66 miles across. No part of the west shore affords any harbour or shelter for a vessel with the wind blowing from the south or south-east. *Sybaris*, the earliest and one of the most celebrated cities of Magna Graecia; *Thurii*, that had among its colonists the orator Lysias and Herodotus the historian; *Heracleia*, a joint colony of the Thurians and Tarentines, and the place of meeting of the general assemblies of the Italiot Greeks; and *Metapontum*, where Pythagoras ended his days—all stood on the western shore, at present deserted, of this gulf. Taranto (*Tarentum*), in its N.W. angle, behind the small, low islands of S. Pietro and S. Paolo, was once the rival of Rome, and had an excellent port, which, becoming choked up from neglect, forms now what is called the *Mare Piccolo*, which is famous for its oysters and great variety of delicate fish. The city has a fort, and occupies the site of the ancient citadel, on a rocky isthmus, which, being cut through by Ferdinand I. of Aragon, is now an island connected with the mainland by two bridges. More than 50 miles south-east of Taranto, on a rocky island connected with the mainland by a causeway, stands Gallipoli (*Callipolis*), near to which is a roadstead, with good anchorage, within gun-shot of the town; but farther inshore the ground is rocky, and there are several shoals. The trade of this town consists chiefly in the export of oil, well known by its name. Thirty miles S.E. of Gallipoli is Cape Sta. Maria di Leuca (*Iapygium Prom.*), which marks the boundary between the Gulf of Taranto and the Adriatic; and upwards of 30 miles north of it is Cape Otranto, the easternmost point of land in Italy. Otranto (*Hydruntum*), has a port capable of affording shelter to vessels when the wind is south or south-west, but a northerly wind blows right into it. It admits vessels of 150 tons. About 40 miles north-west is Brindisi (*Brundusium*), from which the Romans usually crossed to *Dyrrachium*, the modern Durazzo, on their way to Greece. It was once the best harbour on this side of the Adriatic; but in the fifteenth century the Prince of Taranto sunk some ships in the middle of the passage to prevent his enemies from entering, and thereby formed a resting-place for sea-weeds and sand, an accumulation of which choked it up. Of late years the government has undertaken the work of clearing it up.

The coast from Brindisi proceeds north-west to Monopoli, Mola, Polignano, and Bari (*Barium*), the largest city on this side of the kingdom. It has good anchorage without, and a small haven into which vessels can enter. A new port is in progress of construction. It is a fine city, and exports large quantities of wine, oil, almonds, and soap. Beyond this are Giovenazzo, Molfetta, Bisceglie, Trani, and Barletta, all populous places, but not so flourishing as they were in the middle ages. Six miles N. of Barletta, beyond the mouth of the Ofanto, are the *Reali Saline*, the largest salt-works in the kingdom; and further north, at the bottom of the Gulf or Bay of Manfredonia, is the city of that name, founded in 1256, by Manfred, and celebrated for the excellence of its esculent vegetables.

Between Manfredonia and the boundary line towards the Papal territory there are no good ports or harbours, though there are some spots where there is tolerable anchorage. On our progress north, about 8 miles north-east of Manfredonia, on the shore at the foot of Mount Gargano, is the village and tower of Mattinata, supposed to mark the spot where Archytas of Tarentum was shipwrecked. Viesti, in the midst of orange groves on the slope of the easternmost spur of the Gargano, has a fair anchorage. On rounding the promontory, the Tremiti islands (*Diomedeæ*) come in view, the nearest of which is about 14 miles from the coast. They are four—S. Domenico, S. Nicola, Caprara, and Pianosa. The latter, which scarcely belongs to the group, is 11 miles north-east of Caprara. At San Domenico (*Trimerum*), the largest, Julia, the granddaughter of Augustus and wife of Lepidus, died in exile. On S. Nicola there is a prison for culprits from Naples.

North of the mouth of the Biferno is Termoli, the second port of the kingdom on the Adriatic, sheltered by a small headland, and affording safe anchorage. North-west of Termoli there are several towns and villages, along a coast generally low and sandy. The most important of them are—Vasto (*Histonium*); Ortona (*Orton*), on a projecting promontory commanding an extensive view of the coast, and with a small port from which the best wines in this part of Italy are exported; Pescara, the second fortress in the continental states, in a most unhealthy situation at the mouth of the river of that name; and Giulianova, where the Apennines come so near the coast as to leave only a narrow strip of lowland. Ten miles north of Giulianova is the Tronto.

The *Domini al di là del Faro*, or island part of the kingdom, comprises Sicily, the Lipari group, and other smaller islands.

Sicily (*Sicilia, Sicania, Trinacria*), next to Sardinia, the largest, and by far the richest and most important island in the Mediterranean, extends in N. Lat. from 36. 38. to 38. 18., and in E. Long. from 12. 25. to 15. 35, and has an area of about 7967 geographical square miles, and a population, in January 1855, of 2,231,020 inhabitants. It is separated from the continental Italian coast by the Straits of Messina, and from the headland of Cape Bon, in Africa, by 80 miles of the Mediterranean Sea. The appearance of the two coasts justifies the belief, that a violent disruption or subsidence of strata separated it from Italy at some remote period.

The name Trinacria was derived from its form of an irregular triangle, of which the shortest side faces the east, and the longest the north. The angles of the triangle are formed by Cape Torre di Faro (*Pelorus*) to the N.E.; Cape Boeo (*Lilybæum*) to the W.; and Cape Passaro (*Pachynus*) to the S. Though the topography of the island is not accurately known, no scientific survey of it having ever been made, yet the distance, in a direct line from Cape Boeo to Torre di Faro, the greatest length of the island, is estimated at about 198 miles; from the latter Cape to Cape Passaro, its breadth, 123 miles; and from Cape Passaro to Cape Boeo, 184 miles. Its circumference, including the windings of the coast, is estimated at upwards of 550 miles.

A considerable part of the surface of Sicily is rugged, and covered with mountains. The group of Mount Madonia (*Nebrodes*), whose highest peak rises to an elevation of 3765 feet, is the central nucleus from which the other mountains branch off. The western range surrounds the Bay of Palermo and the Gulf of Castellammare, and forming the almost detached mass of Mount St Giuliano (*Eryx*), 2184 feet high, sinks into the sea near Trapani. Another range trends east, encircles Mount Etna on the north, and approaches the sea at Taormina, whence it turns north-east, and, under the name of Nettuno Mountains, ends at the Faro Cape. The third range trends south-east through the heart of the island, forms the elevated group on which stands Castrogiovanni (*Enna*), and thence breaking up into irregular masses of lower hills, covers great part of the south-east corner of the island. Between the two latter ranges, but entirely detached from them by intervening valleys, stands the great mass of Mount Etna, called also Mongibello, the largest and most destructive volcano in Europe. It rises on the east coast, between Catania and Taormina, and attains an elevation of 10,874 feet, which, however, is subject to variations, in consequence of the changes caused by great eruptions. Its base has a circumference of upwards of 90 miles, of which no less than 30 are of sea-coast, formed by the streams of its lava. A more detailed account of ÆTNA will be found under its head in this work. At the south end of its base is the rich plain of Catania, and beyond it is an extensive volcanic formation, of a much older date than Ætna, which covers the tract from Palagonia and Scordia to Palazzolo and the neighbourhood of Syracuse.

The ranges of mountains we have noticed form three great natural divisions of the island—the Val Demona, on the north; the Val di Noto, on the east; and the Val di Mazzara on the south-west side; and till 1819 they combined with the administrative divisions, which at that time were altered and changed into seven provinces. The surface of Val Demona and Val di Noto is chiefly hilly and rugged, whilst Val di Mazzara is an undulatory plain, sloping gently from the mountains to the sea.

The rivers of Sicily are numerous, but none of them of any importance; most of them are mere mountain-torrents, nearly dry in summer. The most important of them will be noticed in our survey of the coasts. There is scarcely any mass of water considerable enough to deserve the name of a lake. The largest, however, is the Lake of Lentini (*Herculeus Lacus*), between the city of that name and Scordia, south of the Piana di Catania. A few miles south of Castrogiovanni is Lake Pergusa (*Pergus*), about 4 miles in circumference, which is associated with the mythological story of the rape of Proserpine.

> "Haud procul Enneis lacus est a moenibus altæ,
> Nomine *Pergus*, aquae. . . . . .
> Frigora dint rami, Tyraos humus humida flores;
> Perpetuum ver est. Ov. *Metam.*, v., 385.

The lakes of Camerana, Terranova, and Naftia, are mere ponds.

The first appearance of the coast of Sicily is strikingly picturesque. Vessels from the westward generally touch first at Cape St Vito, the northernmost point, in N. Lat. 38. 13. and E. Long. 12. 45. It forms the west point of the Gulf of Castellammare (*Sinus Segestanus*), an indentation about ten miles in depth, at the bottom of which is the town of the same name, in a highly cultivated district. Six miles south of it, inland, are the well-known remains of *Segesta*, consisting of a Doric temple, with vestiges of an ancient theatre. To the eastward of the Gulf of Castellammare, beyond the lofty promontories that bound it on that side, is the bay and city of Palermo (*Panormus*), sheltered on the east by Mount Catalfano. There is good anchoring ground in almost every part of this bay, near the shore. To the north-east of the city is a fine mole, nearly a quarter of a mile in length, extending into water of the depth of 9 or 10 fathoms; and it forms a noble port, capable of containing a great number of vessels. Along the whole, at the most favourable points, there are establishments for the tunny fisheries. The next point on the coast is Cape Zaffarana, which looks like an island, and forms the western boundary of the extensive bay of Termini, in the middle of which stands the city of Termini. During two-thirds of the year the anchorage is so exposed that the boats must be drawn up upon the beach.

Five miles to the eastward of Termini is the site of the ancient *Himæra*, the birth-place of the poet Stesichorus, and celebrated on account of one of the most disastrous battles that history has recorded. 300,000 Carthagenians under Hamilcar were routed with great slaughter by Gelon of Syracuse and Theron of Agrigentum, B.C. 480. Near to it the Fiume Grande (*Himera*) discharges its waters into the sea, through one of the most unhealthy, but most fertile districts of the island.

About 12 miles to the east stands the city of Cefalù (*Cephalædium*), on a low projecting point of land, under a conical mount, on the summit of which are the ruins of an ancient Phœnician edifice and a Saracenic castle. It has a fine cathedral. The district from Cefalù to Caronia (*Calactæ*) is the most extensively wooded with oak, elm, and ash trees of any in Sicily, and most of the trees are converted into charcoal. On the shore there is good an-

chorage, which continues by the towns of Santa Agata and San Marco, to Cape Orlando. Here is a dangerous reef of rocks; but between it and the shore there is good ground, where small vessels may anchor in safety. Cape Orlando (*Agathyrnum Pr.*) is distinguished by the Brolo Castle, a ruinous structure, and a rock between 16 and 17 feet in circumference, and 20 feet above the level of the water, behind which a ship may ride in safety, except when a southerly wind blows with great violence.

Next to Cape Orlando is Cape Calava, which bounds on the west the Bay of Patti, a perfectly safe anchorage in all parts except in the centre, where there is a large rock; but as it appears above water, all danger is easily avoided. In the middle of the bay is the lofty projecting headland of Cape Tindaro, on which the ancient *Tyndaris* was situated. East of it a sandy beach extends along a fertile plain studded with villages, and terminates at the promontory and city of Milazzo, the ancient *Mylæ*, situated on the southern part of the promontory facing the east. It consists of the upper and lower town, and a citadel commanding the city, the port, and the promontory. This northern coast terminates with Cape Rasaculmo, which is a deep sandy bay, with several small streams running into it. The banks are much infected by malaria, but the heights near them are thickly peopled. Off the cape is good anchorage ground, with from 12 to 20 fathoms depth of water.

The eastern coast of Sicily begins at the north with the Faro of Messina, and the city of that name. The celebrated vortex known to the ancients as *Charybdis*, but now called Galofaro, is formed at the back of the tongue of land named Braccio di San Raniere, which is one arm of the harbour of Messina. This whirlpool was said by the ancients to swallow up ships, and upon the return of the tide to throw them up again in broken pieces. Admiral Smyth describes it as an agitated water from 70 to 90 fathoms in depth, circling in quick eddies, which seem to be caused by the meeting of the harbour and of the lateral currents with the main current; the latter being forced over in this direction by the opposite point of Pezzo. The risk is proverbial; and at the present day small craft are sometimes endangered by it, and ships of war wheeled round upon its surface; but, with caution, very little danger or inconvenience is to be apprehended from it, especially since a lighthouse has been constructed.

In our progress westward, along a bold and fine coast, are Cape Grosso, Point St Alessio (*Argenum*), and Cape St Andrea, near to the last of which, in a bay of the same name, is the city of Taormina (*Tauromenium*), in one of the finest situations in the world, though at present not very healthy. It has good anchorage ground, in water from 8 to 30 fathoms in depth. About 2 miles beyond it, the Alcantara (*Onobalas* or *Acesines*), one of the most considerable rivers of Sicily, falls into the sea. Near to this is the most fertile district of Mascali, which, amongst other productions, yields annually about 90,000 pipes of excellent wine.

Beyond this, at the distance of 5 miles, is Point Tocco, a precipitous mass of basaltic lava, converted into a mole, and forming a small port called the Marina of Aci. Not far from it is the city of Aci Reale, standing on extensive streams of lava. It is in a healthy and fertile spot, and is clean and well built. Another promontory, 3 miles from it, Cape Molino, is formed of lava; and the town of La Trezza, near to it, is built wholly of that rock, the very dark hue of which, contrasted with the white-washed lintels and door-posts of the houses, has a singular appearance. Near La Trezza are the rocks called the *Cyclops*, which have a bold and striking appearance; for the basalts that form them are mostly vertical, and consist of prisms of from 4 to 8 sides.

The bay upon which Catania stands is $7\frac{1}{2}$ miles in extent from La Trezza to Cape Santa Croce; the ground is generally clean, and ships may anchor in any part of it during the fine season. The city, originally a Greek colony, has been most dreadfully ravaged by wars, earthquakes, and volcanic eruptions. By the great eruption of Etna, in 1693, which in great part filled up the port, more than 50,000 persons perished, and the whole of the buildings were destroyed, except a few which were subsequently taken down to carry on the plan laid down for rebuilding the new city. It stands close on the sea-shore, and is well built, regular, spacious, and handsome. The churches and other public buildings are magnificent, being for the most part constructed of lava, faced with magnesian limestone, and enriched with marble. It is the residence of many of the Sicilian nobility, and has many literary and charitable institutions. The environs are fertile and well cultivated. The harbour is generally filled with small craft, which repair to it for corn, macaroni, potatoes, olives, figs, silk, wine, almonds, cheese, oil, soda, manna, cantharides, amber, snow, and lava. The beauty of the situation exceeds all power of description. The city, close on the sea-shore, is overshadowed by the gigantic majesty of Ætna, whose summit is only $14\frac{1}{2}$ miles northward, and is encompassed by the several minor volcanic hills, which appear like so many branches arising from the parent stock; whilst the placid brilliancy of the sea-view in front, and the solemnity of the inland scenery behind, contribute to form as magnificent a prospect as any part of the island can exhibit.

A little to the south of Catania the Giarretta (*Symæthus*), the most important river on the eastern coast, enters the sea; and further south is the port of La Bruca, with a harbour looking like a work of art rather than of nature, as the rocks rise vertically to the height of 40 or 50 feet. After passing Capo Santa Croce, the spacious Bay of Augusta (*Xiphonius Portus*), bounded on the south by Cape Magnisi (*Tapsus*), opens to view. On a tongue of land projecting from the N. side of the bay stands the town of Augusta, whose inhabitants subsist chiefly by collecting salt from some salines near them, and by the export of oil and wine. There is a fort and a lighthouse, which, with the cathedral, form the marks for reaching the anchorages; the latter are good, although the inner one is deemed unhealthy. The western sides of the harbour are watered by several streams abounding with fish. On the same side are the mountains of Hybla, celebrated by the ancients on account of the honey produced on them, the sale of which still forms a most profitable trade.

The next place to Augusta is Syracuse, originally a Corinthian colony, and the birth-place of Empedocles, Theocritus, and Archimedes. In the days of its prosperity and power it is said to have contained half a million of inhabitants. The whole of the present city now scarcely covers the island of Ortygia. It suffered most dreadfully by an earthquake in 1693, which destroyed a great part of the population. It is a fortress of considerable strength; and the entrance of the harbour, which is half a mile wide, is defended by a fort on the south of the town. The adjacent country being copiously irrigated, and possessing a marly soil, is exuberantly fertile, producing wheat, oil, hemp, tobacco, fruit, pulse, and several kinds of delicious wines; but, from the marshes of the alluvial plains on the west side, pernicious and destructive miasmata have frequently arisen. The port is a very secure one, easy of access, and sufficiently capacious to admit a large fleet, with great facilities for shipping provisions and water, as was experienced by Lord Nelson, who, in five days, obtained supplies sufficient for his memorable pursuit of the French fleet in the year 1798.

Between Syracuse and Cape Passaro, the southernmost spot in Sicily, is the extensive bay, the northern point of

which is Cape Lungo. In the whole of it there is good shelter for large as well as small vessels, which may be compelled to bear up in the channel of Malta by a westerly gale of wind. The anchorage is good in from 9 to 30 fathoms of water, with a good holding ground of stiff clay. The town of Avola carries on some traffic in wine, corn, almonds, oil, honey, and sugar made from the only plantation of canes now left on the island. The city of Noto, within four miles of the shore, is finely situated and well built, and the country around is fertile. Seven miles south of it is the Abisso, the ancient *Helorus*, which winds through a rich but unhealthy plain.

That part of the coast of Sicily which extends from Cape Granatola in the west, to Cape Passaro in the east, is generally low and arid, and does not possess a single harbour for large ships, although there are several tolerable summer anchorages. The approaches towards the headlands are not so clear nor so deep as those of the northern shores; but ships are safe which by day are not in less than 12 fathoms water, or at night in about 20 fathoms.

From Cape Granatola to Cape St Marco there is a long but slender bay, called the Gulf of Tre Fontane, 20 miles deep. It is of easy access, but has no good shelter except for small vessels. In it, near to Port Paolo, are the solitary extensive ruins of *Selinus* or *Selinuntum*, appearing, at no great distance, like a large city; and 4 miles east of them the Belici (*Hypsa*), which rises near Corleone, and has a course of upwards of 30 miles, falls into the sea.

From St Marco to Cape Bianco a similar bay extends about 14 miles, in which there is good anchorage; but it is only safe in the summer months near the town of Sciacca, the *Thermæ Selinuntiæ* of antiquity; a poor but large place. The baths are supplied by two springs; one of which is sulphureous and hot, being about 126° of Fahr.; the other cool, being about 60°, and impregnated with the saline qualities of the rock from which it springs. The steam-baths of Dædalus are situated on an insulated rock, and have been in use upwards of three thousand years.

Close to the north of Cape Bianco the Platani (*Halycus*), next to the Salso, the largest river in Sicily, empties itself. On its left bank are the ruins of *Heracleia Minoa*, and 8 miles beyond it is the town of Siculiana, pleasantly situated, but in an unhealthy climate. The chief trade consists in the exportation of sulphur, of which there are some extensive mines in the neighbourhood. The city of Girgenti (*Agrigentum*), 10 miles farther east, stands on a hill at nearly 1200 feet above the level of the sea, and is so elevated that almost every house in it can be seen at once. It has a cathedral, a large and heavy structure of the thirteenth century; but it is irregularly built, dirty, and poor. *Agrigentum* was renowned for its power and commercial enterprise, and is said to have once contained 200,000 inhabitants. Most of the space which it occupied is now a continued range of orchards and gardens, and of groves of almond and olive trees. The vestiges of the city have been amply described by Admiral Smyth in his able and accurate account of the island. The port is formed by a mole, having on it a lighthouse; and outside of it there is good anchorage. At this port, also, large quantities of sulphur are shipped.

About 5 miles from Point Bianco, and 2 miles from the shore, is Palma, which overlooks one of the richest and best cultivated valleys in Sicily, and near to it many cattle are reared. About 10 miles from Palma, is Alicata (*Phintia*), at the mouth of the River Salso (*Himera*), the largest river of Sicily, which rises in the Madonia mountains, only 15 miles from the N. coast, and traverses most of the island in its course of more than 50 miles south. At the entrance there is a bar, on which the surf beats so heavily with southerly winds, that boats can only enter it by a narrow passage, which is always difficult, and sometimes dangerous.

At the distance of 14 miles from Alicata, along an open beach, is Terra Nova (*Gela*), where Æschylus ended his days. About a mile from the town there is good anchorage in from 7 to 10 fathoms water, but it is much exposed when the wind blows from the south-west. The town is situated on a table-land, considerably elevated; and it has a fine palace, but few other edifices worthy of notice. The country around abounds in corn.

The whole coast to Cape Scalambra is within a reef of rocks, always an object of peculiar dread to the ancients, and, notwithstanding all the improvements made in navigation, the cause of the loss of many ships. It is not safe to approach nearer the shore than a depth of water of 14 fathoms, nor, with a westerly wind, quite so near as that depth. The eastern side of Cape Scalambra has a small port for vessels of an easy draught of water. From Cape Scalambra the distance to Point Spina is 8 miles; at the latter place the coast is foul and rocky; but at three leagues farther is the town of Pozzallo, which is the chief shipping place for the produce of the district. The next point is Cape Passaro, the southernmost land of Sicily, being in north lat. 36. 41. 30. It is formed of bold projecting rocks, and immediately off it is the small island of Correnti. Near to it the water of the limpid stream of Busaidone irrigates the land of Spaccaforno, a town 3 miles from the shore. It trades with Malta, to which it exports grain, flax, carrubas, acorns, and live cattle.

The west shore, which extends from Cape St Vito to Cape Granatola, will require but a short description. Proceeding from Cape St Vito southwards, we come to Cape Emilia, opposite to which is the dangerous shoal of that name, on which there are only 2 fathoms of water, whilst everywhere around it there are from 6 to 10 fathoms. Immediately to the south-east of it rises Mount San Giuliano (*Eryx*), on whose summit, on the place now occupied by a prison, stood the famous temple of Venus, who derived from it the surname of *Erycina*. Only a few vestiges of it now remain, built up in the walls of the prison; but in the town of San Giuliano near it, which has about 7000 inhabitants, there are in the houses several fine granite columns, which undoubtedly belonged to the temple.

At the distance of 4 miles west of San Giuliano is the city of Trapani (*Drepanum*), which may be approached with safety by vessels of from 200 to 300 tons; though, as the ground is much broken, and there are many counter-currents, great care is required on the part of the pilot. Trapani is surrounded by a wall with bastions and ravelins, and among its inhabitants are some of the best artists, artificers, and sailors of the island. It is a place of considerable enterprise and industry; well built, and with a fine cathedral and senatorial palace. From Trapani southward to Capes Boëo and Marsala, a distance of 10 miles, the coast is low, irregular, and varied by numerous islets resting upon a base of shoal and rocky ground which in some parts extends 2 miles from the shore. The country on the main island is laid out in extensive saltworks, by the construction of causeways about a foot and a half high, enclosing square places which communicate by dams with each other. The salt is heaped up in a pyramidal form, at a distance resembling tents, and when quite dry, is exported chiefly to Marseilles.

Cape Boëo, the westernmost point of the island, and that nearest to Africa, from which it is only 80 miles distant, is a low rocky headland, above which, in a healthy situation, stands the city of Marsala, the ancient *Lilybæum*, founded by the Carthaginians in B.C. 397. Lilybæum had a good and much-frequented port, though neither spacious nor deep, but it was blocked up with sunken stones by order of the Emperor Charles V., to protect the place from the attacks

of the Algerine corsairs. The Saracens, during their domination in Sicily, attached so much importance to it, that they called it Massa Alla—the port of God—from whence the modern name of the city arose. Marsala is tolerably well-built and surrounded by a wall, and exports wine, fruits, and barilla. Near to it there is a large establishment for shipping its wine to England, where it is well known by the name of "Marsala." The ground on the beach is all shoal and foul, and large ships must anchor at nearly 2 miles from the mole, which has been constructed near the English wine-stores of the two houses of Bingham and Cumming Wood.

Off the coast, between Trapani and Marsala, lies a group of three small islands (*Ægates*), of which the westernmost and most distant, Maretimo (*Hiera*), is 22 miles from the coast of Sicily. Favignana (*Ægusa*), the largest and southernmost, and Levazzo (*Phorbantia*), the smallest and northernmost, are at about a distance of 6 and 8 miles off. On Maretimo and Favignana there are the worst dungeons in the kingdom for political and common criminals.

About 10 miles S.E. of Cape Boëo is Cape Feto, and 3 miles further S. the city of Mazzara, situated at the mouth of a small river of the same name, 6 miles north of Cape Granatola. It retains its ancient name (*Mazara*), and though the streets are narrow and dirty, its domes, rising above the houses, give it a respectable appearance from the sea. It is surrounded by a Saracenic wall, and has some trade in the exportation of grain, pulse, wine, fruit, barilla, madder-root, oil, and soap. Its little haven is formed by the entrance of the river, and is convenient for small craft, but larger vessels are obliged to lie at a very exposed anchorage without, in from 8 to 12 fathoms water, where the holding ground is a stiff clay.

The tides, or rather the currents, arising from the constant evaporation and the action of the winds, observe no regularity, rising a foot or two, according to the weather, and the peculiarities of locality and depth. Thus, the north-west winds, raking the shores, produce a strong set to the south-east, whilst the south-west wind, which is very sensibly felt during the vernal equinox, causes strong counter-currents; and at length, on a change of wind to the opposite quarter, the whole body of water rushes with great velocity to the westward. In settled weather, the currents between Sicily and the African shore run to the eastward at the rate of from half a mile to a mile an hour. In the channel of Malta, the current at south-east has been found so strong, that ships have found it difficult to beat up to Maritimo; whilst others, driven to leeward of Malta, have been obliged to carry a press of sail in order not to lose way, until a change of wind enabled them to make the island again.

An atmospheric phenomenon which deserves notice occurs principally on the southern coast of Sicily, but exhibits its greatest force in the neighbourhood of Mazzara. It commonly bears the name of *Marobia*, and is thus described by Admiral Smyth:—"Its approach is announced by a stillness in the atmosphere and a lurid sky, when suddenly the water rises nearly two feet above its usual level, and rushes into the creeks with amazing rapidity, but in a few minutes recedes again with equal velocity, disturbing the mud, tearing up the sea-weed, and occasioning a noisome effluvia. During its continuance the fish float quite helpless on the turbid surface, and are easily taken. These rapid changes generally continue from thirty minutes to two hours, and are succeeded by a breeze from the southward, which quickly increases to heavy gusts."

To the north of Sicily, between E. Long. 14. 13. and 15. 15., and N. Lat. 38. 20. and 38. 50., is the volcanic group of the Lipari Islands (*Insulæ Æoliæ*), consisting of Lipari (*Lipara*), the largest, and the seat of the local authorities; Vulcano (*Hiera*), the nearest to the Sicilian coast, from which it is only 12 miles off; Stromboli (*Strongylæ*), the northernmost; Salina (*Didyme*), next to Lipari in size; Felicudi (*Phœnicusa*); Alicudi (*Ericusa*), the westernmost of the group; Panaria (*Enonymus*), and some smaller islets. Vulcano and Stromboli are small but constantly active volcanoes. On Salina there are two conical mountains, which attain an elevation of 3500 feet above the level of the sea. More particulars about them will be found under the head LIPARI.

Ustica (*Ostœdes et Ustica*), and Pantellaria (*Cossura*), are two small islands of volcanic origin; the former, about 10 miles in circumference, is situated 60 miles west of Alicudi, and 40 miles north of the Cape di Gallo, and is a sort of beacon to ships going to Palermo from Naples. Pantellaria, west of Cape Granatola, and nearly half-way between Sicily and the African coast, from which it is only 38 miles, is 30 miles in circumference, and has nearly 6000 inhabitants.

Politically annexed to Sicily, but geographically belonging to Africa, are the small islands of Lampedusa (*Lopadussa*), Lalenusa, and Scola, situated almost midway between Malta and the African coast.

From the vast extent of sea-coast appertaining to the two divisions of the kingdom, the fishery naturally is, next to agriculture, the chief source of occupation to the inhabitants. Its principal branches are those for the tunny, or *scómber-thynnus*, the swordfish, the anchovy, and the sprat. The tunny was, according to Oppian, in the highest estimation with the Greeks, the Carthaginians, and the Romans, who made from it the sauce called *garum*. Shoals of them enter the Mediterranean in the spring, with an extended base for the tides to act upon, as they swim broad and deep in a conical form. In the progress of the shoal to the eastward it inclines over towards the European coasts, and is caught in great abundance in May, June, and July. The average length of the tunny is from 4 to 8 feet, and the girth from 2 to 5; yet there are many of still greater size, and the females are always the largest.

The manner of taking them is similar to that which was practised by the ancients. Large nets are spread out in the shape of a parallelogram, about 1500 feet in length, 300 in width, and from 40 to 100 in depth, divided into four quadrilateral rooms, having channels of communication with each other. These nets are moved east and west at about a mile distant from the shore, across the known route of the fish, with each of the spaces at right angles, and secured vertically by a number of anchors and stones at the bottom, whilst the upper edge of the net is floated by large logs of the cork-tree. The whole is connected with the shore by a stout single net of large meshes, called the wall, that arrests the progress of the tunny, and induces them to enter the outer room, which is thereupon raised a little and closed by the boatmen on the look-out. The fish, alarmed, and seeking to escape, swim from side to side, and thus enter the next room, when their retreat is again prevented, and thus finally they enter the fatal part, called *corpo*, where the meshes are smaller and stronger, and made of rope of superior quality. When this chamber is filled, large flat-floored boats, assisted by smaller ones, close round, and, weighing the net, secure the prey with harpoons struck into the head to prevent the fish from floundering. Although this fish has rather a coarse appearance, the flesh is agreeable to the taste, and very nutritious.

The sword-fish passes by the shores of Sicily, in its route to the Black Sea, about the time of the vernal equinox, and is often taken in the tunny nets; but in the Straits of Messina there is a particular fishery for them. It is taken by the harpoon, in a manner similar to that practised in the whale-fishery. When the fish is struck it immediately dives, and the long coil of rope fastened to the harpoon is suffered to run out till the animal becomes faint;

but it is sometimes so vigorous as to oblige the fishermen to cut it adrift, lest it should draw the boat under water. The length of this fish is from 7 to 13 feet, exclusive of a sword projecting from the snout, about 3 feet long and 3 or 4 inches broad. The flesh is esteemed delicate food, and, when broiled in slices, resembles veal.

The anchovy and the sprat are taken in shallow water in the months of March, April, and May, by means of nets 10 or 12 feet wide, and very long. The curing of them occupies about a month. The fish are first thrown into brine, to give the salters time to nip off their heads with the finger and thumb, and pack them with alternate layers of salt, in barrels about 200 pounds each. When the cask is filled, a round board is placed over the whole, and loaded with stones, by which the contents are sufficiently compressed in a few days to allow of the casks being properly coopered up for exportation.

Several parts of the coast swarm with barbel, whiting, red mullet, sole, white smelt, mackerel, seabasse, sturgeon, and gray mullets, the roes of which are converted into a sauce called *botarga*. A variety of testaceous and crustaceous fish, amongst which prawns of gigantic size are also taken along the shore. Coral yields considerable profit to the seamen of Trapani and Torre del Greco, who fish it on the African coast.

The geology and the mineral wealth of the country are scarcely known. In the Abruzzi some mines of anthracite and petrolium are worked on a very small scale. The largest iron-works are at La Serra, Mongiana, and Stilo, in Calabria Ultra I.; they are fed by the ore found in the surrounding mountains of the Aspromonte. There are mines of rock-salt, which are but slightly worked, that substance being instead largely collected on the sea-shore, especially of Apulia, where it is prepared by the operation of the sun alone both for domestic consumption and for exportation. Some alum is also collected; and in many parts quarries of marbles of various descriptions are worked, of which, however, none are exported. The mineral production of most importance, as an article of foreign trade, is sulphur, which is only found in large quantities in Sicily. The sulphur districts are principally in the central and south-western part of the island, and are calculated to extend over an area of about 2400 square miles. In 1858 there were more than 200 mines, capable of yielding upwards of 160,000 tons of mineral per year. From January 1858 to November 1859, the quantity exported amounted to 306,967 tons.

The climate is in general healthy, except in those districts where stagnant water produces malaria; but it varies considerably in the different parts of the kingdom. Whilst on the elevated mountain districts of the Abruzzi and Molise, especially near the Monte Corno, the Maiella, and the Monte Greco, there is a real Alpine climate, the snow lies several months on the ground, the thermometer falls below zero, and none of the plants of temperate latitude thrive; along the sea-coasts, on the contrary, the winters are mild, and the thermometer seldom or never falls to the freezing point. The contrast is peculiarly striking in Calabria, where, on the table-land of the Sila, the winters are intensely cold, the snow remains for a considerable part of the year on the higher peaks, and light frosts are not uncommon even in June and August; and yet, at a distance of a few miles on the sea-shore, orange and lemon trees attain a great size, the palm-tree, the sugar-cane, and other plants of tropical latitudes grow luxuriantly, and the cactus and American aloe are used for hedges. In summer the heat of the sun, tempered by the breezes from the sea, is never oppressive, except when the south wind, called *scirocco*, prevails. The scirocco is not actually unhealthy, but produces a general feeling of lassitude and depression, which however disappear without leaving any lasting effects as soon as the wind shifts to any other point of the compass. The quantity of rain which falls annually on the Tyrrhenian coast is about 29 inches, or one-third more than in Paris, yet the number of rainy days is greatly less than in that capital. On the eastern shores, both of Naples and of Sicily, the quantity of rain that falls, as well as the rainy days, are much less than on the western side. Sicily of course is, upon the whole, much warmer than the continental provinces; but even at Girgenti, or Syracuse, the glass seldom, and then only for a short time, rises above 90° in summer.

The Two Sicilies are essentially an agricultural country, the cultivation of the soil being the chief occupation of the people, and almost their only means of subsistence. Their agriculture may be classified under four different systems—the Mountain system, the Campanian system, the Apulian system, and the Sicilian system.

In the Mountain system, which applies to the cultivated districts of the northern and central provinces of the kingdom in general, except the higher range of the mountain-chain, the size of farms varies greatly from 6 to 200 English acres, and the rotation, generally, is as follows:—First year, fallow or potatoes, or a summer crop of maize, beans, or lupins, &c.; second year, wheat; third year, wheat; fourth year, oats or barley. In elevated situations the third year is a crop of barley, followed by two years of rest, during which sheep are driven to graze down the herbage. The ground is prepared in August, September, and October, and wheat, barley, or oats are sown in November.

The Campanian system prevails in the tract of country which extends from Gaeta to Salerno, and includes the rich Campanian plain. Farms are generally of a small size, from 2 to 50 acres, and are let for a period of from four to twelve years. The richness of the soil, and the abundance of manure, enable farmers to have no fallow in the rotation of crops, and to keep the ground in a constant state of high cultivation. A rotation in frequent use is—First year, hemp; second year, wheat; third year, spring wheat; fourth year, wheat. But the practice that more generally prevails, and which is the characteristic feature of the Campanian system, is to have the ground planted with rows of elms or poplars, and vines trained from tree to tree. Grain and other crops are raised under the shade of these trees—a practice which, far from being a proof of bad farming, in that climate is found to give crops of better quality, and though not so abundant as they might be if there were no trees, yet deficiency in quantity is more than made up by the variety of produce raised on the same soil. In the farms where this cultivation is adopted, artificial grasses or lupins are raised in October, to provide food for the cattle in winter. Early in the spring the ground is ploughed, and maize is sown in furrows, with beans, potatoes, melons, &c., in the spaces between the furrows; and when these summer crops are gathered in, the ground is ploughed again, and wheat sown. Sometimes, instead of elm or poplar trees with vines, olive or mulberry trees are planted in rows of from 30 to 40 feet apart; and green crops, hemp, maize, or wheat are also grown under them. Several farms are entirely laid out in orchards containing a great variety of fruit, such as apples, pears, apricots, peaches, figs, plums, almonds, walnuts, &c., with stone-pines towering over them all. Madder-root has of late years been introduced, and cultivated to a considerable extent in the plain on the S.E. slope of Vesuvius.

The Apulian system is peculiar to the great plain already described as extending from the Fortore to the Ofanto rivers, and from the foot of the Apennines to the shores of the Adriatic, and known by the local appellation of *Tavoliere di Puglia*. Nearly the whole of this vast treeless flat, parched up in summer, and clothed with luxuriant herbage in winter, belongs to the crown, and is chiefly laid out in pasturage. From the earliest times, the Marsican and Sam-

nite shepherds were in the habit of leading their flocks from their high mountains to this plain for the winter pasturage. This periodical migration greatly increased when the second Punic war had depopulated the few cities which existed on the plain; and the Romans, when masters of the country, imposed a *vectigal*, or fixed tribute, on the right of grazing upon it—a tax more or less enforced during the middle ages. Till the fifteenth century the winter migration of the flocks was voluntary; but, in 1442, Alfonso I. of Aragon made it compulsory, and established the system of the Tavoliere, which, with some alterations, lasts to the present day. Alfonso appropriated to the crown all commons and waste lands to which no good title could be shown, and divided them into *Locazioni*. To give greater accommodation to the flocks, which his laws compelled to resort to Apulia, he bought from several feudal barons and convents the right of grazing on their adjoining lands, which he designated by the name of *Ristori*. To convey the flocks to and from the plain, several great roads, called *Tratturi delle Pecore*, were traced, with some adjacent tracts of land, called *Riposi laterali*, on which the flocks were allowed to rest and graze for twenty-four hours on their march. Two general *Riposi*, or resting-places, were also provided at two extremities of the plain, on which the sheep might stop till the proprietors declared the number of their respective flocks, and the crown officers verified them, and apportioned to them their pastures. The farmers were compelled to sell the produce of their stock at Foggia, where the tax was paid into an office called the *Dagana di Foggia*, and they were not allowed to leave the Tavoliere without a passport, which of course was not granted until the taxes were paid.

Under the Spanish viceroys the system became so odious and oppressive that Charles III., on his gaining possession of the kingdom, made the Tavoliere the subject of an official inquiry; but no great changes were effected till 1806. In that year, by a law of Joseph Buonaparte, farms held under the crown were declared freeholds of those who were in possession of them; and the occupants of lands assigned to them for grazing were declared owners of such lands, on payment to the crown of a certain rent, which was fixed according to the number of their flocks, and was redeemable at will. After the restoration of the Bourbons, however, Ferdinand I., with the exception of compulsory migration, which is at an end, re-established the old system, by taking the land from those who had been in full possession of it for ten years, by making rents and charges irredeemable, and by forbidding the ploughing up or planting of any part of the land without an express licence from the crown. The collection of the taxes, which are calculated to bring about L.70,000 a year, is confided to a magistrate called the *Direttore del Tavoliere*, who is also the governor of the province of Capitanata.

The Sicilian system prevails in Sicily, and the continental provinces of Bari, Otranto, and Calabria. The general rotation is—First year, fallow or summer crop; second year, hard wheat (*grano rosso*); third year, a lighter kind of wheat (*maiolica*); fourth year, oats. Cotton is sometimes planted the fourth year; and of late years rice has been introduced in the marshy districts. But olive, almond, fig, and orange trees, and vines, form a more important branch of the cultivation. More than one-half of Terra di Bari and Terra d'Otranto, and great tracts of the western shores of Calabria, are covered with olive-trees, which are propagated by slips, by shoots, and chiefly by grafting the wild olive either *in situ*, or, if transplanted, a couple of years after it has taken root. It takes at least twenty years before an olive plantation begins to bear a satisfactory return. The flowering of the olive-trees begins towards the end of May, but the fruit is not ripe till November. Except in very few favourite spots, the olive-tree does not give a yearly return. A plantation is considered very good if it brings a tolerable quantity of fruit every other year; generally a good return is only every third year. The vineyards are very extensive, but the vines are not trained in festoons, as in the provinces of Naples, Terra di Lavoro, &c., but low, as they are in the south of France.

The area of the continental provinces is supposed to contain about 20,220,516 English acres, of which only 11,430,972 acres are reduced under cultivation; the remaining 8,789,544 acres being occupied by waste land, lakes, rivers, buildings, roads, &c. The peasants who cultivate the land, though receiving on the whole small wages, are not badly off, except in Capitanata, in Basilicata, and in some other mountain districts. In many districts they are commonly *metayers*, dividing equally with the lord or the farmer the annual produce; but where the soil is peculiarly fertile, the peasant has but one-third of the harvest for his share. Most of the soil was formerly owned by the crown, the king, the higher aristocracy, and the religious houses; but a great change has taken place since most of the mortmain lands were seized by the state on the suppression of convents and nunneries in 1806, and afterwards sold. The abolition at the same time of entails and the new laws of succession increased the number of landowners, by the breaking up of large estates; the tendency at present seems rather to be towards too great a subdivision of property, particularly near the large towns.

The principal productions of the country include all those of the temperate, and several of the torrid zone. In most years more corn is grown than is required for the consumption of the inhabitants—the full year's average of the crop being estimated at about 14,000,000 English quarters. It might, however, be tenfold increased by bringing into cultivation some of the rich land of the plains which are now a waste, if the constant practice of the government of prohibiting exportation of corn whenever its price is not low, did not effectually check that branch of agricultural industry. Oil is, next to corn, the most important agricultural production. It is the substitute for the butter made in northern Italy, and enters largely into all the edible preparations of the inhabitants. It is generally used in lamps, to supply the place of candles, and a large quantity of it is converted into soap. The best oil for culinary purposes is made out of the olives before they turn black; that of Vico and Massa near Naples, of Venafro in Campania, of Trani and Monopoli in Apulia, and of several other places in Calabria and Sicily, is in high repute. The oil-mills are the same as those used in ancient times, and are generally at work from November to March, and in years of great returns even till May. The oil, as it is prepared, is sent to different places of depôt along the coast, where it is collected for exportation, and is deposited in large subterranean tanks excavated in the limestone rock, where it clears, and keeps, if necessary, for many years. The quantity of oil deposited by a proprietor is guaranteed by a ticket which is given to him, and upon which he may borrow money, and eventually effect the sale of the article.

The vine is extensively cultivated, but so little care is bestowed in the selection of the varieties in planting it, and so little skill is exercised in the preparation and treatment of the wines, that a large quantity of the produce is only fit to be converted into brandy. Under different circumstances the Two Sicilies might supply the whole market of Europe with wine, as vineyards might be increased to any extent, and capital and skill are all that are required to produce excellent wines. An illustration of this is given by two English houses established at Marsala, in Sicily, that prepare wine of tolerable quality and flavour, and of durable strength, which, under the name of Marsala, has found its way in considerable quantity into the English market. Several local wines, however, in spite of the unskilful way in which they are prepared, are excellent, and strong

enough to bear a sea-passage, and only require to be known to be appreciated. Such are the Pellagrello of Piedimonte, the red and white Gerace, the red Taranto, the Muscat of Trani, the Aleatico of Bari, the red Arpino, the Capo di Lecce, the Monte di Procida, the Syracuse, the red Cirò, the white Torre del Greco, the red Somma, &c. &c.

Both on the continent and in Sicily much silk is produced, but little beyond what is required for domestic consumption. In late years the cultivation of the mulberry-tree has increased, but the same skill and diligence is not applied to it as in Lombardy and Piedmont. Figs are extensively cultivated, and their fruit, dried in the sun in September, and in some places, baked afterwards in an oven, is an article of winter food to the lower classes. Another article of food are chestnuts, which are supplied by the sweet chestnut-forests that clothe extensive tracts of the mountain districts. Almonds form an important item of the productions of the province of Bari. The liquorice-juice brought to the English and French markets is extracted from the liquorice-root that grows wild in many districts of Calabria. The average annual growth of cotton wool is about 80,000 bags, a quantity far below the home consumption. Flax and hemp, wool, cheese, tobacco, saffron, manna, raisins and currants, oranges, lemons, capers, caroubas, sumac, madder-root, castor-oil, beans, rice, honey, &c., are the other principal agricultural productions of the kingdom.

The live stock is supposed to be nearly as follows:—sheep, 4,700,000; goats, 720,000; oxen and cows, 360,000; buffaloes, 50,000; horses, 110,000; mules and asses, 890,000; pigs, 2,400,000. About two-thirds of the whole number of sheep are migratory, being kept, as already stated, in the mountains in summer, and in the plain of the Tavoliere in winter. They are shorn twice a year, totally in the spring, and only partially in the summer. The wool varies in quality, but is in general good, and most of it is exported. But the chief return to the farmer is from a kind of ordinary cheese made from the milk of the ewes. Cows' milk is made into butter only near Naples, Palermo, and a few other large towns; generally it is converted into a kind of cheese called *Caciocavallo* and *Provole.* The oxen are commonly used to plough the land, and to draw waggons or carts. The horned cattle in the Terra di Lavoro, in Terra d'Otranto, and the S.W. of Sicily, are white, very large and splendid-looking animals. Buffaloes are used as beasts of draught, and their milk is made into a kind of very ordinary cheese. Mules abound in the provinces of Otranto, Abruzzi, Principato Ultra, and Sicily; they are used for ploughing, for drawing carts, but chiefly for the internal traffic over paths across mountains; in some of the provinces they are even used in the carriages of the upper classes and the clergy. Some of the breeds of horses are fine, especially those reared in the Tavoliere, in the plain of Pæstum, and in Calabria; but they have much fallen off in consequence of a heavy tax laid on their exportation in the last century, and the present prohibition of importing foreign horses. The swine are generally black, though the white are not uncommon; at Sorrento, and in other places further south, they are devoid of bristles.

The manufactures of the kingdom are for the most part of the domestic kind. The females spin the flax, hemp, wool, or cotton, and make coarse cloths, with which the condition of the great body of the lower classes compels them to be satisfied. Within the last forty years, however, considerable progress has been made, and large manufactories of various kinds have been established in different parts of the country. At San Leucio, at Catanzaro, at Reggio, at Naples, and at Catania, silk goods are made, which are in great demand, and Sorrento is celebrated for its silk socks. Arpino, Sora, and Isola have paper-mills and manufactories of woollen cloths, made of Apulian wool. Near Salerno, at Sarno, at Scafati, &c., there are cotton-mills, linen and calicut manufactories, &c. Carpets are made at Ischia, and in the neighbourhood of Naples. Amalfi, Gragnano, and Torre Annunziata are celebrated for their macaroni. The best quality of it is made from the hard wheat grown on the Tavoliere (the *grano rosso* of Barletta), which is reduced to flour by the usual process of grinding. At Atripalda there are iron-foundries, fulling and paper mills. Leather, hardware, glass, earthenware, porcelain, ropes and cordage, hats, gloves, artificial flowers, &c., though of indifferent workmanship, are also made in several towns.

Many of the continental provinces have *Monti Frumentarii*, which, in aid of agriculture, lend wheat to farmers at the sowing time on a small return in kind after the harvest. In most large towns there is also a *Monte di Pietà*, or government pawn-bank, which lends small sums at 5 per cent. to the poor; but there are no saving banks, as their operations would interfere with the Lottery revenue. The only saving bank in the kingdom was opened at Naples in 1855, and in 1857 it had L.1525 of deposits in 479 accounts. It receives sums from 4d. upwards, and when they reach 3s. 4d. it allows an interest of 3 per cent.

Accounts are kept in ducats of 10 *carlini* or 100 *grani* each; but the currency is in *piastre* of 12 carlini. The carlino, at the exchange of 600 grani to L.1, is equal to 4d. The *palmo*, equal to 10·35 inches, is the unit of the measures of length. 10 palmi form the new *canna*, and 8 the old canna, still in common use. The mile is the geographical mile of 60 to a degree. The measures of capacity vary almost in every province, the standard measures of late years prescribed by government not being yet in general use.

No country in Europe has so little foreign trade, in proportion to its extent and population, as the Two Sicilies; but the absence of any official statistical returns renders it impossible to give a correct account of its nature and amount.

The mercantile navy of the continental possessions, in 1825, consisted of 5008 ships, and 107,938 tons; in 1855 it had increased to 8988 ships, and 212,965 tons. The chief emporium of the trade is Naples, to which the greater portion of the spare products are brought by small coasting-vessels, and whence also are dispensed what foreign commodities are required. The other principal places where there is some foreign trade are—Castellammare, Reggio, Taranto, Gallipoli, Bari, Molfetta, Barletta, Manfredonia, and Termoli. Sicily in 1856 had 2300 ships, and 123,775 tons, of which the greatest portion belonged to Messina and Palermo. Next in importance are Catania, Trapani, Marsala, and Castellammare.

The imports of the continental provinces, in 1856, were estimated at about L.2,744,760; and the exports at L.3,353,513, showing a surplus of 808,753 in favour of the latter. The principal articles of importation were—cotton yarn and cotton wool, sugar, woollen manufactures, tobacco, coffee; and the chief articles exported—oil, corn, wheat, silk, madder-root, wool, almonds, and fresh and dried fruits. With respect to the various countries, and in the order of their respective importance, the largest imports were—from England, France, America, Holland, Sardinia, &c. And the exports to France, England, Austria, Russia, Holland, Sardinia, &c.

We have more reliable information with regard to the existing trade between this country and the Two Sicilies, the nature and extent of which will be shown by the subjoined abstract tables, from the official statistical returns of the trade and navigation of the United Kingdom, presented to both Houses of Parliament by command of her Majesty. It will be seen that the imports from the Two Sicilies, which in 1854 were of a computed real value of L.1,411,457, in 1858 had risen to L.1,656,523. The increase of the exports thereto is even more remarkable. From L.672,291 in 1854, they had steadily risen in 1858 to L.1,787,300.

Sicilies.

The most important articles of importation, in 1858, were—oil, L.601,651; brimstone, L.452,202; sumac, L.121,179; madder-root, L.103,386; oranges and lemons, L.72,044; wine, L.41,585; and the principal articles of exportation—cotton yarn, L.489,686; ditto, by the yard, L.352,068; ditto, at value, L.13,601; iron, wrought and unwrought, L.228,850; woollens by the yard, by the piece, and at value, L.165,070; hides, not tanned, L.74,791; indigo, L.73,474; coals, cinders, and culm, L.52,420; linen by the yard, L.38,220; linen yarn, L.22,949; steam-engines and machinery, L.41,088.

Imports from the Two Sicilies into the United Kingdom.

The internal trade of the country has increased considerably since the opening of many excellent carriage-roads. In the beginning of this century there were only the post-road from Naples to Terracina, the roads from Naples to the royal hunting-parks of Venafro, Bovino, and Eboli, and the road from Palermo to Bagheria. Several roads were projected and begun under the French, chiefly with a view to military operations; but most of the great roads now open have been constructed since 1815.

Five high post-roads start from Naples for Terracina, the Abruzzi, Molise, Puglia, and Calabria, reaching, with their main trunk or their branches, the capitals of all the fifteen continental provinces, and some of the capitals of the districts. The road of the Abruzzi branches at Popoli into two main lines, both of which enter the Papal territory; one inland, by Civitaducale and Rieti, the other along the Adriatic by Porto-di-Fermo and Ancona. Another inland road, by San Germano, enters the Papal States at Ceprano. All these roads are constructed with remarkable engineering skill, and are in excellent condition. They are kept up at the expense of the state. The provincial roads which start from the capital of the province to the chief town of the district, are open and kept up at the expense of the provincial funds, and the communal roads at the expense of the different communes interested in them. There are no tolls of any kind. There are many provincial roads projected, but not even begun, and the communal roads open are very few, except in the province of Terra-di-Bari, where internal roads open communications among the principal towns. As an illustration of the great want of roads still existing, it may be mentioned that there is no direct road connecting Brindisi to Taranto, the two principal ports on the Adriatic and the Ionian; none from Taranto along the shore of the Ionian Sea to Castrovillari and Cosenza; none from the eastern to the western shores of the province of Basilicata; none from Foggia to Melfi, &c. &c. In Sicily, the only public roads open to traffic are—from Palermo to Messina, with a branch to Catania; to Castrogiovanni; to Marsala by Alcamo; to Castellammare, along the coast; to Termini and Cefalù; to Girgenti by Caltanissetta; and from Messina, along the eastern base of Ætna, to Catania and Syracuse, with a continuation from the latter place inland to Noto. The only railways open are, from Naples—a line of 26 miles to Cava, with a branch of 4 miles to Castellammare; a line of 22 miles to Caserta and Capua, with a branch of 8 miles to Nola and Sarno.

Till January 1848, the government of the Two Sicilies was, in theory as well as in practice, an unmixed absolute monarchy; but on the 10th of February of that year, a constitutional charter was freely granted by the late king Ferdinand II., which restrained the previously unlimited

 powers of the sovereign. The principal provisions of the charter are—

The Two Sicilies will be a *constitutional hereditary monarchy*, in which the executive power belongs exclusively to the king, and the legislative power is collectively exercised by the king, and a Parliament, composed of two houses, an upper and a lower one.

The king has the command of the army, declares war, and makes peace; he also negotiates treaties of commerce and alliance, subject, however, to the approval of parliament previous to their ratification. All his acts must be countersigned by a responsible minister.

The Upper House, or *Camera de' Pari*, is composed of an unlimited number of members nominated for life by the king, from among persons at least thirty years old, who either are in possession of a net income of L.500 a year, or belong to one of the ten categories enumerated by the charter. The princes of the royal family are peers by right at the age of twenty-five, but have no vote till they are thirty years old. The upper house is the high court to try any member of parliament for high treason.

The Lower House, or *Camera de' Deputati*, is composed of deputies returned by the electoral districts into which the kingdom is divided; there is a deputy returned for every forty thousand inhabitants. Both the deputies and their electors must be at least twenty-five years old. They must have from landed property, from mortgages, or in the public funds, a net yearly income, fixed by the electoral law of May 24, 1848, at two pounds for the electors, and at twenty pounds for the deputies; or, in the absence of such an income, they must be members of one of the royal academies, professors in one of the universities or public colleges, &c. The duration of the lower house, unless dissolved sooner, is five years.

Parliament is to meet every year, and in case of a dissolution of the lower house, a new house must be summoned within three months. Neither peers nor deputies receive any salary or indemnity. The sittings of the chambers are public; no sitting is valid unless an absolute majority of their members are present. Each of the three powers of the state has a right of introducing bills, but all money bills must first be introduced in the Lower House. No tax can be imposed or levied without its having previously been assented to by the houses and sanctioned by the king.

No other religion but the Roman Catholic is to be allowed a free exercise. The charter guarantees individual liberty and property; any person imprisoned as a precautionary measure must, within twenty-four hours, be brought before the proper judicial authority, and acquainted with the motives of his imprisonment. No one's domicile can be entered without a warrant of the judicial authority. The press is to be free, but subject to a repressive law for any attacks against religion, morality, public order, the royal family, foreign sovereigns and their families, and the honour and interest of any private person. Judges are irremovable after they have exercised their functions for three years under the constitution. The ministers of the crown are entitled to attend the debates and speak in either house, whenever they deem it expedient; but they have no vote unless they are members. Any member of the lower house who takes office under government vacates his seat, but may be re-elected.

A parliament was summoned, and met under this constitution, in June 1848; it was prorogued in September, and met again in February 1849. On the 13th of the following March, however, a royal decree dissolved the lower house, reserving the naming of a day for proceeding to the new elections, according to the charter. From that time parliament has never been summoned; the constitution, without being formally annulled, or even suspended, has remained in abeyance, and the old despotic practices have been resorted to. The kingdom of the Two Sicilies is thus in the anomalous and perhaps unique position of being in theory a constitutional government, in practice and *de facto* the most thoroughly despotic and arbitrary government in Europe.

The administration, as it was previous to 1848, and as, in defiance of the constitution, it has been ever since March 1849, consists of—a council of state (*Consiglio di Stato*), a council of ministers (*Consiglio de' Ministri*), and a council general for the kingdom (*Consulta Generale del Regno*). The *Consiglio di Stato* has an unlimited number of members, appointed directly by the king, in order to give their opinion, when required, on any subject relating to the internal affairs or foreign relations of the country. Their meetings are presided over by the king, or the heir-apparent, if of age, or the president of the council of ministers. The functions of this council, which has a certain resemblance to our privy council, are merely consultative, and do not in any way bind the king or his ministers to any course of policy.

The *Consiglio de' Ministri*, which answers to our Cabinet, consists of the ministers-secretaries of state, and is presided over by the president of the cabinet. Their resolutions are submitted to the king, in a conference between him and each minister within whose department the respective subject under discussion lies, and cannot be carried out until they have received his royal sanction. In the absence, or non-appointment of a minister, the corresponding director takes his place at the council, and in the conference with the king. There are ten ministries, each of them called *Real Secreteria di Stato*:—Presidency of the Council, Foreign Affairs, Grace and Justice, Ecclesiastical Affairs and Public Instruction, Finances, Public Works, War and Navy, Home, Police, Affairs of Sicily.

The *Consulta Generale del Regno* is divided into a consulta for Naples, with 16 members; and a consulta for Sicily, with 8 members. Each consulta has a president, and meets separately; but on affairs affecting the whole kingdom they meet together under the senior president. They examine and give an opinion on projects of law, or on such other matters as may be referred to them by the king or any of the ministers. The consulta was established in 1822, as a security for the good government of the country; but like all such half or evasive measures, it neither had any legislative influence, nor produced any good results whatever.

The supreme executive power of the king is carried out through two distinct branches—the *Administrative* and the *Judiciary* power. Their different attributions and respective limits were defined by the organic law of 1817. The system is in substance the same as the French; the difference is chiefly in the details.

In the provinces the former power is represented by a governor, called *Intendente*, who is appointed by the king, and has in his hands the civil, military, and financial administration of the province over which he presides. He is assisted by a secretary-general and a council called *Consiglio d'Intendenza*, and has under him sub-governors, called *Sottintendenti*, in each district into which the provinces are divided. The secretary-general, the members of the council, and the sottintendenti, are also appointed by the king. A provincial council, *Consiglio Provinciale*, consisting of members selected by the king out of lists of landed proprietors, submitted to him by the communal councils, assemble once a year to examine the provincial accounts, recommend local improvements, and praise or censure the conduct of the Intendente.

The *Sottintendenti* of the districts carry out the ordinances and instructions of the Intendente, to whom they report on the petitions or grievances of the comuni, and correspond both with the intendente and the home minister. A district council (*Consiglio Distrettuale*), composed as the pro-

vincial council, meets once a year in order to examine and report to the provincial council on all matters of local interest.

The *Comuni*, into which each district is divided, are arranged in three classes, with a view to their administration. Towns which have at least 6000 inhabitants, or a revenue of L.833 per annum, or are the provincial capital, or the seat of the law-courts, rank in the first class. In the second are those with a population of from 4000 to 6000 souls, or the chief town of the district. In the third, those that have less than 4000 inhabitants. A comune is either a single town, or an aggregate of two or more towns or villages; there are comuni whose population is made up by as many as 24 villages. Each comune is governed by a corporation of very ancient institution, consisting of a *Sindaco*, two assistants called *Eletti*, and a communal council called *Decurionato*. The sindaco superintends the registration of marriages, births, and deaths, which are entered by a communal registrar (*Cancelliere Comunale*), under his orders; has the control of the public establishments, and the management of minor communal affairs; has to provide the commissariat of the troops passing through, and, in the absence of a military commissary, even of those quartered in, the comune; has jurisdiction in some minor causes of communal police, obstructions of roads, occupation of public ground, &c., presides over the decurionato, and corresponds with the Sottintendente and the Intendente. The eletti act as his deputies, and as commissioners of the communal police; the prices and order of the daily market are under the vigilance of the first eletto. The decurionato, which meets once a month, unless specially summoned by the sindaco, forms (subject to the approval of the king in comuni of the first, of the home minister in comuni of the second, and of the Intendente in comuni of the third class) the communal budget, fixes the local rates and taxes for communal purposes, gives the three names out of which the sindaco and the eletti are to be appointed, and submits to the king the names of the proprietors whom they consider eligible for the provincial and district councils. Two-thirds of its members must be present to deliberate.

The sindaco and the eletti are selected by the king or the home minister, according as the comuni belong to the first and second, or to the third class, out of three names (*Terna*) submitted by the decurionato for each of them. If the names are not satisfactory to the authority, the decurionato is directed to submit a new terna. The decurionato is generally composed of three members for every thousand inhabitants, but their number must never in the large cities exceed thirty, and in the small comuni be less than five. Landholders, farmers, artisans, &c., are all eligible, provided they are possessed of a rateable annual income of L.4, or have exercised a liberal profession for 8 years consecutively, in the comuni of the first class; or have an income of L.3 and L.2 respectively, or occupy a farm of a certain size, or exercise a profession or trade in the comuni of the second and the third class. One-third of them at least must be able to write and read. One-fourth of them go out annually, and the lists for the new members (with three names for each member) are formed by the decurionato itself, by ballot, and submitted for selection to the king or the home minister.

Questions relating to commons, communal property, public roads, rivers, lakes, and the sea-shores; questions concerning taxes and excises, or the accounts of their collectors, or of communal and provincial cashiers, &c., all fall within the attribution of the administrative power, and are decided in the first instance by the *Consiglio d'Intendenza* of the province in which the question arises, and in appeal by the Court of Accounts of Naples or that of Palermo, as the case may be. The decision of the latter court, however, cannot be carried into execution unless it is approved by the king in council, who sometimes, before sanctioning or modifying the decision, sends it, on the application of one of the interested parties, to the *Consulta del Regno* for their opinion.

All other matters and questions whatsoever affecting things and persons fall within the attribution of the judiciary power, and are regulated by a Code of Laws (*Codice pel Regno delle Due Sicilie*) promulgated by Ferdinand I. in 1819. It is, in substance, the *Code Napoleon*, which Joseph Buonaparte introduced into the continental part of the kingdom in 1807. Divorce, recognised by the *Code Napoleon*, is expunged from the Neapolitan Code, and marriage is regulated according to the canons of the Council of Trent. The other principal changes are with regard to parental authority, the relations between husband and wife, legitimate succession, and mortgages. With respect to succession, any person who has issue is allowed to dispose by will only of one-half of his whole estate, including both real and personal property; the other half must be equally divided among his, or her, children or grandchildren. With this difference, however, that, if any of the children are alive, the grandchildren succeed *per stirpes*—that is to say, they altogether take and divide among themselves the share which their parent would have been entitled to; but if the children are all dead, and there are surviving only grandchildren, the latter succeed *per capita*—that is, they take an equal share each of their grandfather's inheritance. Natural children are entitled only to two-thirds of what as legitimate children they would have taken; adulterine issue is only entitled to alimony. In case of intestate succession, the whole property is equally divided, according to the same rules and proportions.

The magistrates appointed to administer justice are very numerous, and their respective jurisdiction is defined by the organic law of 1817 (*Legge Organica del Potere Giudiziario*). They are all appointed by the king, badly paid, and, in the present illegal suspension of the constitution, removable at his pleasure. The lowest among them is the *Conciliatore*, who is appointed in each comune from among the inhabitants, including ecclesiastics, receives no salary, and, acting as an umpire, decides without appeal all actions for sums below L.1. In each district there is a judge (*Giudice d'Istruzione*), whose duty it is to collect evidence against criminals, and transmit it to the local courts for prosecution. The districts are divided into Circondarii, of which there are 720 in the kingdom; and in each of them there is a justice of the peace (*Giudice di Circondario*), whose salary, besides some small fees, is from L.4 to L.6 a month, and is paid by the comunes of the Circondario. He decides all civil actions, without appeal, to the amount of L.3, 7s., and subject to appeal to the amount of L.50; all questions arising in a market, or regarding trespasses; all infractions of the revenue laws; and all cases of correctional police, whose punishment does not exceed two years' imprisonment. He also collects and reports upon the evidence of local crimes, and has the general control of the police, where there is no police inspector. In each province there is a civil court (*Tribunale Civile*), and a criminal court (*Gran Corte Criminale*). The civil court, composed of a president, two other judges, a royal procurator, and a chancellor, takes cognizance in first instance, and subject to appeal, of all civil actions exceeding L.50; of questions affecting the state of persons, and of mercantile actions in those provinces that have no commercial tribunal; it also decides, as a court of appeal from the justices of the peace. The criminal court, composed of a president, five judges, a procurator-general, and a chancellor, decides upon graver criminal cases, except military offences, and revises, on appeal, the judgments of the justices of the peace in cases of correctional police. In the provinces of Naples, Capitanata, Calabria Ultra I., Messina, and Palermo, there are commercial courts (*Tribunali di*

Sicilies.

Commercio), having a president and three judges, chosen from the class of merchants, and a royal procurator and a chancellor. They have jurisdiction in commercial cases, without appeal, up to L.4, and subject to appeal beyond that amount. There are six civil courts of appeal (*Gran Corti Civili*) sitting at Naples, Aquila, Trani, Catanzaro, Messina, and Palermo, and consisting of a president, six judges, a procurator-general, and a chancellor. They decide, in the last instance, upon the appeals from the judgments of the civil and commercial courts which fall under their jurisdiction. Above all these courts is a Court of Cassation, called *Corte Suprema di Giustizia*, which for Sicily is held at Palermo, and for the continental provinces at Naples, and consists of a president, two vice-presidents, sixteen judges, a procurator-general, two advocates-general, a chancellor, and two vice-chancellors. It is divided into a civil and a criminal chamber, each with a president, eight judges, an advocate-general, and a chancellor. All judgments from which there is no appeal may be denounced by the interested party to the Supreme Court, on the plea of their being against the law, whose articles alleged to have been infringed must be specified. The court, if there is any violation of the law, quashes the judgment, and sends the contending parties before another judge of circondario, civil or commercial tribunal, criminal court, or civil court of appeal, as the case may be, for a new hearing and a new judgment upon the question. For certain particular criminal cases, eight judges of the ordinary criminal courts are by royal commission invested with special powers, and formed into a special court (*Gran Corte Speciale*), from whose judgment there is neither an appeal to a superior court nor a recourse to the Court of Cassation. There are also a military court (*Alta Corte Militare*), composed of generals appointed by the king, and an admiralty court (*Commissione delle Prede Marittime*).

From this long list it might be inferred that justice has a fair chance in the Two Sicilies, and yet nothing would be farther from the truth. The total absence of a jury, in civil as well as criminal cases, leaves both the finding of the fact and the application of the law in the uncontrolled hands of the judge. But the evil is to be traced to other causes. Ever since the establishment of the present system, the smallness of the salaries, as compared with the profits made at the bar, had contributed to keep away from the bench the best legal minds, whose absence, however, was often made up by common sense and moral principles. Whilst the leading lawyers are likely to make from L.2000 to L.4000 a year, the salary of the President of the Supreme Court, who is the chief-justice of the kingdom, is only L.650 a year! Nothing but death stops the prosperous career of an honest barrister or chamber counsel who has once established a reputation; a judge, even after having through many years toiled his way up to the highest courts, may be, and often is, turned out and left unprovided for whenever individually or collectively he pronounces a judgment distasteful to the government. Of late years the political troubles have increased the evil to an incalculable degree. The criminal courts receive from the head of the police, or from the king's private cabinet, the list of obnoxious persons who are to be condemned for state crimes, irrespective of any evidence. Any resistance to their bidding is visited with immediate destitution. The *Official* Neapolitan newspaper teems with instances of it. Thus, in 1850, the Criminal Court of Cosenza was broken up, and recomposed twice before the government could obtain the conviction of several hundred prisoners against whom there was no evidence; and in the trial of Poerio and his friends, a trial so well known in this country, conviction was secured only by the substitution of several judges. Nor is this all. After the abolition of the constitution of 1821, a circular from the minister of justice inculcated on all the judges in the kingdom that, in the decision of all civil questions, a deference should be shown towards the parties who were loyal to the despotic system. This injunction, against which the moral sense of the country had rebelled and had caused it to be forgotten, was reiterated in 1851. The result of all this has been, that men with any sense of morality, of self-respect, and of independence, keep away from an office which would ruin them in every way. Only a set of poor, unprincipled, ignorant men, who have nothing to lose and all to gain, have consented to be the tools of the government. The scum of the bar has filled the bench. Many an upright man in his old age has been placed in the fearful dilemma of either departing from justice or meeting starvation to himself and his family. Under these circumstances a set of Jeffreys might be found in any country; and the paternal government of Ferdinand II. so well fostered them that Neapolitan justice is become a byeword among nations, and a disgrace to civilised Europe.

Sicilies.

A large army, in part of foreign mercenaries, naturally is required to maintain this outrageous system. On the 1st of January 1859, the military establishment, including the reserve, the marines and the veterans, numbered 2825 officers, 96,805 soldiers, of whom about 14,000 were Swiss mercenaries, and 8843 horses. The effective part of the army consisted of 2509 officers, 80,029 soldiers, and 8543 horses. The national regiments are raised by conscription from 18 to 25; a substitute may be obtained by a payment of L.40 to the government. The period of forced service is eight years in the cavalry, artillery, and gendarme regiments; five years in the line, with three years' liability to be called again in case of emergency. The Swiss regiments were recruited in Switzerland in force of a stipulation passed with some of the Cantons in 1827. When that stipulation expired, the enlistment took place on the Swiss frontiers. In the course of 1859, a spirit of insubordination having appeared among them in consequence of their being deprived of their national flag, many of them were dismissed and sent home; but as many other foreign cut-throats were enlisted to fill their ranks in the regiments, which have received different names. They receive one-third more than the Neapolitans, and have mattrasses, which are not given to the latter.

The navy has of late years been increased and much attended to. It consists of 2 ships of the line of 80 guns each; 5 frigates of from 60 to 40 guns; 2 corvettes of 22 guns; 5 brigs of 18, and two sloops of 14 guns; and a steam squadron composed of 2 frigates of 400 horse-power each, 10 of 300, 4 of 200, and about 20 more of less power. The number of seamen is about 5000, and that of the marines and artillerymen about 7400.

As no regular budget is ever published by the Neapolitan government, the real financial state of the country is in great part a matter of conjecture. The following particulars, however, without laying claim to strict accuracy, are as near an approximation to it as, in the absence of all official returns, it is possible to obtain.

Under the French rule, 1806–15, all the creditors of the state who were not paid by the sale of public domains or monastic property, were entered into a registry called *Gran Libro del Debito Publico*, and allowed an interest of 3 per cent. on what was due to them. Such was the origin of the funded debt of the country, which, when the French left the kingdom in 1815, was only L.4,666,680, paying an annual interest of L.140,000. The restoration of the Bourbons increased this debt by more than L.3,500,000, L.1,000,000 of which were paid for an Austrian army of occupation from 1815 to 1817. In consequence of the political events of 1821, two new loans were contracted amounting to about L.15,000,000, of which L.14,000,000 were required to pay the expenses of an Austrian army

which entered the kingdom and put down the constitution. On the 1st of January 1848, the savings effected by the late king during many years of peace had reduced the public debt, by means of the sinking fund, to L.13,526,836, paying an annual interest of L.674,800; but in the course of that and the following year the government, without the concurrence of parliament, issued L.5.749,334 of fresh stock, bearing interest at 5 per cent., of which L.2,416,000 were for Naples, and L.3,333,334 for Sicily. The whole funded debt of the kingdom in 1859 may be set down at L.16,959,000 for Naples, and L.3,316,000 for Sicily; total, L.20,315,000, bearing an annual interest of L.960,000.

The revenue in 1858 was reckoned about L.5,300,866, the expenditure about L.5,410,680, leaving a deficit of L.109,814, which was met by various schemes. In 1831 the revenue was L.4,441,667, and the expenditure L.4,976,000. In 1847 the former was L.4,657,171, and the latter L.4,604,868, leaving a surplus of L.52,303. The subjoined table will give an idea of the

Chief Items of the Public Revenue and Expenditure in 1858.

REVENUE.

Land-tax	L.1,205,670
Communal, Twentieth	23,560
Customs, excise, tobacco, salt, snow, gunpowder, playing cards, etc.	2,186,560
Stamps and registers	232,450
Lottery	325,447
Game licences	5,220
Post-office	30,226
Mint and coinage	14,800
Public domains, sinking fund, discount bank	206,500
Royal printing office	2,500
Railroads	39,120
Percentage on salaries of civil and military officers	159,000
Passports	1,050
Charitable trusts' property	164,500
Share of Sicily towards the common expenses	674,263
Miscellaneous	30,000
Total	L.5,300,866

EXPENDITURE.

Presidency.	Office expenses	L.5,500	L.14,300
	Private secretaryship of the king	800	
	Royal printing office	4,500	
	Orders of knighthood	3,500	
Foreign Affairs.	Office expenses	7,050	49,350
	Salaries of ministers and consuls abroad	35,500	
	Cabinet messengers	1,800	
	Miscellaneous & unforeseen	5,000	
Grace and Justice.	Office expenses	8,200	130,300
	Supreme Court of Justice	10,500	
	Courts of appeal	15,500	
	Criminal courts	33,000	
	Civil tribunals	17,000	
	Offices of the courts and tribunals	26,600	
	Tribunals of commerce	600	
	Consulta of state	11,400	
	Miscellaneous	6,500	
Ecclesiastic Affairs.	Office expenses	5,500	8,530
	Support of churches and curates	1,000	
	Charities to religious orders	720	
	Repairs of churches	650	
	Festivals, missions, etc.	660	
Public Instruction.	Office expenses	3,260	48,420
	Theatres & public spectacles	11,800	
	Royal Museum, public libraries, institutes of the fine arts	18,240	
	Public instruction, universities, colleges, etc.	10,320	
	Provincial instruction expenses	4,800	
Finances.	Office expenses	6,475	2,254,420
	Civil list and royal household (without including income from crown lands)	307,040	
	Interest of public debt	960,000	
	Pensions, etc.	278,420	
	Custom-house, excise, and other indirect taxes	256,540	
	Stamp and registration offices	84,560	
	Post-office	38,650	
	Lottery	32,500	
	Railway	16,800	
	Sinking fund and domains	16,580	
	Mint	15,200	
	Miscellaneous (chiefly for collection of taxes)	241,655	
Public Works.	Office expenses	4,800	324,120
	Prisons, dungeons, and *Ergastoli*	108,250	
	Public roads and bridges' department	130,530	
	Harbours, etc.	22,850	
	Land improvement department	15,860	
	Provincial public works	30,680	
	Miscellaneous	10,150	
Home Office.	Office expenses	9,100	221,220
	Civil administration, viz., intendenti, sotto-intendenti, etc.	28,500	
	Charitable trusts	42,150	
	Public health	5,120	
	Scientific and artistic establishments	1,450	
	Woods & forests, & game	8,340	
	Miscellaneous and extraordinary	126,560	
Police			32,860
Navy			372,820
Army			1,954,340
	Total		L.5,410,680
	Revenue		5,300,866
	Deficit		L.109,814

These tables, even if they were less accurate than we take them to be, would always give a great insight into the state of the country, and the moral principles which guide its government. It will be seen that nearly one-sixteenth part of the whole revenue is derived from that most objectionable of all indirect taxes, lottery. The charitable trusts' property (*Fondi della Publica Beneficenza*), which in the course of ages has accrued from donations or bequests intended to be employed for the relief of the poor, gave an income of L.164,500; but of this sum only L.42,150, or less than one-third, were invested according to the original intentions of the donors and testators. More than one-sixth of the revenue goes to pay the interest of a public debt, chiefly incurred for the support of a foreign army called in to check the liberal aspirations of the people.

The army and navy expenses absorb L.2,327,160, or more than one-half of the whole revenue, whilst only L.324,120 are spent for public works, and L.48,120 for public instruction. In the department of public works, however, are included prisons and dungeons, the maintenance of which costs the country L.108,500, or a third of the amount classed under that head, and nearly as much as is spent in the salaries of all the judicial bench in the kingdom. And what is even more remarkable, among the expenses for public instruction we find an item of L.11,800 for theatres and public spectacles, leaving for the purposes of the public instruction only a sum of L.36,620, in which the expenses for the maintenance of the Museo Borbonico, the public libraries, and the Institute of the Fine Arts, as well as the office expenses, are included! The expenses of col-

lection and administration of the revenue amount altogether to about $14\frac{8}{10}$ths per cent.

By the Concordat of 1818 between Pius VII. and Ferdinand I., it was stipulated that no other religion but the Roman Catholic should be allowed a free exercise. There are about 2400 Jews, but they are allowed neither to hold property nor to acquire a domicile. The ecclesiastical establishment, which was formerly very extensive, having been somewhat reduced by the Concordat by the union of several of the smaller sees, consists at present of 22 archbishoprics, 19 on the continent and 3 in Sicily; 85 bishoprics, 72 in the continental and 13 in the Sicilian provinces; 5 abbacies, and 88 clerical seminaries. The archiepiscopal sees are, in Naples—Acerenza and Matera, Amalfi, Bari, Benevento, Brindisi, Chieti and Vasto, Capua, Conza, Cosenza, Gaeta, Lanciano, Manfredonia, Napoli, Otranto, Reggio, Rossano, Salerno, San Severino, Sorrento, Taranto, Trani; in Sicily, Messina, Monreale, Palermo. The abbacies are, in Naples, Monte Casino, Trinità della Cava, Montevergine; in Sicily, Monreale, San Martino. The archbishops of Naples, Capua, and Palermo, on being appointed to their sees, receive a cardinal's hat. Each diocese has its own administration, composed of the bishop as president, two senior canons, elected every three years by the chapter of the diocese, and an assessor. In every diocese there is a seminary for the education of young men intended for the church.

The monastic and mendicant orders, which were partially suppressed in 1807, were restored by Ferdinand I. on his return in 1815. Their numbers, of both sexes, are reckoned at present about 40,000.

The Concordat of 1818 received several important modifications in June 1857; not, however, by a new concordat, but by royal decrees revocable at pleasure. The jurisdiction of bishops was greatly extended; the trial of ecclesiastics for ordinary crimes was given to their respective ecclesiastical court; members of collegiate or cathedral chapters, curates, and members of religious communities, were granted the privilege of being buried in their own churches; article 826 of the code of civil laws, requiring the royal assent to any bequest in favour of a religious corporation, was abrogated, and public instruction was more completely placed under the control of ordinaries.

Public education is entirely in the hands of the priests, and is at a lower stand in the Two Sicilies than in any part of Italy; the attention of the government being directed not to foster, but to check it in every way. It has already been noticed that the item for public education in the budget is L.48,420, out of which L.11,800 are spent on theatres and other amusements.

By a law of Murat, in 1810, elementary schools were established in all the communes, for the sake of the primary education of boys and girls, who were taught reading, writing, arithmetic, geography, and the principles of religion; the girls also knitting and sewing. Since 1821, and more since 1848, most of those schools have been closed, or placed under the care of the parish priest, who entirely neglects them. In the capitals of some of the provinces there are royal colleges, superintended by the Jesuits, in which young men of the middle classes are educated. The course of studies consists of Latin, and sometimes Greek, mathematics, and elements of history and geography. In the seminaries young men intended for the church are taught Latin, metaphysics, and theology. The professors are all priests, and under the vigilance of the ordinary. Private teaching is forbidden, unless the teacher satisfies the ordinary, and the head of the local police, of his attachment to the throne and his abhorrence of new ideas, and receives from each of them an express permission to give lessons. Till very recently, there were four universities, at Naples, Palermo, Messina, and Catania, all of old foundation, for the higher branches of knowledge, and the conferment of academical degrees; the former frequented by the young men of the continental provinces, the three latter by the Sicilians. But as the concourse of many youths to Naples was a subject of alarm to the government, by a royal decree of April 1857, it was provided that only the young men of the two provinces of Naples and Terra di Lavoro should be allowed to go and take their degrees at the university of Naples; the others are compelled to take them in the colleges of their respective provinces. This decree, somewhat justifiable in principle, if there was no compulsion, and if there were means of obtaining a suitable education in the provinces, is calculated greatly to lower the standard of learning in the country; for it is only in Naples that able professors for the higher branches of knowledge can be obtained.

The superintendence of the public instruction of the whole kingdom is vested in two boards, *Giunte della Publica Istruzione*, one of them at Palermo, the other at Naples, and both under the control of the minister of religion and public instruction. Each *Giunta* is composed of a president, generally a bishop, and six members appointed by the king from among the professors of the university.

The whole kingdom is divided into 22 provinces, of which 15 include the continental possessions, and 7 the island of Sicily. Each province is divided into districts, *distretti*, and each district into *circondarii;* a circondario consists of one or more communes; some communes are an aggregate of several villages. The city of Naples is divided into 12 and Palermo into 6 circondarii. There are altogether 77 districts, 720 circondarii, and 2210 communes. There is no reliable census of the kingdom, the official returns that are occasionally published being very unsatisfactory. The last returns were published in 1856. A survey of the kingdom, begun under the French, having made as yet but little progress, the numbers given as the area of each province must be considered as merely an approximation.

The following table shows the name, extent, and population of each province, and the population of the chief towns:—

Provinces.	Area in square miles.	Population of 1856.	Capitals.	Population of 1856.
NAPLES.				
1. Naples	326	850,450	Napoli	409,658
2. Terra di Lavoro	1,959	774,523	Caserta	15,800
3. Abruzzo Ultra I.	976	239,429	Teramo	8,600
4. Abruzzo Ultra II.	1,908	355,683	Aquila	9,700
5. Abruzzo Citra	840	323,574	Chieti	17,000
6. Molise, or Sannio	1,422	376,935	Campobasso	10,400
7. Principato Citra	1,670	580,660	Salerno	18,000
8. Principato Ultra	1,064	373,736	Avellino	23,000
9. Capitanata	2,359	332,294	Foggia	24,000
10. Terra di Bari	1,743	538,103	Bari	28,000
11. Terra d'Otranto	2,504	431,949	Lecce	19,400
12. Basilicata	3,134	517,354	Potenza	12,000
13. Calabria Citra	2,160	452,766	Cosenza	14,000
14. Calabria Ultra II.	1,704	395,029	Catanzaro	13,200
15. Calabria Ultra I.	1,152	334,872	Reggio	16,000
Total	24,921	6,877,357		
SICILY.				
16. Palermo	1,500	541,326	Palermo	200,000
17. Messina	1,048	384,664	Messina	108,000
18. Catania	1,332	411,832	Catania	60,000
19. Noto	1,120	254,593	Noto	14,200
20. Caltanissetta	900	185,531	Caltanissetta	18,500
21. Girgenti	1,040	250,795	Girgenti	22,400
22. Trapani	1,027	202,279	Trapani	26,000
	7,967	2,231,020		
Naples	24,971	6,857,357		
Total	32,938	9,088,377		

The first enumeration of the inhabitants of the conti-

nental part of the kingdom was ordered by Alfonso I. of Aragon, for the purposes of taxation, and was finished in 1465. It was found that there were 232,896 *fires*, or families, which, calculated at the rate of six heads per family, gave 1,397,376 souls, and with the addition of 250,000 for the city of Naples and its suburbs, a total of 1,647,376. The increase from that time, as far as it can be ascertained, was as follows:—

1595.	1768.	1788.	1816.
3,628,500	4,029,620	4,815,000	5,114,613
1825.	1835.	1845.	1855.
5,545,804	6,013,171	6,451,406	6,858,357

By comparing these numbers, it will be seen, that in 40 years, from 1816 to 1855, it has increased a little more than one-third, and that it would, therefore, take about 120 years to double it. During that period, however, the steady, though slow, increase was checked three times, in 1817, when an epidemic spotted fever caused the number of deaths to exceed that of births by 142,887, and in 1836-37, and 1854-55, when the cholera caused altogether a diminution of 82,964 in the births, as compared to the deaths. The slow increase from 1788 to 1816, being only 1-16th in 28 years, is accounted for by the civil and foreign wars, and the revolutions to which the country was a prey during part of that time. The population of Sicily in 1505 was reckoned at about 600,000. In 1615 it had nearly doubled, being 1,107,234; but after a century, in 1714, it was only 1,133,163. In 1825 it was 1,714,000, and in 1854, 2,231,020, showing an increase of about one-third in thirty years, which would cause it to double in less than a century. On the 1st of January 1856, the population of the whole kingdom was 9,088,377.

The various states which form the kingdom of the Two Sicilies played an important part previous to the rise of the Roman power. Though the existing records of their early history are very scanty and unsatisfactory, yet enough remains to prove that some of the small independent states into which Southern Italy was divided had attained great intellectual development and material prosperity. Some antiquaries have seen traces of Phœnician settlers in several places at a very remote period; but there is no doubt that that high degree of civilisation in the country was owing to the numerous Greek colonies which, between the eighth and the seventh centuries B.C., if not earlier, had settled in Sicily, and on the shores of the Tyrrhenian, the Ionian, and the Adriatic Sea, which hence had the name of Magna Græcia. An account of those colonies, and an admirable relation of the great Athenian expedition against Syracuse in B.C. 427, and its disastrous results, may be found in Grote's *History of Greece*, vols. iii. and viii. The conquest of the continental provinces by the Romans, which may be said to have begun with the first Samnite war in B.C. 343, was completed with the final defeat of Pyrrhus, near Beneventum, in 225, who had been called in to their assistance by the Tarentines, and the fall of Tarentum three years later. The possession of Sicily was the subject of a long and obstinate contest between the Romans and the Carthaginians; its total submission and reduction into a Roman province was only accomplished by the taking of Syracuse by Marcellus in B.C. 212, and the surrender of Agrigentum to the Consul Lævinus in 210.

At the dissolution of the Western Roman empire, Sicily and Naples fell first under Genseric and Odoacer, and at the defeat of the latter by Theodoric, under the Goths, until Justinian, through his generals Belisarius and Narsis, regained the whole of Italy, and put an end to the Gothic kingdom in 553. The Greeks, however, did not long enjoy their conquest. The Longobards descended into Italy under Alboin, in 568, and extended their conquests into Southern Italy, where they founded the powerful duchy of Benevento. The whole of the present kingdom of Naples with the exception of a few cities along the coast which remained under the Greeks, and the towns of Naples, Gaeta, and Amalfi, that erected themselves into independent republics under dukes appointed by the Greek emperors, fell under the dukes of Benevento for nearly 200 years. In the ninth century, whilst that Duchy was weakened by internal feuds, and by the erection of the independent Longobard principalities of Capua and Salerno, there was added a new element of confusion and disorder, in the depredations that were carried on by the Saracens, who had first landed in Sicily in 827, and in a few years conquered the whole island from the Greeks. From Sicily the Saracens began their attacks on the continental shores, seized Bari and other important cities, and strongly fortified themselves in several places. The incursions of the Hungarians, and the occasional arrival of German hordes under the successors of Charlemagne, contributed to increase the state of general confusion, constant warfare, and anarchy.

In the midst of these struggles a new element appeared in the field. The Normans, who had already made themselves conspicuous in the north of Europe, found their way to the south. The two conquering races of the middle ages, and the representatives of the Roman empire in the East, the Saracens, the Normans, and the Greeks, first met on the classic soil of southern Italy, and northern strength and daring gained the victory.

In the beginning of the eleventh century a body of Normans offered their assistance to Sergius, the Greek duke of the city of Naples, against Pandulf, the Longobard prince of Capua. As a reward for their past and a guarantee for their future services, they received a tract of land midway between those two cities, where, in 1030, they established themselves and built the city of Aversa, of which their leader Rainulf was the first count. The news of their success soon brought other bodies of bold and greedy adventurers from Normandy, with the twelve sons of Tancred, Count of Hauteville, at their head. After at first joining sometimes the Longobards and sometimes the Greeks against each other, or against the Saracens, at length they began to fight on their own account, and soon acquired such power that, at a general assembly they held in the city of Matera in 1042, they proclaimed William Bras-de-Fer, eldest son of Tancred, *Comes Apuliæ*. He was succeeded in 1046 by Drogo, and in 1050 by Humphrey, his brothers.

The successes and the rapacity of the Normans, who did not respect the property of churches and monasteries, alarmed Pope Leo IX., who proclaimed a sort of crusade, and led in person against them a large army of Italians, and some Germans contributed by the Emperor Henry III. Leo began his campaign by a pilgrimage to the monastery of Montecasino, whence he descended into the Apulian plains. In vain the Normans, who were but few in number, sued for peace; the Pope was inexorable. The two armies met on the plain near Civitate, on the right bank of the Fortore, on the 18th of June 1053. Despair gave the Norman arm additional strength; the motley crowd brought together by the preaching of the monks fled in utter disorder; Leo himself fled to Civitate, but, being refused shelter by the inhabitants, fell into the hands of his enemies. The crafty Normans, however, far from making him a prisoner, knelt as they approached, imploring his pardon and benediction, and treated him in their camp with so much respect that Leo soon was reconciled to the race, and, as if the kingdoms of the earth were the Pope's, granted to the brothers Humphrey and Guiscard, their leaders, an investiture not only of what they were already masters of, but of the whole of Apulia, Calabria, and Sicily, which they might wrest from the Greeks and the Saracens. Leo was canonized at his death.

The battle of Civitate is a most important event in Italian

history. It not only firmly established the Norman power, and led to the foundation of the kingdoms of Naples and Sicily, but originated that memorable investiture, which, by causing the Popes to claim Naples and Sicily as *fiefs* of the Holy See, and apply to them the rules of feudal law, led to their constant interference in the affairs of the country, and to the changes of dynasties through their instrumentality; it became, in short, the clue to great part of the history of the Two Sicilies. It was also owing to the alliance of interests formed after that battle, that, when Pope Gregory VII., in his famous contest with the Emperor Henry IV., was defeated, and besieged in the castle of St Angelo, Robert Guiscard went with his Normans to release him, and pillaged and burned the whole of Rome from the Lateran to the Capitol.

Robert Guiscard, who succeeded Humphrey in 1057, having conquered Calabria from the Saracens and the Greeks, in 1059 assumed the title of Duke of Apulia and Calabria, and in 1085 transmitted his power to his son, Roger Bursa, whose son William died without issue in 1127. Meanwhile Roger, a younger son of Tancred of Hauteville, had conquered the island of Sicily from the Saracens, and assumed the name of Great Count, which he transmitted to his son Roger, who became the founder of the monarchy. Roger, on the death of William in 1127, succeeded to the dukedom of Apulia and Calabria, of which he obtained the investiture from Pope Honorius, by confirming to the Holy See the possession of Benevento, which Leo IX. had obtained from the Emperor Henry III. in 1050, in exchange for Bamberg. In 1130, on making himself master of Naples, at a general parliament assembled at Salerno, he resolved to assume the title of King of Sicily and Apulia; and the antipope Anacletus, who was anxious to secure Roger's support against his competitor, Pope Innocent II., with a bull of September 1130, gave him the corresponding investiture.

As a summary of the whole history of the country, into the details of which the limits of this article forbid us to enter, we give at the end a chronological table, showing the various dynasties from the establishment of the monarchy to the present day, the duration of the reign of each sovereign, and when Naples and Sicily were united under the same ruler, and when governed by different kings.

Roger made Palermo the royal residence, and at his death transmitted the crown to his son William, surnamed the Bad, who was succeeded by his son William, surnamed the Good. At the death of the latter in 1190 without issue, the Emperor Henry VI., of the house of Hohenstaufen, claimed the kingdom in right of his wife Constance, the daughter of Roger. The Sicilians, however, abhorring German rule, chose Tancred, a natural son of a son of Roger, and, on his premature demise, his son William, a minor. Henry invaded the country, and exercising great severity, reduced it to his authority, and compelled William III., in whom the Norman dynasty ended, to abdicate. Henry did not enjoy long his conquest; his widow, Constance, governed the country for a year, and at her death, in 1198, she left her son, afterwards emperor of Germany (as Frederick II.), then only three years old, under the regency of Pope Innocent III., who entrusted the education of Frederick to four national bishops, and checked several attempts at insurrection of the powerful barons. At the death of Innocent III., in 1215, the strange alliance between a Pope and the head of a Ghibeline family was broken, and a long contest began, which ended in the extinction of the house of Hohenstaufen, and the establishment of the Angevine dynasty at Naples.

Frederick was born at Iesi, and though of a German family, he was in language, character, and affections an Italian. He encouraged learning, and founded schools and universities. He was fond of literature and poetry, and spoke with equal facility Latin, Greek, Italian, German, French, and Arabic. It was at his court in Sicily that the Italian language, hitherto regarded only as a corruption of Latin, first rose to importance, and was polished by the poets, who were encouraged by him to make use of it. Some of the earliest poetry in Italian is by Frederick himself, and his sons Manfred and Enzo. He had a taste for philosophy, and great independence of opinion; but his want of faith in the sacred character of the Roman Church and the sanctity of popes, whose temporal encroachments he was compelled constantly to withstand, countenanced the attack of infidelity brought against him by the Guelf party. Cruelty, though not more than usual at that age, ambition, a suspicious disposition, and great partiality for the Saracens, whom he found useful in opposing the Court of Rome, were the leading faults of his character. He restored order in the Two Sicilies, and established a prosperity not to be found elsewhere in Europe at that time.

The *Constitutiones Siciliæ*, a body of statutes, which he enacted at different times, chiefly by the advice of his famous secretary, the great and unfortunate Pier delle Vigne, to whom refer these beautiful lines of Dante—

> "Io son colui che tenni ambo le chiavi
> Del cor di Federico, e che le volsi,
> Serrando e disserrando, sì soavi
> Che dal segreto suo ogni altro uom tolsi"—
> (*Inferno*, xiii., 58)

are a monument of legislative wisdom far beyond his age. We find him, among other things, abolishing as a barbarous custom the *droit d'aubaine*, or seizure by the state of the property of a stranger, not naturalized, at his death—a practice abolished only in our own times by some of the most civilized nations.

In 1225 Frederick married Iolanda de Lusignan, heiress of the kingdom of Jerusalem, from whom the kings of Naples inherited the title of kings of Jerusalem. After thirty years of almost unremitting contest with the popes and the Guelf party, which wore out his bodily as well as mental energy, Frederick died, only fifty-six years old, in December 1250, in the castle of Fiorentino in Capitanata, anathematized by the church, and broken-hearted at the treason of many whom he believed his friends, the disasters of his party, the decline of his power, and the refusal of the Bolognese to set at liberty his favourite natural son Enzo, whom they had made a prisoner in 1249.

Conrad, his son, had a very short reign, and died in 1254, leaving an only child, Conradin, in Germany. Manfred, another natural son of Frederick, assumed then the government of the country, at first as guardian of Conradin, and afterwards, on the false reports of Conradin's death, in his own name.

Manfred became the leader of the Ghibeline party, and more obnoxious than ever to the Popes, who resolved to get rid of such an unfriendly neighbour. At length, Urban IV., who was raised to the Papal chair in 1261, and was an inveterate enemy of the house of Suabia, excommunicated and deposed Manfred as a usurper, and, availing himself of the feudal authority claimed by the Holy See, offered the Sicilian crown for sale among the princes of Europe. It was ultimately handed over as a fief, on a yearly tribute of 8000 ounces of gold, to Charles of Anjou, the brother of Louis IX. of France.

Urban did not live to see the fulfilment of this arrangement, which however, after his death was furthered by every temporal and spiritual means at his disposal, by his successor, Clerment IV., who was by birth a provençal, and greatly devoted to the house of Anjou. Urged on by the restless ambition of his wife Beatrice, a daughter of Raymond Berenger, last Count of Provence, whose three elder sisters were married to the sovereigns of England, France, and Germany, Charles arrived in Rome in December 1265,

with an army composed of the flower of the knights of France, and on the 1st of January 1266, was crowned by the cardinals as king of the Two Sicilies. After a short stay he entered the kingdom; and having had the frontier strongholds of Ceprano, Arce, and San Germano surrendered by the treachery of their commanders, he marched upon Benevento, where Manfred was encamped with his army. Charles gave battle the same day, February 26. The valour of the Swabian and Saracen followers of Manfred was not proof against the impetuous attack of the French and the treacherous desertion of his Apulian barons. Manfred fell in battle, and his remains, on account of the anathema against him, being denied Christian burial, were at first buried under the bridge of Benevento, and afterwards, at the instigation of the Archbishop of Cosenza, removed into a lonely valley of the Tronto, beyond the frontier of the kingdom. Every reader of Dante is familiar with the beautiful passage alluding to Manfred in *Purgatorio*, iii., 124.

Scarcely had Charles been two years in the possession of his throne when young Conradin, the son of Conrad, advanced at the head of an army from Germany, and supported by the Ghibeline cities of Lombardy, to attack him. The hostile armies met on the plain of Tagliacozzo on the 22d of August 1268. Victory seemed at first to be for Conradin; but whilst the youth was rejoicing in the camp over his success, Charles sent against him a fresh detachment which he had kept in reserve, and the day was completely lost. Conradin succeeded in escaping, but was betrayed into the hands of Charles by a Frangipani, an old follower of the Hohenstaufen, with whom he had sought refuge. Taken to Naples, and subjected to a mock trial, Conradin, the last scion of the Hohenstaufens, the descendant of emperors, at the age of seventeen, by the advice of the Pope, perished, together with his cousin Frederick of Austria, by the hand of the executioner, in the Piazza del Mercato at Naples, on the 29th of October 1268. From his scaffold he called his heir Constance, daughter of Manfred; and, challenging an avenger, he flung his glove among the crowd, which was picked up and faithfully conveyed to Peter of Aragon, her husband. Charles disgraced himself by personally assisting at the execution. By such means was the Angevine race established in the Two Sicilies.

After the utter annihilation of the Swabian party on the continent, Charles wreaked his vengeance upon the island of Sicily, which had declared in favour of Conradin. Augusta and other towns, which offered some resistance, were destroyed and all their inhabitants slaughtered, and the whole island was ruled with an iron sceptre. The oppressed and discontented people applied to the Pope for redress, but without effect. Upon this John of Procida, a nobleman from Salerno, whose estate had been confiscated on account of his strong attachment to the Hohenstaufens, resolved to put an end to the sufferings of Sicily. In execution of his plans of revenge, he first applied to Peter of Aragon, who showed a disposition to assist him, but could do nothing from the want of pecuniary means. Procida undertook to procure those means, and first visited Sicily, where he found all prepared to resist Charles, and where he encouraged the hope of revenge. He then proceeded to Constantinople, and presented himself to the Emperor Michael Palæologus, who had been alarmed by Charles with threats of invasion, and from whom he obtained promises of a large sum to be sent to Aragon. Having received the money, he returned to Peter, who immediately commenced warlike preparations, on the pretext of making an attack upon the Moors in Africa.

Whilst these warlike preparations were going on, the arrogant and oppressive behaviour of the French gave rise to a sudden outburst of popular indignation, which put an end to their misrule in Sicily. On the afternoon of Easter Tuesday, the 31st of March 1282, the inhabitants of Palermo went, according to their custom, to hear vespers at a church outside the town, where they gathered in great numbers, and, with a mixture of gaiety and religion, enjoyed dancing and eating. Among them was a girl of great beauty, with her parents and her acknowledged lover. A Frenchman, called Drouet, under pretext that she carried arms concealed under her dress, seized her, and thrust his hands into her bosom. The girl fainted away in the arms of her betrothed, who, enraged, exclaimed, "Oh, let us kill these French!" His voice was not raised in vain. An unknown youth fell upon Drouet and killed him, and he himself was instantly put to death by the other Frenchmen. A thousand voices from the assembled crowd exclaimed, "Death to the French!" and the fight became general. A dreadful massacre ensued, in which all the French were put to death. In their rage the inhabitants sacrificed all, not excepting the aged, the females, and the children; and even those women who had connected themselves with Frenchmen were likewise murdered. This horrible event has ever since been known by the name of the Sicilian Vespers. The other cities of Sicily, with the exception of Sperlinga, followed the example set at Palermo, and wherever a Frenchman could be found he was instantly put to death.

Charles, on receiving the horrible intelligence, hastened from Orvieto, where he was on a visit to the pope, to Naples, and having collected his whole forces, prepared to pass over to Sicily. In July he appeared before Messina, and at first gained some advantages; but the spirit of the inhabitants was so roused that they defended themselves with the most energetic courage, even the women and children partaking with the men in the dangers as well as the privations and sufferings of a siege.

Soon after the breaking out of the insurrection, a kind of federal republic had been proclaimed under the patronage of the Church of Rome; but the hostility of the Pope, who lent spiritual and temporal support to Charles, and the news of the first reverses at Messina, caused the parliament assembled at Palermo to offer the Sicilian crown to Peter of Aragon, who was with a considerable army on the African coast. Peter at once accepted the offer, and on the 30th of August landed at Trapani, and thence proceeded to Palermo, where he was received with rapturous joy. Charles, disturbed by this occurrence, became also alarmed for the state of Calabria, and having instantly embarked his troops, leaving his military stores behind him, sailed across the strait; but before he reached the continent his fleet was attacked by that of Peter, under the command of his admiral, Roger de Loria, who captured twenty-nine of his vessels, and then ravaged the coast of Naples. Peter was received with exultation in Messina, and assumed the government, although the pope issued a bull, placing him and the Sicilians under the ban of the church. The next year Constance arrived with her sons, and was acknowledged as the legitimate inheritor of the crown. Although Charles continued to make attempts to regain his authority in Sicily, they were all unavailing; and the two kingdoms were separately ruled during a hundred and sixty years.

Robert, the grandson of Charles, who in succession filled the throne of Naples in the year 1309, was a patron of letters, and the friend of Petrarch and Boccacio. After his death, in 1343, in the reign of his granddaughter Joanna, great commotions broke out in Naples. She had married Andrew of Hungary, who was murdered at Aversa, not without strong suspicion that his wife had been participator in the crime. Owing to this charge, the Pope, Urban VI., conferred the crown of Naples upon Charles of Durazzo, a Hungarian, who had married a sister of Joanna. He was a short time acknowledged as king of Naples and Hungary; but was assassinated in the latter kingdom in 1386.

At his death, two competitors for the crown appeared in Naples; Ladislaus, his son, and Louis of Anjou, an adopted or illegitimate son of Joanna. Ladislaus, after some struggles, conquered Louis. He also made himself at one time master of Rome, and aimed at the sovereignty of all Italy; but his projects were terminated by death in the year 1414. His sister, Queen Joanna II., at first adopted King Alfonso of Aragon as her heir, but afterwards by her will called to the throne René of Anjou, who succeeded her. Alfonso, however, who was the heir of the Hohenstaufens through the female line, and was already king of Sicily, attacked and expelled René from the kingdom, put an end to the Angevine dynasty, and reunited Sicily and Naples.

The dominion of the house of Aragon, after the death of Alfonso, was a period of misery to the country. Wars were frequent and destructive, the exchequer was impoverished, and the most noble and influential families were crushed, especially after the conspiracy of the barons, headed by the Count of Sarno and Antonello Petrucci. The descent of Charles VIII. into Italy gave the first blow to the dynasty of Aragon, which was at length overthrown by a combination of France and Spain.

By the treaty of Granada, signed November 11, 1500, and confirmed by Pope Alexander VI. and a conclave of cardinals in the following year, Ferdinand the Catholic of Spain, and Louis XII. of France, agreed to divide the kingdom of Naples between them. The treaty provided that the King of France should possess the city of Naples, the Terra di Lavoro, the three Abruzzi, and half the revenue produced by the Tavoliere di Puglia, with a confirmation of the title of King of Naples and Jerusalem, which he had previously assumed. On the other hand, the King of Spain, who had for many years been king of Sicily as the successor of his father John II., was to possess the three Calabrias and Apulia, and the remaining half of the revenue of the Tavoliere, with the title of Duke of Calabria and Apulia. The possession of the provinces not mentioned in the treaty soon led to a war between the contracting parties. Hostilities commenced in June 1502, and in little more than eighteen months the French were defeated in four battles, and the whole kingdom, by the military genius of Gonsalvo de Cordova, became, like Sicily, a Spanish possession.

During the two succeeding centuries, both portions of the kingdom of Naples remained under the government of the kings of Spain. The parliaments, which had originated with the Normans, and were occasionally convened both in Naples and in Sicily, fell into desuetude, or were only summoned to vote money. The feudal system grew worse, an extension of their privileges, especially the power of life and death over their vassals, being granted to the barons with a view of securing their service in the wars, and their votes of money. The city of Naples had almost the whole administration of the kingdom centred within itself, but under the absolute control of the viceroy. By such means the power of the crown was gradually extended. The imposition of new taxes, and the oppressive modes of enforcing the payment of them, led sometimes to turbulent scenes in the capital, most of which were speedily suppressed; but one of them was of so singular a character as to deserve a short relation.

In the year 1647 it was thought necessary to impose some tax upon all fruit sold in the city; which, being in summer the chief food of the poor, caused great uneasiness, but no immediate insurrection. A fisherman, named Masaniello, whose wife had been recently detected in smuggling some flour into the city, and fined for it, had conceived an implacable hatred against the suggesters, the farmers, and the collectors of the new tax. He was a powerful speaker, and a leader of one of the parties of the populace who had agreed to have a sham fight upon a festival. On that day, the 7th of July, in consequence of a quarrel between the tax-collectors and some fruit-sellers from Pozzuoli, one of whom was a brother-in-law of Masaniello, the latter first roused the populace, and excited them to destroy the office where the tax was collected, and the dwellings of those who had proposed or farmed it. In the course of the rioting, the viceroy, instead of ordering the Spanish guards to suppress the disturbance, fled, and was personally insulted; but at length he escaped to a sanctuary, where the archbishop joined him, and they conjointly issued a notice that all taxes on provisions should be abolished. Besides this, an attempt was made to gain Masaniello by an offer of a pension. But he refused to accept the offer, declaring that if the viceroy kept his word he would find the people obedient subjects.

On the following day, however, no taxes being abolished, the followers of Masaniello committed some violent outrages, which induced the viceroy to enter into a kind of treaty with this leader, who, though half naked and in rags, found himself at the head of 100,000 armed men, filled with fury. Some of his followers having been bought over by the court, agreed to kill him; and whilst he was in treaty with the archbishop, in the church of the Carmire, the attempt was made; but it failed, and those who were thus shown to be traitors to their chief were instantly put to death. The failure of the attempt greatly strengthened the power of Masaniello, who exercised it with much appearance of fairness and impartiality. The viceroy was fearful that the French might take advantage of the commotion, and create some annoyance, and therefore hastened to make peace with the leader of the insurrection. On the fifth day after it broke out, a treaty was concluded, by which it was stipulated that the taxes imposed since the reign of Charles V. should all be abolished; that in future no new taxes should be levied except by electors; that the people were to elect as well as the nobles; that an act of oblivion should be passed, and the people remain in arms till the ratification of the treaty was completed.

Great rejoicing followed this arrangement. Masaniello having repaired to the viceroy, was appointed captain-general, and induced to change his dress for more appropriate apparel; he also received a present of a gold chain. The following day he began to exercise the authority of a sovereign, judging all crimes, whether civil or military, and ordering to instant execution, on a gallows he had erected, those whom he had doomed to death. It is said that in these summary proceedings no innocent person suffered, and no guilty person escaped. His grandeur was but of short duration. In two or three days he became distracted and delirious, and committed some most extravagant actions; and on the 18th of July he was put to death, with the consent, if not by the orders, of the viceroy.

The tumult did not, however, terminate with the death of its author. In the capital, as well as in all the other cities of the kingdom, the people rose and drove out those Spaniards who were found in them. The Duke of Guise, who happened to be at Rome, was induced, at the instigation of the pope, to offer his services to the Neapolitans against the Spaniards; and to this he was further encouraged by having some distant pretensions to the throne. The Spaniards, in the meantime, made a vigorous attack on the city of Naples, but were repulsed by the people, who thereupon formally renounced their allegiance to the Spanish family. In a short time, however, a new viceroy, Count d'Oniate, arrived from Spain. He took the city by surprise, made the Duke of Guise prisoner, and thus frustrated all the designs of France against the Spanish power in Naples.

But the rule of Spain, which neither the popular movement of Masaniello, nor an aristocratic conspiracy at the beginning of the eighteenth century planned by the Prince of Macchia, succeeded in overthrowing, was

brought to an end by the war of the Spanish Succession. In 1707, after the defeat of the French army in Lombardy by Prince Eugene, a body of 5000 infantry and 3000 German cavalry, under the command of Count Daun, entered the Neapolitan frontier by Palestrina, and without encountering any resistance from the Spanish viceroy, took possession of the kingdom. By the treaties of Utrecht (April 1713), and Rastadt (March 1714), the Emperor Charles VI. was maintained in the possession of Naples, and Sicily was ceded by Spain to Victor Amadeus, Duke of Savoy. The latter part of this arrangement, however, was altered after the death of Louis XIV., when Cardinal Alberoni, in endeavouring to retrieve the Spanish loss, seized upon Sardinia and Sicily, and thereby gave origin to the quadruple alliance of Austria, England, Holland, and France. After two years' war, by a peace made in 1720, Sicily was also given to the emperor, and Amadeus of Savoy received a poor compensation in Sardinia.

The contest for the Spanish Succession had only substituted an imperial for a Spanish viceroy over the Two Sicilies; but the war for the succession of Poland (1733–1738) gave them national independence. The Spanish Infant Don Carlos, a younger son of Philip V., by his second wife Elizabeth Farnese, with an army of 16,000 infantry and 5000 cavalry, under the command of Count de Montemar, entered the kingdom in 1734, and having defeated the Austrians near Bitonto on the 24th of the following May, seized also upon Sicily, where, on the 3d of June 1735, he was crowned at Palermo as king of Naples and Sicily, and founded the Bourbon dynasty still reigning over the country.

Charles had not been long acknowledged as king by the treaty of Vienna of November 1735, when he had to defend his possessions in the war that broke out in 1743 on the death of the Emperor Charles VI. for the Austrian succession. But the defeat of the Austrians at Velletri in August 1744, and afterwards the treaty of Aix-la-Chapelle in 1748, firmly established him on the throne.

The reign of Charles, through the wise administration of his minister Tanucci, a Tuscan advocate who had followed him to the conquest of the kingdom, was marked by great reforms in every branch of the administration, and by attempts to raise the moral character of the nation from the low ebb into which it had fallen under the viceroys. The state of the country was such, that the judicial census gave 30,000 thieves in the city of Naples alone, and poisoning was so prevalent, especially by women, that Charles deemed it necessary to institute a special court, called *Giunta de' Veleni*, for their punishment. Charles founded a naval college, a tribunal of commerce, a vast house of refuge for the reception of the poor of all the kingdom, and the knightly order of St Januarius. He opened the first roads in the kingdom, built several military barracks, and the large theatre called from him San Carlo; and began and partly built the royal palaces of Caserta, Capodimonte, and Portici. He attempted to mitigate the barbarity of the criminal laws, and to check the abuses of the feudal system; and by a Concordat, agreed upon in 1741 with Pope Benedict XIV., established on a better footing the ecclesiastical hierarchy and policy in the country. He also promoted and encouraged learning in every way, and on the discovery of Pompeii, Herculaneum, and Stabiæ, he founded the Ercolenese Academy for the explanation of the antiques brought to light, and began the vast collection called afterwards Museo Borbonico.

Whilst carrying on these reforms, Charles was called to the throne of Spain by the death of Ferdinand VI. without issue in 1759. Before leaving Naples he regulated the royal succession, and excluding his eldest son Philip on account of imbecility, and his second son Charles, who was to succeed him in Spain, he called to the throne of the Two Sicilies Ferdinand, his third son, then only eight years old, and appointed a regency for the government of the country. Charles, who was VII. of that name in Naples and III. in Spain, is generally known in Neapolitan history as Charles III.

Ferdinand IV. followed under the regency the steps of his father. On attaining his majority, his first act was the expulsion of the Jesuits from the kingdom in 1767, in compliance with the orders from Spain. The following year he married Caroline, a daughter of the Empress Maria Theresa, and a sister of Mary Antoinette of France. Caroline, who was beautiful, clever, and fond of power, soon acquired great influence over her indolent and uneducated husband, and being admitted into the council of state by an express stipulation in the marriage articles, she became the chief ruler of the whole policy of the government. The liberal and enlightened reforms initiated by Charles were, however, continued, and the royal attention was particularly turned to public education. The University of Naples, founded by Frederick II., was re-constituted on a better plan, and the chairs filled with the most able men in the country. The statutes of the Academy of Science and Literature were altered and remodelled. A college of nobles was founded in every province, in which the lectures were public, and the professors chosen by public examination; and every commune was ordered to appoint masters for primary instruction. These schools were all secular, and the ordinaries had neither voice nor power of interfering in them. Men of learning were encouraged; Pagano published his *Political Essays;* Filangieri his *Science of Legislation;* Genovesi his *Metaphysics, and Lessons on Political Economy*, works very remarkable for their age. At the same time, to encourage agriculture, the mortmain laws were promulgated, which prohibited any increase of the landed property of religious corporations, and favoured the passage of the lands they were possessed of into secular hands.

These improvements, however, were counterbalanced by some evils. Tanucci lost all influence, and the personal favourites of the queen, Chevalier Medici and Sir John Acton, who had settled at Naples and attained the rank of general and minister of marine, governed the country at their will. The personal conduct of the queen, and the example of the whole court, greatly lowered the moral tone of society, and made the Neapolitan aristocracy proverbial for their profligacy.

Such was the state of the country at the breaking out of the French Revolution in 1789. As a narrative of the occupation of Italy by the French has been given in this work under the heads FRANCE and GREAT BRITAIN, it is not necessary here to do more than briefly notice the principal events from that time to the restoration of the Bourbons in 1815.

The French Revolution effected an entire change in the course hitherto pursued by the Neapolitan government; which, as French affairs became worse, so grew more suspicious and watchful, till at length, after the execution of the royal family, it burst forth into open persecution against any one who had shown enthusiasm for the new doctrines.

In July 1793, Ferdinand entered into a secret treaty with England, which being acceded to by other powers, the Two Sicilies found themselves included in the vast European confederation against France. To meet the expenses of the war, the government resorted to extraordinary means and taxes. Subsidies were demanded and enforced from every community, corporation, and wealthy proprietor; a tax of 10 per cent. was imposed upon predial revenues; a large amount of church property was seized upon and sold; and all churches, monasteries, and private citizens were ordered to deliver over their plate, and receive in return bank certificates, payable after some years. To avoid any evasion of this law, buried treasures were

declared confiscated, and one-fourth of them awarded to the discoverer. The bank certificates were, however, rendered a mockery by a most disgraceful act of spoliation. There were in Naples seven banks, belonging to corporations, in which people were in the habit of placing their money, and receiving in return a promissory-note, which, being payable on presentation, circulated like cash, and often even at a premium, from its convenience and safety in carrying large sums. The cash deposited in these banks was gradually and secretly seized by the government, and the theft concealed some time by causing the bank officials to fabricate fresh paper. Suspicion having arisen of what was going on, the depositors hastened to claim payment; but the coffers being drained, payments were refused, and the promissory-notes at once fell to a discount of 85 per cent. More than L.12,000,000 of hard cash had been purloined, and thousands of families reduced to beggary.

Extraordinary measures were also adopted, both to silence the general indignation caused by such steps as these, and to smother the spreading of the new French ideas. An exceptional tribunal was created, called *Giunta di Stato*, for the trial of persons accused of treason. The proceedings in it were inquisitorial and secret; the proofs given in writing; secret and anonymous denunciations accepted as evidence; paid spies, servants, and even children, admitted as witnesses. The king appointed the advocate for the prisoner, who was not allowed to speak in his own defence; and the sentence—pronounced with closed doors, and not subject to appeal—was carried into immediate execution. Vincenzo Vitaliano, Emmanuele de Deo, and Vincenzo Galiani—three youths of good family, 22, 20, and 19 years old—fell the first victims to the cause of Neapolitan freedom, a cause which gathered strength from persecution; for though thousands have since died for it on the scaffold, in dungeons, and in exile, the aspirations for a liberal government are as ardent as they were more than half a century ago.

These measures were chiefly, if not entirely, the work of the queen and her favourite ministers, Acton and Medici, whilst the indolent king spent his time in hunting and carousing. But hard times were at hand. The events of the war were not favourable to the Bourbons. After some checks and a hollow peace, signed at Paris, with Buonaparte and the Directory in October 1796, Ferdinand raised a new levy of 40,000 conscripts, and, joining a new confederation against France, poured with a large army, under General Mack, into the Papal States, then occupied by the French, and, without encountering the enemy, entered Rome on the 29th of November 1798, and committed all sorts of excesses. In a few days the Neapolitan army was routed; Ferdinand fled in disguise to Caserta; and on the 20th December the French, under General Championnet, crossed the Neapolitan frontier. Such terror seized the king and the royal family, that, in spite of the advice of Sir William Hamilton and Nelson, on the morning of the 21st, they all sailed for Sicily. Championnet, with 22,000 French, after a week of desperate resistance from the lazzaroni, roused by the friars and priests, entered Naples on the 23d January 1799, and proclaimed the Parthenopean Republic.

The various acts of the republican government during its short existence; its overthrow by Cardinal Ruffo on the 14th of June 1799; the unutterable horrors, in the name of religion and loyalty, committed by the undisciplined masses under the cardinal's flag in their progress from Calabria to Naples; the wholesale massacre and pillage on the taking of Naples; and the state trials and executions that followed them, as well as the other events down to 1825—are graphically and touchingly related by a national historian, Pietro Colletta, who was partly an eye-witness and partly an actor in them, to whose work any one who takes an interest in them may refer with pleasure.[1]

When the royalist army entered Naples, the leading men who had taken a part in the republican government sought refuge in the castles Nuovo and Dell' Uovo, and entered into negotiations with the king's lieutenant, Cardinal Ruffo; but not trusting to him alone, they required that the capitulation should also be agreed to and signed by Captain Foote, in command of the British fleet in the harbour, and by the leaders of the Russian and Turkish forces. By the terms of the capitulation, the republican garrison might either embark for Toulon, or remain in the kingdom, secure from molestation for themselves and their families. When Queen Caroline read in Palermo these terms, and saw her hopes of vengeance frustrated, she entreated Lady Hamilton to go in pursuit of Nelson, who was sailing towards Naples, with letters to him from herself and the king, and to prevail upon him to revoke the treaty, as sovereigns could not stoop to capitulate with rebellious subjects. Nelson at first shrank with horror from the demand, but, unfortunately for his name, he yielded at last to the allurements of Lady Hamilton, and broke the capitulation. Cardinal Ruffo himself was disgusted at the violation of public faith. Admiral Caracciolo was subjected to a mock trial by court-martial, and hung on board Nelson's flag-ship. The republicans, who had embarked in several ships, and were sailing for Toulon, were stopped; eighty-four, marked as victims, were taken out of their number, chained two and two, subjected to a mock trial, and eventually executed. Mario Pagano, Logoteta, Conforti, Cirillo, Baffi, and many others of the most eminent men of the time, even the beautiful and accomplished Leonora Pimentel and Luigia Sanfelice, perished by the hand of the executioner. Naples has not yet recovered the blow, and the British name has ever since remained taxed by the Neapolitans with want of faith.

Ferdinand returned to Naples, and increased the prosecutions. The monasteries of the order of St Benedict, and of the Carthusians, who had taken no part in the revolution, but had the misfortune of having great wealth, were suppressed, and their property confiscated to the exchequer. Another decree abolished the *Sedili*, a sort of municipal corporation of Naples, which represented, and in part sustained, the ancient rights and privileges of the kingdom, and the influence of the aristocracy.

Six years after these events, Ferdinand, on the 23d Jan. 1806, was compelled again to seek refuge in Sicily. After the battle of Austerlitz, the peace of Presburg, Dec. 26, 1805, between France and Austria, having left Naples to her fate, a French army, under General Massena, marched upon the kingdom, and entered Naples on the 14th February. A decree of Napoleon, dated Paris, March 30, 1806, proclaimed Joseph Buonaparte king of Naples. After two years, however, another imperial decree, of July 15, 1808, calling Joseph to the throne of Spain, appointed king of Naples Joachim Murat, who had married Caroline, a sister of Napoleon.

It would be long to enter into an account of the new institutions and laws introduced under the French rule into the kingdom. Suffice it to mention that the Code Napoleon was adopted, the Tavoliere system was improved, a tax called *Fondiaria*, of one-fifth part of the revenue from real property, was introduced, the remnants of the feudal system were destroyed, and every sort of jurisdiction restored to the crown; feudal burdens were abolished; serfdom done away with; the use of rivers, lakes, and sea-shores restored

[1] *History of the Kingdom of Naples*, 1734–1825, by General P. Colletta. Translated from the Italian by S. Horner, with a Supplementary Chapter, 1825–1856. Edinburgh, 1858. 2 vols. 8vo.

to all; mixed properties, upon which the feudal lords and the peasantry had certain defined rights in common, were dissolved and divided; the aristocratic order preserved only by titles; monasteries suppressed; privileges of any kind abolished, and all the inhabitants made equal before the law.

Important events were at the same time taking place in Sicily. After the whole of Italy had been occupied by Napoleon, England felt the necessity of strengthening her alliance with King Ferdinand, and securing her retreat into the island. With that view she engaged to pay him subsidies of from L.300,000 to L.400,000 per annum, and to protect the island by an army of at least 10,000 men; the king, on his part, promised to exempt from customs' duties all the provisions required for her army in the Mediterranean, and to close the ports of Sicily against her enemies. In 1810, however, Queen Caroline, being displeased at the English not using all the efforts which she desired to reconquer Naples for her dynasty, opened communications with Napoleon, who having become her kinsman by his marriage with Maria Louisa, gave her hope of regaining that kingdom. Hence she began to make every exertion to create mutual mistrust between the Sicilians and the English, and to drive the latter out of the island. These intrigues on the part of the queen being backed by an attempt from the king to destroy the constitution of the island, rendered an intervention necessary on the part of our government in the affairs of the country.

The Sicilian constitution had undergone but slight alteration during the Spanish dominion. Its parliament consisted of three *braccia* or estates, in the first of which, at the time these events happened, sat 66 prelates and abbots; in the second, or military braccio, 227 noblemen; and in the third, or braccio demaniale, 43 representatives of as many free towns. It met only every four years, but was permanently represented by a committee of 12 members, appointed by the three Chambers, who administered the finances, and were the guardians of the public liberties during the intervals between its sessions. In February 1810, the hereditary prince opened it in the name of the king, and demanded an extraordinary supply of L.180,000 per annum; but parliament having refused to vote more than L.50,000, the Crown, by several edicts of February 1811, ordered some communal and public lands to be sold, and a tax of 1 per cent. to be levied upon the value of every contract. The braccio militare having presented a protest to the king against these unconstitutional proceedings, four of the leading peers, who had signed it, were arrested on the night of the 19th July, and transported to different islets off the coast.

On these occurrences becoming known in this country, our government furnished Lord William Bentinck, who was then commander-in-chief of the British forces in the island, with full powers for intervening in the contest which had arisen between the Crown and the Sicilian nation. The results of Lord William Bentinck's intervention were —1st, The removal of the queen from all concern with public affairs, and eventually her departure from the island; 2d, The recall of the peers who had been deported; 3d, The revocation of the unconstitutional edicts; 4th, The appointment of the hereditary prince as vicar-general of the kingdom; 5th, The consent of the king to a reform of the constitution.

Parliament was accordingly summoned by the Prince Royal, and in November 1812 concluded its reform of the constitution, which, in February 1813, was sanctioned by the king. The new constitution was framed on the model of that of England, the legislative power being vested conjointly in the king, in an Upper House, consisting of barons and bishops, and a Lower House of representatives, elected by the people, and the executive power being exclusively in the hands of the king.

The new Sicilian constitution, however, was not destined to have a long existence, for the fall of Napoleon brought on the restoration of the Bourbons at Naples, who forgot the asylum they had twice found in the island. Whilst the Congress at Vienna was considering whether Naples was to be left to Murat or restored to Ferdinand, the escape of Napoleon from Elba changed the state of affairs. Joachim, who was distrustful of the Congress, in March 1815, declared war against Austria, and entered the Papal territory; whereupon the Congress sitting at Vienna declared him fallen from the throne, and the dynasty of the Bourbons reinstated. After various engagements, the battle of Tolentino, and the treachery of many of Murat's generals, decided the contest. Joachim retired in disorder, and the Austrians entered the kingdom, and encamped round Capua. On the 20th of May the Neapolitan generals Carrascosa and Colletta, the Austrian generals Bianchi and Neipperg, and Lord Burghersh, on the part of England, met at Casalanza, a small house three miles from that fortress, and concluded a treaty, which put an end to the war and to the kingdom of Murat.

Ferdinand returned to Naples in the beginning of June; not Queen Caroline, who had died suddenly in the Castle of Hetzendorf on the 7th September 1814.

Murat ended his days in a rash attempt to recover the kingdom. In the island of Corsica, where after the battle of Waterloo he had sought refuge, he collected a band of two hundred and fifty followers, all personally attached to him, and ready for adventure; and having freighted six vessels, on the night of the 28th September 1815 weighed anchor from Aiaccio, and directed his course to Salerno, where three thousand of his former soldiers, supposed to be discontented with the Bourbons, were stationed. His preparations, however, had been watched by a certain Carabelli, a Corsican, who, though formerly covered with favours by Murat, had volunteered to act as a spy; and the Neapolitan government, being by him informed of Murat's movements, kept a look-out along the coasts. The small fleet sailed prosperously for six days, but on the 7th it was assailed and scattered by a storm, which drove the vessel in which the ex-king himself was near the shore of Pizzo in Calabria. After some hesitation Murat resolved to land at that place; and on the 8th of October, a feast-day, he appeared in the market-place of Pizzo, with twenty-eight followers, who, raising his standard, shouted, "Long live King Murat!" All persons present having remained silent, Murat perceiving how cold his reception was, hastened to go to Monteleone, a populous city, in which he expected to find many warm friends; but being followed up and attacked by a number of devoted adherents of the Bourbons, he gallantly dashed through them, and made for the shore, to regain his vessel. But the vessel was at some distance, and Murat in vain shouted for her, for the captain sailed, carrying away the rich booty he had on board. Murat tried to push off a skiff which lay upon the shore, but at length surrounded and seized, he had the jewels he wore on his cap and breast torn off, was struck in the face and insulted, and, with his companions, dragged into the dungeon of the castle.

The news of the events at Pizzo being transmitted to Naples by telegraph, the government sent stringent orders for Murat's trial and immediate execution. A court-martial, composed of seven officers, three of whom and the attorney-general had been raised by Murat from humble stations, assembled on the 13th, and by a law which he himself had passed seven years before, and which now became the instrument of his own death, condemned him to die as a public enemy, for having attempted to excite the people to rebellion against their lawful sovereign. He was shot the same day in a small court of the castle. He refused to have his eyes bound, and calmly placing himself

in a posture to receive the balls," said to the soldiers, "Spare my face, and aim at my heart." He fell, in his forty-eighth year, grasping in his hands the miniature portraits of his children; and his remains were buried in the church of Pizzo, towards the erection of which he had liberally contributed.

Once firmly re-established on the throne of Naples, Ferdinand began his attack on the liberties of Sicily. Article 104 of the treaty of Vienna recognised him as "king of the *kingdom* of the Two Sicilies." The word kingdom therein introduced, though apparently insignificant, aimed, as it will be seen, at important changes in the government of the country.

By a secret article of a treaty, signed at Vienna on the 14th of June 1815, Ferdinand had bound himself, in resuming the government of his kingdom, "not to admit of any innovation not in accordance either with the ancient monarchical institutions, or with the principles adopted by his imperial and royal majesty in the internal government of his Italian provinces." In conformity with this engagement, in 1816 he promulgated three royal edicts, by which he assumed the new title of Ferdinand I., King of the Kingdom of the Two Sicilies; and on the grounds that the privileges enjoyed by the Sicilians were to be combined with the *unity* of the political institutions, which were to form the public law of the *kingdom*, he united the *two* kingdoms of Naples and Sicily, took the whole of the government into his hands, and virtually and *de facto* annulled both the ancient and the new constitution of Sicily. The Sicilians were only granted the privilege, that all offices and employments, civil and ecclesiastical, in the island should be conferred exclusively upon them. From that time dates the despotic rule of both the continental and the insular divisions of the kingdom.

A summary of the principal events, from 1815 to 1850 having been already given under ITALY, it remains only to add that the condition of the country has not since improved in any degree. A series of state trials, familiar in this country through the powerful appeal against them to the public opinion of all civilised nations by one of our most able statesmen,[1] initiated, in 1850, a system of ferocious reaction, which, far from abating, seems to grow worse with time. Ferdinand II., in 1859, was succeeded by his eldest son Francis II., who is faithfully treading in the footsteps of his father. The supreme and irresponsible authority of the police, and its natural offsprings, want of personal security, persecutions, injustice, terror, and general dismay, are still the order of the day in the Two Sicilies.

CHRONOLOGICAL TABLES.

THE NORMANS, A.D. 1130–1194.

1130. Roger, a grandson of Tancred of Hauteville, is proclaimed King at Salerno.
1154. William I. (the Bad), son of Roger.
1166. William II. (the Good), son of William I.; leaves no issue.
1190. Tancred, Count of Lecce, a natural son of a son of Roger.
1194. William III., son of Tancred.

THE SUABIANS, 1194–1266.

1194. Henry VI., Emperor of Germany, the son of Frederick Barbarossa, having married Constance, the daughter of Roger, claimed the crown, and compelled William III. to abdicate.
1197. Constance reigns alone in the name of her son.
1198. Frederick II. of Hohenstaufen, Emperor of Germany.
1250. Conrad, the second son of Frederick II.
1254. Manfred, a natural son of Frederick II., at first as guardian of Conradin, the only son of Conrad, and afterwards, on the false report of Conradin's death, in his own name.

THE ANGEVINES, 1266–1442.

1266. Charles I. of Anjou, Count of Provence, brother of Louis IX. (St Louis).

KINGDOM OF NAPLES.

House of Anjou.

1282. Charles I. having lost Sicily, remains King of Naples.
1285. Charles II., the Lame (Carlo il Zoppo), son of Charles I.
1309. Robert the Wise, third son of Charles II.
1343. Joanna I., daughter of Charles, only son of Robert.
1381. Charles III. of Durazzo, son of Louis Count of Gravina, and grandson of Charles II.
1386. Ladislaus, son of Charles III.
1414. Joanna II., sister of Ladislaus.
1435. René of Anjou, Duke of Lorraine, called by Joanna II.'s will in opposition to her previous adoption of Alfonso of Aragon. The Angevine dynasty ended in him.

KINGDOM OF SICILY.

House of Aragon, 1282–1501.

1282. Peter, King of Aragon, the husband of Constance, the daughter of Manfred.
1285. James I., the Just, son of Peter; on succeeding to Aragon in 1291, abdicated in favour of his brother.
1291. Interregnum.
1296. Frederick II., brother of James I.
1337. Peter II., son of Frederick, to whom he had been associated on the throne since 1321.
1342. Louis, son of Peter.
1355. Frederick III., a younger brother of Louis.
1377. Mary, daughter of Frederick III., and her husband, Martin of Aragon.
1402. Martin I., on the death of Mary without issue.
1409. Martin II. (I. of Aragon), the father of the last king. Sicily was united to Aragon.
1412. Ferdinand the Just, King of Aragon and Sicily.
1416. Alfonso V., son of Ferdinand, King of Aragon and Sicily.

King of Naples and Sicily.

1442. Alfonso V., called the Magnanimous, having expelled Renato of Anjou from Naples, united the two kingdoms, and assumed the name of Alfonso I. At his death the two countries were again separated.

Kingdom of Naples.

1458. Ferdinand I., a natural son of Alfonso, legitimated by the Pope in 1444.
1494. Alfonso II., Duke of Calabria, son of Ferdinand I., who, on being attacked by Charles VIII. of France, abdicated in favour of his son,
1495. Ferdinand II., who recovered the kingdom from the French, and died at twenty-nine.
1496. Frederick, Prince of Altamura, second son of Ferdinand I. Attacked by Louis XII. of France, and betrayed by his cousin Ferdinand the Catholic, he lost the kingdom in 1501. The Aragonese dynasty ended with him.

Kingdom of Sicily.

1458. John II., a brother of Alfonso, and King of Aragon and Navarre.
1479. Ferdinand II. (Ferdinand the Catholic), son of John II.

THE SPANISH DOMINION, 1501–1707.

Kingdoms of Naples and Sicily.

By the treaty of Granada, November 1500, Louis XII. and Ferdinand the Catholic, agreed to divide Naples; but dissensions having arisen between them, Ferdinand drove the French away, and in 1504 united the whole of Naples to Sicily, already a Spanish possession.

1504. Ferdinand the Catholic, King of Spain.
1515. Joanna of Castile, daughter of Ferdinand and Isabella, who abdicated in favour of her son,
1516. Charles IV., afterwards the Emperor Charles V.
1554. Philip II. of Spain, the husband of Queen Mary of England.
1598. Philip III. of Spain, son of Philip II.
1621. Philip IV., the son of Philip III., by Margaret of Austria.
1665. Charles II., son of Philip IV., by his second wife, Mary Anne of Austria.
1700. Philip V., Duke of Anjou, and grandson of Louis XIV. of France, called by Charles II.'s will to the thrones of Spain, Naples, and Sicily.

[1] *Two Letters to the Earl of Aberdeen on the State Prosecutions at Naples*, by W. E. Gladstone. London: Murray.

THE AUSTRIAN DOMINION, 1707–1734.

Naples.

1707. Charles, Archduke of Austria, second son of Leopold I., and afterwards Emperor, as Charles VI.

1720. Charles VI., Emperor of Germany, and King of Naples and Sicily.

Sicily.

1713. By the treaty of Utrecht, Spain ceded Sicily to the Duke of Savoy.

1718. Spain seized upon Sicily, but in 1720 gave it up to Austria.

THE BOURBONS.

Kings of Naples and Sicily.

1734. Charles of Bourbon, VII. of Naples, a younger son of Philip V. of Spain, by his second wife, Elizabeth Farnese. Succeeded in 1759 to the throne of Spain as Charles III.

1759. Ferdinand III. of Sicily, and IV. of Naples, third son of Charles III. by Amelia Walburga, daughter of Frederick Augustus, king of Poland.

Naples.

1799. After five months of Republican government, Ferdinand retook possession of the kingdom.

Sicily.

The Bourbon dynasty continued without any interruption.

THE FRENCH DOMINION, 1806–1815.

1806. Joseph Buonaparte proclaimed king on the 14th of January.

1808. Joachim Murat, proclaimed king of Naples by a decree of Napoleon, of 15th July.

THE BOURBONS (continued).

Kingdom of the Two Sicilies.

1815. Ferdinand IV., by the treaty of Casalanza, May 20, 1815, obtains possession of Naples. In 1816 he assumed the name of—

1816. Ferdinand I., King of the Kingdom of the Two Sicilies.

1825. Francis I., his son by Caroline of Austria, sister of the Emperor Joseph II.

1830. Ferdinand II., son of Francis, by his second wife, the Infanta Isabella of Spain.

1859. Francis II., the reigning king, eldest son of Ferdinand II., by his first wife, Maria Christina, daughter of Victor Emmanuel I., king of Sardinia. He succeeded his father on the 22d of May 1859. (* * *)

SICULIANA, a town of Sicily, in the province and 9 miles N.N.W. of Girgenti. It occupies an unhealthy situation, in the neighbourhood of the most considerable sulphur mines in the island. Some trade is carried on in corn and sulphur. The ancient Camicus is supposed to have been situated near this town. Pop. 6000.

SICYON (Σικυών, modern *Vasilika*), a celebrated city of ancient Greece, in Achaia, about 2 miles from the south shore of the Corinthian Gulf, and about 10 N.W. of Corinth. The situation is one of the finest of any of the cities of Greece. It stands on a hill between the rivers Helisson and Asopus, and commands a wide prospect over the fertile plain of Achaia on the west; on the east, as far as the lofty hill that sustained the citadel of Corinth; while, on the north, the eye ranges over the waters of the gulf to the mountains of Parnassus, Helicon, and Cithaeron beyond. The hill is triangular, and round its edges ran the walls of the city. Its southern portion being slightly elevated above the rest, formed the Acropolis. Like most other large Greek cities, Sicyon contained an agora or market-place. a theatre, a gymnasium, and innumerable temples. Of the last, the most important seems to have been that of Apollo, the patron of the city, in the market-place. The streets were regularly laid out, crossing one another at right angles, These may still be traced; but very few of the buildings have been preserved. There are, however, some remains of the theatre, and also of a *stadium* or race-course, both for the most part cut out of the ledge of rock between the upper and lower city. Sicyon is said to have been one of the most ancient cities in Greece; and there are many legends more or less improbable concerning its early history. During all the time when anything definite can be known about it, the town seems to have been peopled partly with Dorians and partly with Ionians; and for the greater part by far of this period the former race were the dominant party. The chief exception to this was an interval of more than 100 years, from about B.C. 676 to 560, during which it was governed by successive tyrants of the house of Orthagoras. an Ionian family. The last of these was Cleisthenes, whose daughter Agarista was married into the illustrious Athenian family of the Alemaeonidæ, and became the mother of a more famous Cleisthenes, the consolidator of democratic power at Athens. During the most stirring times of Greek history, Sicyon makes no great figure. In all the wars it was a steady adherent to Sparta, and opposed to Athens. It was more famous for its painting and sculpture than for political influence, and the city was rich in works of art. It gave its name to one of the great schools of painters in Greece, which was founded by Eupompus, and distinguished by the genius of Apelles. Sicyon was also the birthplace of the sculptor Lysippus. After the Roman conquest of Greece it fell into decay, though it continued to exist down to the Christian era.

SIDDONS, MRS (whose maiden name was Sarah Kemble), the greatest actress that ever trode the stage, was born at Brecon, in South Wales, on the 5th of July 1755. Roger Kemble, her father, was manager of a provincial company of players, and amongst this class of persons he seems to have held a highly respectable rank. Sarah, who was his eldest daughter, appeared very early on the stage, and went the usual round of juvenile characters without exciting much expectation. At the age of eighteen she married Mr Siddons, an actor in her father's company, soon after which event she removed to Cheltenham, where she attracted some attention, and was recommended to Garrick. Her first appearance on the London boards was not successful, simply because she never had a proper part assigned her. Mrs Siddons accordingly returned to the provinces much mortified; but the praises showered upon her by such audiences as those of York, Manchester, and Bath, induced the managers of Drury Lane to re-invite her to the metropolis. Her re-appearance took place on the 10th October 1782. The character which she chose was that of Isabella in *The Fatal Marriage*. The effect of that performance was extraordinary and unparalleled. It gave a shock of wonder and delight to the public mind, like the news of some great and unexpected victory. On that night, Mrs Siddons at once took possession of the tragic throne, on which, for thirty years, she reigned without a rival. Some idea of the excitement which she created may be learned from the fact, that "the grave and reverend seignors" of the English bar presented her with a purse of one hundred guineas. During the season Mrs Siddons played Euphrasia, Jane Shore, Calista, and for her two benefits, Belvidera and Zara. In all of these characters she greatly added to her fame; the public were astonished at the vastness of her powers, and tragedy became the fashion. In subsequent seasons she increased her circle of characters, adding from Shakspeare those of Lady Macbeth, Constance, Isabella, Queen Katherine (the most chaste, beautiful, and perfect performance that ever drew a tear), Rosalind (not in her line, for she was altogether too stately and heroic for comedy), Desdemona, Volumnia, Portia, Hermione, Imogene, and a few others. This list shows that her range was surprising, but she was not equally excellent in all her parts. Her comedy never gave great satisfaction, although there was occasionally much to admire in it. When the metropolitan season closed, it was the custom of this, as it is of every great actor, to visit the principal cities of Ireland, Scotland, and the provinces of England. Everywhere she enchanted the lovers of the drama. She became a favourite with their majesties, and was in the habit of read-

ing plays to them, an occupation of more honour than emolument. However, Mrs Siddons, by her professional exertions, realized a fortune equal to her wishes, and retired from the stage in 1812. Her death took place on the 8th of June 1831, in her seventy-sixth year.

The symmetry of this great actress's person was most captivating. Her features were strongly marked, but finely harmonized; the flexibility of her countenance was extraordinary, yielding instantaneously to every change of passion; her voice was plaintive, yet capable of firmness and exertion; her articulation was clear, penetrating, and distinct; above all, she was completely mistress of her powers, and possessed that high judgment which enabled her to display all her other qualifications to the greatest advantage. One of Mrs Siddons' highest endowments, if not her very highest, was the power of identifying herself with the character which she personated. The scenes in which she acted were to her far from being a mere mimic show; so powerfully did her imagination conjure up the reality, that the tears which she shed were those of bitterness felt at the moment. From her frown of proud disdain and scorn, the very actors themselves shrank with something like terror. Her greatest characters were Katherine in *Henry VIII.*, and Lady Macbeth, in which she manifested a dignity and a sensibility, a power and a pathos, never equalled by any female performer. Lastly, Mrs Siddons was truly an original; she copied no one, living or dead, but acted from nature and herself. In all the relations of life her conduct was most exemplary. "She was more than a woman of genius," says the poet Campbell, who knew her well, "for the additional benevolence of her heart made her an honour to her sex, and to human nature." (J. F. S.)
